Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.

+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.

+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.

+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

SUPPLEMENT TO "THE ELECTRICAL ENGINEER," DEC. 30, 1904.

THE

ELECTRICAL ENGINEER.

A WEEKLY JOURNAL OF ELECTRICAL ENGINEERING,

WITH WHICH IS INCORPORATED

"ELECTRIC LIGHT."

VOL. XXXIV. (NEW SERIES.)

FROM JULY 1, 1904, TO DECEMBER 30, 1904.

LONDON:

Printed and Published for the Proprietor by BIGGS & Co., at "THE ELECTRICAL ENGINEER" Offices, 139-149, Salisbury-court, Fleet-street, E.C.

1904.

Digitized by Google

INDEX TO VOL. XXXIV. (New Series.)

NOTE.—General Articles, Correspondence, and Companies' Meetings are indicated by heavier type (thus, 280) than the Notes and Business Notes, references to which are shown by light type (thus, 290).

A.

Accidents, 196, 319, 465, 679, 794

Accumulators, etc.:
A.B.P., 32
Batteries with Reversible Boosters, C. Turnbull, 918
Dayton, The, 650
Edison, The, A. E. Kennelly and S. E. Whiting, 637
Mercury Sulphate and Standard Cells, 942
Non-Explosive Storage Battery, 470
Questions and Answers on, see QUESTIONS AND ANSWERS
for Traction, 289, 637

Adams, W. P., Combination of Dust Destructors and Electricity Works, 925
Addresses, New or Change of, see "Removals"
Agencies, 211, 393, 464, 715, 780
Air Gaps, The Magnetic Resistance of, 484
Aldworth, J., Cars, Their Equipment and Maintenance, 479
Alternate and Direct Currents, The Relative Disruptive Effects of, 449
Alternate-Current Instruments, The Use of Iron in, Dr. Sumpner, 896, 849, 889
Alternating Currents, The Influence of Frequency on the Electrolytic Action of, 397
Alternators, see DYNAMOS
Aluminium, B. Pool, 625
Aluminium Alloys, The Electrical Conductivity of Certain, etc., E. Wilson, 344
American Oil-Engine Central Station, 951
American Student, The, 649
Ammeter Connection, 398
Andrews, L., High-Tension Switchgear, 918
Andrews, L., Methods of Cable Laying, 741
Anti-Electrocution Patent, 64
Appointments, 148, 557, also see "Personal"
Appointments Vacant, see each Issue

Arc Lamps:
Couplings for, 59
Double-Carbon, 823
Effect of Pressure on Light from, 685
Meridian, The, 239
Miniature, The, 352
Open, and Ice, 217
Union Company's, 854

Arc Spectra, Spark Lines in, 650
Arc, Temperature of, 689
Arc, The Singing, 653
Artificial Loads for the Dissipation of Electric Power, F. H. Davies, etc., 127, 199, 237, 309, 343
Atmospheric Pressure, 37
Australian Trade Marks, 650
Automobiles, 182, 361, 409, 468, 469, 872
Average Speed, etc., A. R. Fearnley, 697
Awards, 660, 685, 781, 871

B.

Balance-Sheets, etc.:
Ashton Accounts, 269
Ayr Accounts, 521
Bexhill Accounts, 205
Blackburn Accounts, 60
Bridgend Accounts, 315
Brighton Telephone Accounts, 636
Cardiff Accounts, 275
Cheltenham Lighting (J. Swinburne), 744
Chester Tramways, 240
Dublin Corporation Electricity Works (R. Hammond), 425
Dublin and Lucan Railway, 208
Dudley Accounts, 600
Eastbourne Accounts, 600
East Ham Accounts, 420, 459
Eccles Accounts, 315
Glasgow Telephone Accounts, 152
Gloucester Accounts, 59
Greenock Accounts, 665
Hackney Accounts, 600
Hammersmith Accounts, 459
Harrogate Accounts, 737
Ilford Accounts, 205
Leyton Accounts, 707
Liverpool Overhead Railway, 207
Longton Accounts, 459
Manchester Street Lighting (S. L. Pearce), 734
Norwich Accounts, 161
Oldham Accounts, 125
Poplar Accounts, 315

Balance-Sheets, etc. (*continued*):
St. Helens Accounts, 353
St. Pancras Accounts, 39
Southampton Lighting Accounts, 394
Southwark Accounts, 333
Stockton-on-Tees Accounts, 352
Wallasey Tramways, 305
West Ham Tramways, 892
York Accounts, 707

Balfour, Right Hon. A. J., Address to British Association, 259
Ballydonerraile (Poetry), 772
Banister, A. N., Tramway Car Wheels, etc., 698
Banting, P. E., and G. A. Neild, Commutation of Continuous-Current Dynamos and Motors, 444
Batteries with Reversible Boosters, C. Turnbull, 918
Beilby, G. T., Hard and Soft States in Metals, 39
Bellamy, C. R., Presidential Address to Municipal Tramway Association, 476
Belt Calculation, A New Rule for, 91, 163, 236
Benischke, G., Magnetic Resistance of Air Gaps, 484
Bennett, A. R., Telephone Rates and Government Purchase, 929
Birthday Honours, 2, 705
Bitumen, W. P. Digby, 627
Blaine, R. G., Wireless Telegraphy, 19, 56, 78, 200, 227, 267, 343
Blakeway, H. J., The Financial Position of Municipal Electrical Undertakings, 124
Bleaching, Electrolytic, Dr. Gradenwitz, 694
Board of Trade Regulations, Revised, 319, 364
Boiler-House Economies, R. S. Downe, 120
Boilers, Mechanical Draught for, W. Yates, 167
Boilers, Naval, Report on, 253
Boilers, Water-Tube, 794
Borough Councillors, The Education of, 952
Bradford's Burnout, 828
Briggs, E. R., Metric System, The, 561
Brislee, F. J., The Potential of the Hydrogen-Oxygen Cell, 770
Bristol Electricity Works' Fire, H. F. Proctor, 88
British *v.* Foreign Joists, 484
British Mineral Production in 1903, 688
Bruce Peebles and Co.'s Works, 757

C.

Cable-Estimating Clerk's Complaint, The (Poetry), 812
Cable Laying, L. Andrews, 741
Cables for High Voltages, Testing of, 448
Calcium Carbide, 38
Calorimetry of Exhaust Gases, B. Hopkinson, 336
Campbell Swinton, A. A., Electricity from Water Power, 294, 560
Canal Traction, Mechanical, F. H. Davies, 277
Carbon, 37, 109
Car Equipment and Maintenance, J. Aldworth, 479
Catalogues, see "Trade Notices," also 284
Cathode Rays, Chemical Effects of, 39, 900
Central-Station Meter Department, The Organisation and Management of, A. J. Cridge, 46
Centre Poles in Streets, 253
Change of the Shift (Poetry), 665
Cheltenham Street Lighting Report, J. Swinburne, 744
China, Trade Marks in, 363, 649
Churcher Alternating Rectifier, 674
Circle Diagrams for Facilitating Economical Working, 74
Cleanliness *v.* Insulation (Poetry), 526
Clerk, D., Flame Temperatures in Internal-Combustion Motors, 330
Coal, Forms of Sulphur in, 253
Cobalt and Nickel, 959
Colonial Notes, 78, 358
Commercial Practicability of Electric Traction by Surface Contacts, C. E. C. Shawfield, 12, 44
Commonwealth Steam-Turbine Accident, 457

Companies' Meetings, Reports, etc.:
Aberdeen Suburban Tramways, 389
Amazon Telegraph, 715
Anglo-American Telegraph, 172, 200, 571
Anglo-Argentine Tramways, 142, 465, 533
Angus Electric Light, etc., 357
Aron Meter, 777, 856
Babcock and Wilcox, 463
Baker-street, etc., Railway, 213
Bath Electric Tramways, 640, 643
Blackheath, etc., Electric Light, 175
Blackpool Electric Tramways (South), 961
Blackpool and Fleetroad Tramroad, 208
Bolckow-Vaughan, 317

Companies' Meetings, etc. (*continued*)
British Aluminium, 856
British Columbia Electric Railway, 639, 676
British Electric Traction, 25, 96, 935, 961
British Insulated, etc., 318
British Westinghouse, 819, 855
Buenos Ayres Tramways, 60, 65, 133, 461, 531
Bury, etc., Tramways, 354
Calcutta Electric Supply, 464
Calcutta Tramways, 498
Callender Cable, etc., 607
Cape Electric Tramways, 29, 711, 777
Central Electric Supply, 752
Central London Railway, 136, 207, 242
Charing Cross and Strand Electric Supply, 210, 247
Chelsea Electric Supply, 209, 964
Chilian Electric Tramway, etc., 354
Chili Telephone, 96, 172
Chloride Electric Storage, 243
City of London Electric Light, 31, 138
City and South London Railway, 134, 136, 206
Consolidated Electrical, 207, 243
County of London Electric Supply, 174
Crompton and Co., 207, 243
Cuba Submarine Telegraph, 568
Derbyshire and Notts Electric Power, 319, 780
Dick, Kerr, and Co., 461, 496
Direct Spanish Telegraph, 464
Direct United States Cable, 134, 171
Dublin and Lucan Railway, 136, 208, 317
Dublin Tramways, 207
Eastern Extension, etc., Telegraph, 31, 711, 777
Eastern Telegraph, 142, 172, 607
Edison and Swan United, 568, 603
Edmundsons' Electricity, 103, 96, 172
Electric Construction, 60, 66, 133
Electric and General Investment, 96, 860
Electric Power Storage, 67, 97
Electric Railway and Tramway Carriage, 383, 532
Electric Traction, 99
Electricity Supply Company of Spain, 715
Electrified Timber Seasoning, etc., 461
Electrolytic Alkali, 604, 640
Electro-Peat Coal, 280
Ferranti, Limited, 461, 532
Flying Machines, 961
Galloways, Limited, 900
General Electric, 134, 206
Geneva Tramways, 777, 779, 856, 935
Great Eastern Railway, 206
Great Northern and City Railway, 243, 280
Henley, W. T., Telegraph Works, 357
Hove Electric Lighting, 464
India Rubber, etc., 895, 933
Indo-European Telegraph, 571
Industrial Storage Battery, 748
Isle of Thanet Tramways, etc., 856, 933
Isle of Wight Electric Light and Power, 25
Kalgoorlie Electric Power, etc., 280, 317
Kent Electric Power, 319
Lancashire Power Construction, 896
Liverpool Overhead Railway, 177, 207, 280
London Electric Supply, 139
London United Tramways, 317
Manx Electric Tramways, 933
Marconi Wireless Telegraphy, 643
Mashonaland Railway, 321
May-Oatway Fire Appliances, 819
Mersey Railway, 496
Metropolitan District Railway, 177, 206
Metropolitan Electric Supply, 67, 96, 133, 174
Metropolitan Electric Tramways, 320, 779
Metropolitan Railway, 172
National Telephone, 103, 97, 172
Newcastle Electric Light, 174
New General Traction, 61, 96
North Metropolitan Tramways, 176, 212
North Wales Power, etc., 100
North-Western Electricity, etc., 676
Norwich Tramways, 533, 568, 604
Oriental Telephone, 668
Power Gas, 896
Rand Central Electric Works, 318
Raworth's Traction Patents, 899, 962
Rhodes Electric Manufacturing, 715
Rhodesian Railway, 321
Rosario Electric, 711
St. James, etc., Electric Light, 139, 680
Scottish Central Power, 573
Snowdon's Flame Preventer, 781
South Lancs. Traction, 283, 497, 558
South London Electric Supply, 138, 607
South Metropolitan Electric Light, etc., 285, 392
South Staffs Tramways, 933
South Wales Power, 896
Standard Metal Engraving, 781

THE

ELECTRICAL ENGINEER.

No. 1, Vol. XXXIV. LONDON, JULY 1, 1904. PRICE 3D.

NOTES.

New Measuring Instrument.—A French engineer, M. Mesnager, has invented an apparatus for measuring with great precision the elastic deformation of metals under strain.

Junior Institution of Engineers.—A visit is to be paid to Dover on Saturday, the 9th inst., when the South-Eastern and Chatham Railway turbine steamer "The Queen," the Admiralty Harbour Works, and the works of the Dover Harbour Board will be inspected. There will be a reception by the Mayor and Mayoress at the town hall in the afternoon. Train leaves Victoria at 9.55 a.m.

Huddersfield Sewerage Extension. — At the enquiry conducted by the Local Government Board last week into the application of the Huddersfield Corporation for sanction to borrow £135,000 for extensions of the sewerage works, Mr. K. F. Campbell, the borough engineer, explained that the new plant necessitated by the peculiar circumstances of the town will be operated electrically, by which a substantial saving would be effected on the present annual charges.

Electric Launch.—A new attraction on Derwentwater this year will be an electric launch, which will be worked from the Lodore Hotels. The vessel, which is named the "Iris," is 45ft. long, with an 8ft. beam and a draught of 16in. She is propelled by a screw making 650 revolutions per minute. The storage batteries will be charged at Lodore, where there is a generating station, with turbine power gained from the water of Lodore Falls. The boat will be sailed under Board of Trade regulations, and is constructed to accommodate 52 passengers. This combination of a water-power plant to charge an electric launch is excellent.

Society of Arts Conversazione.—On Monday a large gathering, representative of the arts and science section of the community, testified to their appreciation of the Society of Arts plan of holding the annual conversazione in the open air. Sir William Abney, K.C.B., D.C.L., D.Sc., F.R.S., chairman, and other members of the council, held a reception at the entrance to the conservatory from 9 to 10 p.m. The tropical house, containing the Victoria Regia (the giant water lily) and other interesting tropical plants, was thrown open to visitors. There was also a remarkably fine collection of growing and cut roses and other flowers by Messrs. William Paul and Son, of Waltham Cross. The gardens and conservatory were transformed into fairyland by festoons of coloured lamps, huge Christmas trees, and other charming devices. The programme further contained selections by the string band of the Royal Artillery, the band of H.M. Irish Guards, and a vocal and instrumental entertainment under the direction of Mr. H. Tipper.

The Thermo-Galvanometer.—This is the designation of the instrument just invented by Mr. W. Duddell for measuring very weak alternating currents, which has lately been the subject of some experiments in Bushey Park by Sir William Preece, Mr. John Gavey, and Mr. R. T. Glazebrook, on behalf of the Post Office, the object being to test the strength with which wireless messages arrive at the receiving station. An extremely fine strip of gold leaf or platinum, stuck on to a piece of glass, is employed, and this, being subjected to the electric waves caught in the receiver, becomes slightly warmed. The degree of heat can be ascertained by means of Prof. Boys's radio-micrometer, and so the strength of the current is gauged. Thus the invention may be of great service in the development of inland wireless telegraphy by demonstrating whether intermediate objects, such as electric railways, metallic deposits, or mountains, exercise any effect upon the waves; and it also provides a means of comparing different systems. The results of the experiments have not yet appeared in detail, but they are stated to be of an enlightening character.

"The Central."—We have received No. 3 of the first volume of this journal, which is the official organ of the Old Students' Association of the Central Technical College. It is quite up to its predecessors, both in the matter and in method of production. It commences with a reference to the retirement of Prof. Unwin, who for so many years has been head of the civil and mechanical engineering department. Besides organising the college, he has held the position of professor since 1884. The other articles consist of "Popular Motorcars," by M. O'Gorman; "The Mechanism of Combustion," by Prof. H. E. Armstrong; "The Manufacture of Wood Pulp," by R. W. Sindall; "The Elongation Equation for Ductile Test Bars," by J. W. Hayward; and some editorial comments on the Mosely Educational Commission, special reference being made to the views of Profs. H. E. Armstrong and W. E. Ayrton. Prof. Armstrong's opinions on the education of girls are, of course, hostile, and the professor will see that there is an atmosphere about them not unlike that in Section L of the British Association when he is expressing his opinions on this critical subject.

The Compensation Limit. — The action of the Sheffield Corporation in seeking to limit its liability for accidents occurring on the municipal tramways to £25 by publishing a notice on the cars and the backs of the tickets has given rise to considerable discussion, some of the members of the Corporation itself dissenting from the step. The contention of the Corporation is that, having reduced the fares, they are entitled to limit their liability, but there is no precedent to support this view, and the idea that the mere passing of a by-law, even when it has received the approval of a Government department, relieves a public undertaking from the responsibilities imposed by the Statute-book has, of course, already been proved a fallacy.

Digitized by Google

At a recent meeting of representatives from the various municipalities on the inter-running question the subject was alluded to, the general opinion being that the attitude adopted by the Sheffield Corporation was untenable, and indeed, we think that there can scarcely be room for doubt. The point will, however, be contested shortly, a local councillor having carried out his threat of refusing to accept a ticket, and being consequently unable to produce one when called upon to do so by the inspector. The Corporation have served a summons upon him. If a claim just made by a passenger of £50 as compensation is made the subject of an action, the question will be raised in a specific form.

Royal Meteorological Society.—The Prince of Wales has consented to become a patron of this institution. At the last meeting of the society, Captain D. Wilson Barker, president, in the chair, the Rev. C. F. Box gave an account of some curious "Effects of a Lightning Stroke at Earl's Fee, Bowers Gifford, Essex, April 13, 1904." A thunderstorm occurred during the early morning hours, and about 3 a.m. there was a blinding flash, lighting up the whole neighbourhood for miles around, followed immediately by a crashing explosion. One person stated that he saw what appeared to be a cylinder, and another person a ball of fire, descend, and then explode, "casting darts" in all directions. On careful examination in daylight, it was found that in an oatfield, which had recently been dredged, there were three distinct sets of holes, ranging from 9in. down to about 1in. in diameter. The holes, which were perfectly circular, diminished in size as they went downwards, and remained so on to the perfectly rounded ends at the bottom. Upon digging sectionally into the soil, which is stiff yellow clay, it was found that the holes were "as clean cut as though bored with an auger." An interesting discussion followed the reading of this paper. A paper by Mr. A. Laurence Rotch, of the Blue Hill Observatory, U.S.A., describing "An Instrument for Determining the True Direction and Velocity of the Wind at Sea," was, in the absence of the author, read by the Secretary.

The Inter-Running Question.—Undeterred by their reverses before the two parliamentary committees, the Newcastle Corporation have been in further conference with the representatives of the chief municipal authorities, with a view to securing the elimination of the inter-running clause in the Tyneside Tramway Company's Bill, which came before the House of Commons last night for third reading. Meantime, the promoters have issued a statement defining their position very succinctly. They refer to the desire of the councils of the intermediate districts that there should be a through service, and state that manfacturers employing thousands of hands in such localities have petitioned in favour of the Bill. Another point to which they call attention is that when the Corporation obtained sanction to laying their line through Walker, the chairman of the House of Commons committee remarked, "Of course, the idea is that there shall be a through service ultimately." The terms of user are left by the Bill to the Board of Trade, failing agreement; and the company offered in committee to insert a provision that each party should take the net profits earned on its own lines. In conclusion, the company refer to the precedents for inter-running afforded by other large cities. It is obvious, however, that the Corporation intend to contest the question to the very end, so that there will be an opportunity for Parliament to pronounce its verdict on this vexed subject.

Birthday Honours.—The list of appointments made to celebrate the birthday of King Edward VII. this year include a number of names which are interesting to engineers. The first on the list of new members of his Majesty's Most Honourable Privy Council is Charles Booth, Esq. This successful shipowner of Liverpool is known all over the world as the author of a series of volumes dealing with the problems of life incidental to the poor quarters of London. His statistical works are most valuable, and his views on the housing of the working classes have much to commend them. In this branch of his work he deals largely with the improved means of transport provided by electricity. Amongst the new knights appear the names of Prof. James Dewar, F.R.S, Mr. G. S. Gibb, and Mr. W. Lloyd Wise. Prof. Dewar is so well known in the scientific world that it seems redundant to mention the many discoveries of which he has been the author. He was the co-inventor with Sir Frederick Abel of cordite, and the experiments which he conducted on materials at extremely low temperatures are historic. Mr. George Gibb has been general manager of the North-Eastern Railway for the past 13 years. It is largely due to his initiative that the suburban lines around Newcastle have been electrified. This forms an excellent example of the untiring energy shown by Mr. Gibb in the management of the railway, and of his readiness to make use of the inventions of science to improve the public service. Mr. Lloyd Wise is a patent expert, and has assisted innumerable inventors, including a large number of electrical engineers. He was the first president of the Chartered Institute of Patent Agents, and his opinion on scientific questions is often called for in the courts.

Institution Conversazione.—At the conversazione of the Institution of Electrical Engineers on Tuesday, held as usual at the Natural History Museum, Cromwell-road, South Kensington, about 1,500 persons were present. The guests were received by Mr. R. K. Grey (president) and Mrs. B. Hopkinson, Mr. Alexander Siemens (president-elect) and Mrs. Siemens, and the following members of the council: Major-General C. E Webber, C.B., R.E., and Sir Henry Mance, C.I.E. (past presidents), Mr. W. H. Patchell, Mr. J. E. Kingsbury and Mr. W. M. Mordey (vice-presidents), and Mr. R. Hammond (hon. treasurer). Among those present were Prof. H. E. Armstrong, F.R.S., Mr. A. Acland Hunt, Prof. W. E. Ayrton, F.R.S., Mr. T. O. Callender, Prof. H. L. Callendar, F.R.S., Mr. W. R. Cooper, Mr. W. G. Cavendish Bentinck, Colonel R. E. Crompton, C.B., Sir J. H. Bergne, K.C.M.G., Mr. S. Dobson, Mr. W. Duddell, Prof. J. D. Everett, F.R.S., Mr. Frank Gill, Mr. J. Gavey, C.B., Dr. R. T. Glazebrook, F.R S., Mr. H. E. Harrison, Mr. H. Hirst, Mr. J. S. Highfield, Mr. C. Hawksley, P.P.I.C.E., the Hon. Sir A. R. Jelf, Lord Kelvin, O.M, G.C.V.O., Prof. A. B. W. Kennedy, F.R.S, Mr. G. C. Lloyd (secretary), Lady Maxim, the Mayor and Mayoress of Colchester, Mr. P. V. Luke, C.I.E, Mr. C. O. Mailloux, Sir W. H. Preece, K.C.B, F.R S., the Hon. C. A. Parsons, F.R.S., Sir W. Ramsay, K.C.B., Prof. H Robinson, Colonel Sir B. Scott, K.C.I.E., Mr. C. P. Sparks, Mr. J. W. Swan, F.R.S., Mr. James Swinburne, Mr. A. A. C. Swinton, Dr. W. E. Sumpner, Mr. C. F. Von Siemens, Mr. C. E. Spagnoletti, Prof. S. P. Thompson, F.R S., Sir J. I. Thornycroft, LL.D., F.R.S., Colonel J. K. Trotter, C.B., C.M.G., Sir C. Tupper, G.C.M.G., C.B., Mr. G. G. Ward, Major-General R. Wace, C.B, R.A., Mr. C. H. Wordingham, Mr. E. O. Walker, C.I.E., Colonel Sir H. A. Yorke, R.E. During the evening the string band of the Royal Engineers, by permission of Major-General Sir Reginald Hart, played in the central hall, and the Westminster Abbey Quartette, consisting of Mr. J. A. Brown, Mr. E. Dalzell, Mr. F. Norcup, and Mr.

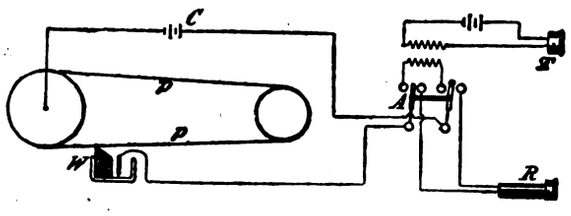
B. Mills, performed a programme of glees and part-songs in the bird gallery.

Electro-chemical Phonograph.—We take from the columns of the *Scientific American* the following description of an interesting electro-chemical phonograph devised independently by Messrs. Nernst and Lieben. Instead of using magnetic action on a continuous band, as in the Poulsen phonograph, the inventors use electro-chemical action. As will be seen in the diagram, a platinum band, *p*, passes over two pulleys which are operated by a motor.



Against the band presses a wedge of wood, W, partly immersed in an electrolyte contained in the glass vessel. Near it is an electrode which is connected to one of the contact points of the switch, A. At T is a telephone transmitter which may be connected in the circuit through a battery and an induction coil, and at R a receiver which may be thrown in. To produce the record the transmitter is connected in; then the band is passed again, and the reproduction may be heard in the receiver. A supplementary battery, C, is also used. Under the influence of the telephone currents an electrolytic action is produced, and the platinum band becomes polarised successively, the action being analogous to the magnetic band of the Poulsen phonograph. Upon passing the band a second time and connecting the receiver, the reproduction is heard, and its sharpness and durability depend on the kind of electrolyte used. But it is remarkable that for reproducing the record an additional E M.F. is necessary in the telephone circuit, supplied by the battery, C, and that within certain limits the audition is better as the battery is stronger. This phenomenon is difficult to explain, as it would be supposed that the currents are produced by the discharge of the polarised electrode, and in this case the addition of a constant E.M.F. should have no action, since it is only the variation of current which produces the effect. It may also be explained by a simple variation of resistance in the circuit, but it is difficult to suppose that such a variation in resistance could be caused by the polarisation of oxygen or hydrogen on the platinum. Besides, M. Lieben has found that the same effect is produced, when the resistance is not varied, in the case of a silver band and a solution of double cyanide of silver and potassium. He has made a number of researches with different forms of the apparatus, and concludes that the phenomenon cannot be explained by polarisation alone. On the other hand, the idea of a resistance variation will not account for all the effects. A third hypothesis is based on the variation of the friction of polarised electrodes observed by Edison. To efface the record, a compress wet with acid is pressed against the band. It is still better to connect it with a pole of the battery, when a continuous electrolytic action is produced, which acts like a brush to efface the record.

The Detection of Arsenic Electrolytically.—The *Lancet* of June 25 contains an abstract of a paper contributed by Mr. W. Thompson to the *Proceedings* of the Manchester Literary and Philosophical Society on the electrolytic method of detecting and estimating minute quantities of arsenic. In consequence of the difficulty of obtaining zinc absolutely free from arsenic for use in the hydrogen generator in the Marsh-Berzelius method, it was suggested some time ago by Lord Kelvin that an electrolytic method of liberating hydrogen might be devised. Mr. Thompson's paper gives the results of a series of tests made with the apparatus designed to carry out Lord Kelvin's idea. It was found to be impossible to get arsenical mirrors by this apparatus when using arsenic in less quantities than one three-hundredth of a grain of arsenious acid per gallon, employing about 20 cubic inches of liquid in the apparatus. Except for pure granulated zinc the use of metals other than platinum as the cathode proved unsatisfactory. With a piece of granulated zinc as the cathode stronger mirrors were obtained than were given by the platinum cathode apparatus, but when the quantity of arsenic came down to a thousandth of a grain the result was not equal to the standard produced by the Marsh-Berzelius method. On employing a rod of pure zinc as cathode, however, it was found that the electrolytic method was as delicate as the Marsh-Berzelius process for the detection and estimation of most minute quantities of arsenic. A suggestion was made that frothing could be prevented in the case of experiments with beer by the addition of amyl alcohol without interfering with the test, but Mr. Thompson's investigations show that the delicacy of the test is considerably impaired thereby, though small quantities of invert sugar do not appear to make any serious difference. In conclusion, Mr. Thompson finds that by using 25 cubic centimetres of beer, as recommended by the committee appointed by the Inland Revenue Commissioners in connection with the matter, and completely destroying the organic matter, a very faint mirror is produced when a one-hundredth of a grain of arsenic per gallon is present, but when the beer is used direct with amyl alcohol no mirror at all is produced. It would appear, therefore, that this direct method fails to detect an amount decidedly greater than that which the committee consider sufficient to condemn the sample. The results, taken all round, suggest that the electrolytic method may prove of some value, though for extreme delicacy it has apparently not yet given results equal to those of the older process.

Electrical Engineers (R.V.).—The camps of this corps begin this month, and are to be held each week until the end of August. The corps is unique in its arrangements for the yearly camps. Each man selects the most convenient date for his training, and, as far as possible, is allowed to exercise a choice of place. The plan has many advantages. Owing to the number of camps each year—some 17 or 18—the number of men at any station at once is comparatively small, and each member secures a most efficient training, and at the same time has a very enjoyable outing. Thus, the highest efficiency is maintained without interfering with the convenience of the men. The work consists of coast-defence work, including searchlights and submarine mining. Camps are held at most of the southern coast Royal Engineer stations—this year at the Isle of Wight, Weymouth, Falmouth, Plymouth, Portsmouth, Sheerness, Felixstowe, Gravesend, and, it is hoped, Dover and the Scilly Isles. Some of these are mobilisation camps. An Easter camp was also held this year at Weymouth to meet the convenience of men unable to get away in the summer. In addition, the corps sends a big detachment of men annually to assist in the naval manœuvres, and it is hoped they will also attend the military manœuvres this year in order to work the field searchlights. Between camps instruction goes on at headquarters, the corps being well equipped with service pattern oil-engines (stationary and portable), dynamos, searchlights, and complete submarine mining outfit. The members show extreme

Digitized by Google

keenness over their technical work, its character and instructive nature appealing greatly to them. The corps is recruited largely from students of Cambridge University, Royal School of Mines, the Central Technical College, and engineering colleges; also from men actually employed in electrical works. The corps has several sub-stations in different parts of the country, at which members can receive technical instruction. Week-end classes are held at headquarters, for which the country members come up to town. The chief outlying stations are at Cambridge, Winchester, Chelmsford, Loughborough, and Woolwich. Mr. Horneby has just presented the corps with a 1-h.p. engine, which it is intended the men shall take apart and build up for themselves, so that they may know all the inner workings of an oil-engine. This year very successful night manœuvres were held at Wimbledon Common and Hampstead Heath, the portable search-light projectors used by the corps at the front being called into service. Under the command of Colonel Crompton, C.B., the future of the Electrical Engineers looks very promising.

Turbine Test.—The *Electrical World* of New York gives some particulars of an elaborate test of a Westinghouse-Parsons 400-kw. steam turbine at the works of the Westinghouse Machine Company, East Pittsburg. The condensed water was measured at intervals of 10 minutes, and the brake horse power was determined by means of a water dynamometer of the Froude type. The duration of the tests was two hours for the full load test with 100deg. superheat, and one hour for most of the other tests, a few being of shorter duration. The accompany table gives the results of the principal test.

Dry Saturated Steam.	Over-load.	Full load.	Medium load.	Low load.
Revolutions per minute.....	3,481	3,545	3,583	3,602
Throttle gauge pressure ...	153	154	156	156
Vacuum	26·87	26·84	26·80	26·90
Ratio of rated load	1·26	1·02	0·77	0·42
Steam per brake h.p. hour...	13·63	13·91	14·48	16·06
Superheat, 100deg. F.				
Revolutions per minute.....	3,457	3,546	3,580	3,588
Throttle gauge pressure ...	150	156	154	153
Vacuum	27·10	27·06	27·10	27·10
Ratio of rated load	1·31	1·02	0 77	0 41
Steam per brake h.p. hour...	12·07	12 41	12·88	14·62
Superheat, 180deg.				
Revolutions per minute.....	3,477	3,542	—	—
Throttle gauge pressure ...	151	154	—	—
Vacuum	27	27·10	—	—
Ratio of rated load	1·32	1·02	—	—
Steam per brake h.p. hour...	11·17	11·45	—	—

Tests were also made to determine the variation of the speed of the turbine at different loads. This variation in the test with steam superheated to 100deg. F. was 2·5 per cent. below speed at rated load, for 31 per cent. overload, the figures for 77 per cent. load and 41 per cent. load being ·9 and 1·2 per cent. below rated speed respectively. In the test with dry steam the variations were 1·8 below normal for 20 per cent. overload; 1·60 per cent. above for 42 per cent. load, and 3·4 per cent. above for friction load. An economy of 1 per cent. for every 10deg. of superheat between the limits employed in the tests is shown by some curves contained in the report. The report calculates the thermal efficiency of the turbine tested for the several different conditions of operation. Since the thermal efficiency of a reciprocating steam-engine is usually referred to indicated horse-power, and as the tests of the turbine were in terms of brake horse-power, in order to have a common basis for comparison it was assumed that the friction of a reciprocating engine is 6 per cent. On this basis of internal steam horse-power, the thermal efficiency for dry steam is given as 17·22 per cent., for 100deg. superheat 18·43 per cent., and for 180deg. superheat 19·43 per cent.

New South Wales Electrical Association.—We have received a copy of the *Proceedings* of the above association, in which the presidential address delivered by Mr. J. R. Woodruffe-Gardam appears. This was read in Sydney on April 8. In it the practice of other presidents is followed in that a general review of electrical engineering progress is given; but the points which most interest us are those which relate to local matters. For instance, the president says that the City Council's electric lighting supply will be commenced in August or September next. It will be remembered that the Sydney municipal system will compete with those of the electric lighting companies, which already have five stations in the city with an aggregate plant capacity of 1,985 kw. The president prophesied in his address last year that the plant then being laid down by the City Council would be inadequate to meet the demands of the inhabitants. This prophesy has been justified by the demand for supply, and more plant has been ordered. The supply is offered to consumers in five different forms, and, as the president says, he will be a hard customer to please who cannot find one to suit his tastes—he may have 240 or 480 volts continuous-current, 240 or 415 volts single-phase, and 415 volts three-phase. The president laments that the voltages selected by the council for the continuous-current supply were not 230 and 460 volts, as used in Melbourne, and in the majority of cases in England, so that the confusing number of voltages for which apparatus must be stocked in the Commonwealth might have been avoided. Some amusing remarks are made on the maximum demand system of supply, and the opinion is expressed that it will not be profitable until the plant is well loaded. This shows that the Sydney authorities are well advised, and that they are not hampered by the Bermondsey clause, now on its death-bed. Amongst the comments is a quotation that the advantage of the maximum demand system is that "it is better for a customer to complain of what he does not understand than of what he does understand." Turning to the tramways, the statement is made that they are now practically all converted from steam to electric traction, only 15 miles remaining to be electrified. The increase in popularity of the system during conversion has been remarkable. In order to supply the increased amount of energy required in consequence of the larger traffic, a steam turbo-alternator set of 1,875-kw. capacity has been ordered, which will bring the total capacity of the plant at Ultimo up to nearly 10,000 kw. In another part of the address the success of electric lifts in Sydney is commented upon. The results show that with electricity at 4d. per unit, they are from 60 to 80 per cent. cheaper that hydraulic lifts, so that when energy is obtainable from the Corporation mains at 2d. per unit, as will be the case in August or September, hydraulic power will be hopelessly handicapped. The president was accorded a hearty vote of thanks for his excellent address.

Books Received.—The Gresham Publishing Company, of 34, Southampton-street, Strand, W.C., have forwarded to us vol. iii. of "Modern Electrice Practice," edited by Prof. Magnus Maclean. This, as our readers know from previous issues, is a joint production in which no less than 36 different expert authors collaborate. Thus, in the present volume there are two sections, the first deals with electric lighting and power distribution, which is again divided into five sub-sections. These are respectively, "Distribution and Transmission of Electric Energy," by W. B. Esson; "Electric Lighting and Wiring," by W. W. Lackie;

Digitized by Google

"Electric Fittings," by G. Byng and V. Zingler; "Arc Lamps," by F. Biliotti; and "Incandescent Lamps," by C. J. Robertson. The other section, No. 3, deals with electric tramways, but only contains information on "Rails," by John R. Wignall, and "Rail Bonding," by Victor Watlington. This subject will be continued in the next volume. The information contained on the distribution and transmission of electrical energy is exceedingly clear, as is to be expected from the pen of its author. It gives a large amount of information on extra high-tension transmission, which is quite new in this country. The author also goes into the cost both of generating and supply, and with the saving to be expected from the adoption of electrical power under various situations. The whole volume is quite up to the high standard set by the two previous volumes, and this publication should find its place on the bookshelf of every electrical engineer. We have received from Messrs. Charles Griffin and Co., of Exeter-street, Strand, the tenth revised edition of the "Elementary Manual on Steam and the Steam-Engine," by Prof. Andrew Jamieson. The book in its previous editions has been a great success, and the additions now made bring it up to date. Amongst these are descriptions of thermo-electric pyrometers; the latest type of steam-engine indicator; the 1902 piston and connecting rods for the London County Council tramway power station engines; the condensing plant for the Glasgow tramway power station; and the latest steam-turbines, which are now vieing with reciprocating engines for a first place as prime movers, not only for the fastest vessels, but also for large electrical generators. The *Transactions* of the American Institute of Electrical Engineers, issued in May this year, has just reached us. In this valuable discussions on various high-pressure transmission papers are contained, which discussions have been previously summarised in our columns. The American Institute continues the excellent practice of publishing papers well in advance. Thus, this volume reached us with advance copies of papers read at the Chicago Congress on the 21st and 22nd inst., three days before the commencement of that meeting. We are sure that this practice is of great assistance in promoting discussion. "Electric Motors," by H. M. Hobart. (London: Whittaker and Co. 12s. 6d.) Mr. Hobart's treatise on the theory and construction of electric motors, which we stated a few weeks ago would be characterised by considerable departure from conventional methods, has just made its appearance. We hope to deal more fully with this interesting volume in a future issue. "Electric Flashes," by A. T. M. Johnson. (London: Everett and Co. 2s. 6d.) This volume contains a highly-interesting exposition of various wireless telegraphy and telephony systems. We have received a copy of the "Special Bulletin" of the Cape Town (International) Industrial Exhibition, which commences in November. This brochure contains some instructive details relative to the commercial progress of South Africa, besides a description of the scope of the exhibition, and is excellently illustrated. By way of a souvenir of the opening of the Neepsend generating station, the Sheffield Corporation electric supply department has issued a beautifully-illustrated volume containing a complete description of the Corporation works.

The Electrical Congress.—The number of papers which have now been promised for the International Congress at St. Louis exceeds 160. Efforts are being made to secure the manuscripts of as many of the papers as possible in advance, so that copies may be printed for distribution at the congress. We have already published the programmes for Sections A, B, and C, and we now give those for Sections D and E. Of the former, which deals with power transmission, Mr. C. F. Scott is the chairman and Dr. Louis Bell is the secretary. The papers, with their authors, are as follows: "Electrical Transmission Plants in Switzerland," by Sig. E. Bignami; "Conditions Conducive to Economy in Motor Design," by H. M. Hobart; "Transmission of Alternating-Currents over Lines Possessing Capacity," by Mons. Maurice Leblanc; "Utilisation of Hydraulic Powers in Italy," by Prof. G. Mengarini; "High-Potential Long-Distance Transmission and Control," by F. G. Baum; "The Tower System of Line Construction," by F. O. Blackwell; "The Use of Aluminium as an Electrical Conductor," by H. W. Buck; "High-Tension Insulators," by V. G. Converse; "Line Construction and Insulation for High Tensions," by M. H. Gerry, jun.; "Bay Counties Transmission System," by L. M. Hancock; "Some Practical Experiences in the Operation of many Power Houses in Parallel," by R. L. Hayward; "Long Distance Power Transmission," by J. F. Kelly and A. C. Bunker; "Transmission and Distribution Problems Peculiar to the Single-Phase Railway System," by P. M. Lincoln; "The Maximum Distance to which Power can be Economically Transmitted," by R. D. Mershon; "Pioneer Work of the Telluride Power Company," by P. N. Nunn; "The High-Tension Transformer in Long-Distance Power Transmission," by J. S. Peck; "American Practice in High-Tension," by Dr. F. A. C. Perrine (representing National Electric Light Association); and "Theory of Single-Phase Motors," by Dr. C. P. Steinmetz (representing American Institution of Electrical Engineers). Section E, which deals with electric light and distribution, will be presided over by Mr. J. W. Lieb, jun., the secretary being Mr. G. S. Dunn. The papers and authors are as follows: "Impregnated Arc Light Carbons," by Prof. André Blondel; "Single-Phase Motors," by Herr Max Déri; "Rates for Electricity Supply," by Herr E. de Fodor; "Insulating Materials in High-Tension Cables," by Sig. Ing. E. Jona; "Upon a Means for Compensating the Series Connection of Induction Motors," by Prof. W. Kübler; "Storage Batteries," by Herr Karl Roderbourg; "Commercial Limits of Electric Transmission, with Special Reference to Lighting Service," by Sig. Ing. Guido Semenza; "The Superiority of the Alternating Current for Distribution in Large Cities," by Dr. G. Stern; "Measurements of the Energy of Light and Heat Radiation from Electric Light Sources," by Dr. W. Wedding; "Recent Improvements in Electrolytic Meters," by Arthur Wright; "The Testing of Alternating-Current Generators," by B. A. Behrend; "Protection and Control of Large Light-Tension Distribution Systems," by George Eastman (representing Nat. Elec. Light Assoc.); "Rotary Converters and Motor-Generators in Connection with the Transformation of High-Tension Alternating to Low-Tension Street Current," by W. C. L. Eglin (representing Assoc. Edison Illum. Cos.); "The Effect of Steam-Turbines on Central Station Practice," by W. L. R. Emmet; "Underground Electrical Construction," by Louis A. Ferguson (representing Assoc. Edison Illum. Cos.); "Storage Batteries as an Adjunct to Central Station Equipment," by Gerhard Goettling (representing Assoc. Edison Illum. Cos.); "American Meter Practice," by G. Ross Green (representing Nat. Elec. Light Assoc.); "Metering Efficiency on Customers' Premises," by Caryl D. Haskins; "Steam-Turbines," by Francis Hodgkinson; "Incandescent Lamps," by John W. Howell; "Distributing Systems from the Standpoint of Theory and Practice," by Philip Torchio; and "The Selection of a Distributing System for a Large City," by W. F. White. The subject to be dealt with by Prof. S P. Thompson will be announced later.

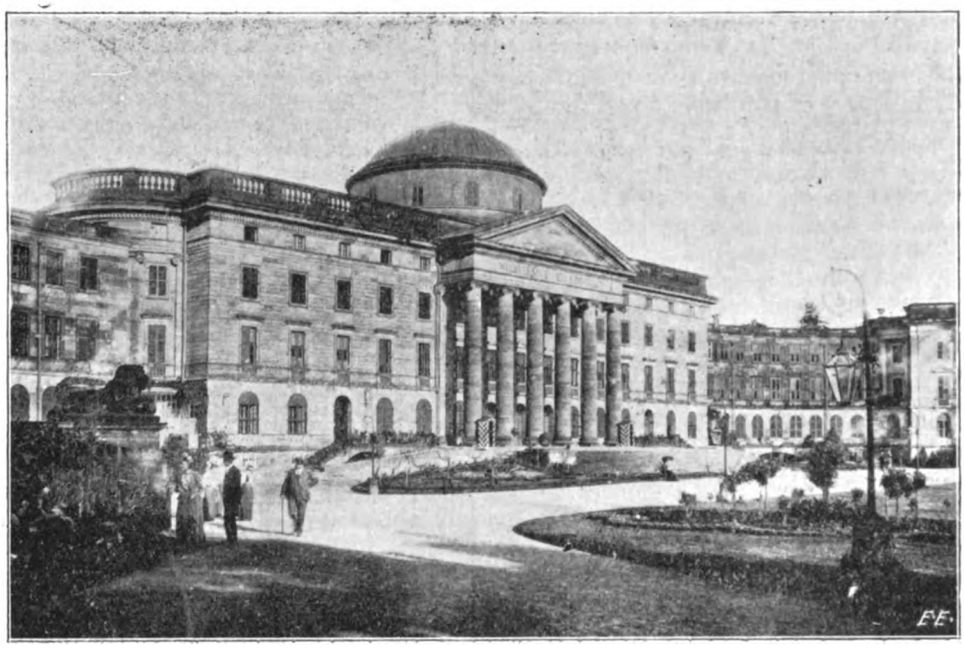
THE VERBAND DEUTSCHER ELEKTROTECHNIKER.

Twelfth Annual Meeting. — Cassel.

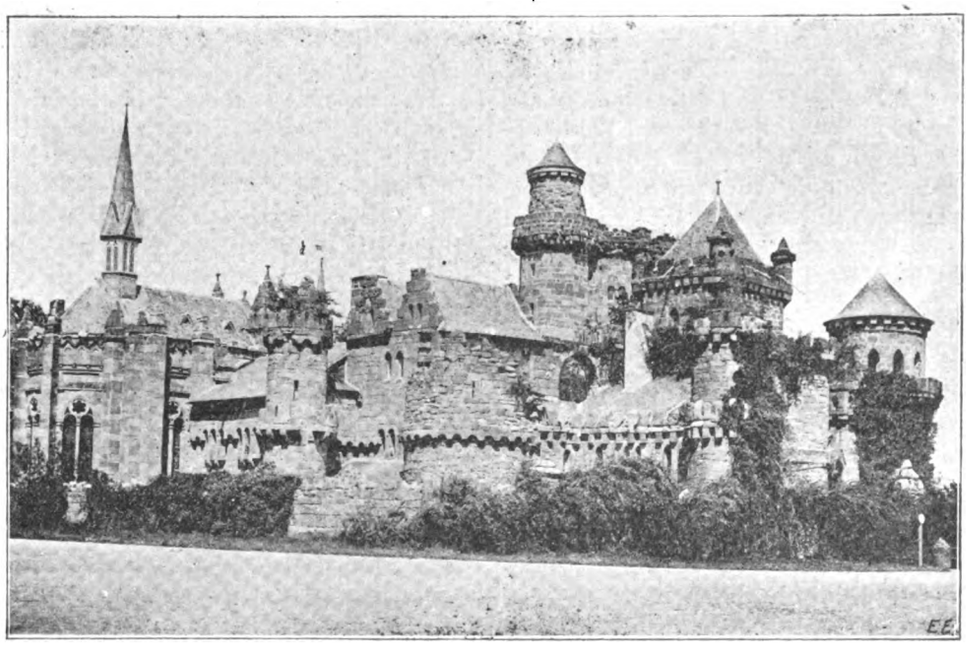
[FROM OUR SPECIAL CORRESPONDENT.]

Providence seems to have marked the annual meeting of the Verband Deutscher Elektrotechniker for special favour. Certainly not within my recollection has there occurred aught to prove the contrary, and having made common lot with the Verband at such times for years past, I may claim to speak with some authority. It is now my pleasure to record the success of the Cassel meeting, which commenced on Thursday, June 23, and was concluded on the following Sunday.

Cassel is a midland town, possessing some 100,000 inhabitants. It is situated on the Fulda—a tributary of the better-known Weser—being the southernmost point open to navigation by ships from Bremen. Further, it is a junction point for no less than six railway lines. I cannot claim an intimate acquaintance with the town itself, not having visited it prior to the occasion in question. Like in most German towns, the contrast between the old and modern parts is very striking. Some of the houses by the river struck me as being especially quaint, and the streets narrow and tortuous, while recent extensions, on the other hand, pay tribute to German progress in municipal organisation. For its size Cassel is rich in works of art and antiquities, some notable collections being contained in its several galleries and museums. Moreover, it enjoys close proximity to the Royal Palace, Wilhelmshöhe, being, for that reason, what is locally termed a Königliche Residenzstadt, a distinction, it is true, not at all uncommon in Germany. Of some historical interest is the fact that Napoleon III. was held prisoner in the palace from Sept. 5, 1870, to March 19, 1871. Far more noteworthy, however, than the palace itself are its unique surroundings. A fantastic building surmounted with a gigantic statue of Hercules stands at a commanding elevation in the background. Cascades from the front of this building to the lower level make the whole an imposing spectacle. Besides these cascades Wilhelmshöhe can boast some magnificent waterfalls, in whose development art has assisted nature. The beauty of the waterfalls and general charm of the park surrounding the palace defy adequate description. Suffice it to say that the present development of the estate dates from its possession by Landgrafen Karl, 1670-1730. A visit to Wilhelmshöhe and the associated attractions was, of course,



Royal Palace, Wilhelmshohe.



Lowenburg, Wilhelmshohe.

Digitized by Google

included in the programme arranged for the meeting. The Germans are adepts at combining business with pleasure without detracting from either. But since I have so often dwelt upon their methods of distraction, details of this visit may well be omitted here, as also of the "Begrüszung der Festteilnehmer" on the opening day, and the "Gartenfest im Wilhelmshöhe" on Saturday evening.

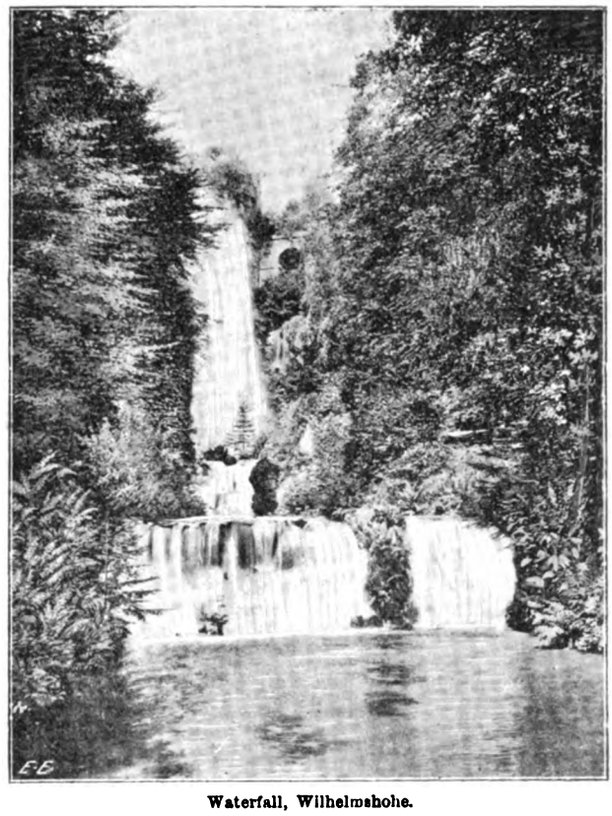
Business proper was commenced on Friday morning, but having regard to the central situation of Cassel the meeting was, perhaps, not so large as might have been expected, under 200 members reporting themselves. The President, Herr Geh. Baurat Dr. Ulbricht, of Dresden, opened the proceedings with a brief address. Assurance of the hearty welcome of the meeting in Cassel having been expressed by the Government deputy, Se Exzellenz Herr Ober präsident von Windheim, Herr Oberbürgermeister Müller, and others, Mr. Gisbert Kapp, in his capacity of general secretary to the Verband, then presented his annual report, which was of unusual length and interest, mentioning among other things that the committee entrusted with the question of standardising system and voltage on board ship had carried out the wishes of the Verband in regard to consulting with the English Engineer-

Cascades, Wilhelmshohe.

ing Standards Committee, with a view to obtaining uniform practice. As deputed by their committee, he (Mr. Kapp) had attended a meeting of the English committee and submitted their proposals. He found English engineers, representing commercial interests, were ready to adopt these proposals, but the Royal Navy Department had decided, for the present, to adhere to the direct-current system of generation at 100 volts (against the Verband's proposal of 110 volts), and possibly later to adopt a pressure of 220 or 230 volts. German experts on the installation of electrical plant on board ship regarded the higher voltages as dangerous; but as the Royal Navy did not contemplate any immediate change they were concerned for the time being, at any rate, with only the two pressures—viz., 100 volts and 110 volts. Their committee had decided in favour of the latter, and a motion to adopt this pressure as the standard for ship installations would be submitted to the meeting by Herr Schulthes.

The committee on hysterisis had given their attention to the question of ageing, which at one time excited so much concern in scientific circles. He thought, however, that the meeting would be convinced by the report to be presented by the chairman of the committee that the method now adopted in manufacturing iron plates for electrical purposes left no cause for further anxiety on this account. The question of the systematic inspection of electrical installations was discussed at a council meeting of the Verband in Kiel so far back as 1900, the view then obtaining being that it lay in the interests of the German electrical industry to establish such control as would ensure the general observance of the practice prescribed by the Verband. At that time, however, the Government were not forthcoming with any definite proposals, and the discussion was of a purely academic character. But the question had been invested with fresh importance by the introduction of a Government Bill dealing with the cost of testing and supervising electrical installations. The council had therefore deputed the chairman of the Safety Rules Committee and himself (Mr. Kapp) to submit a petition to the XII. Committee of the Abgeordnetenhauses, in which petition it was requested that (1) the Safety Rules should be adopted as basis for the proposed supervision, and (2) that the supervision itself should not be by police officials, but by practical electrical engineers.

The Council had requested him (Mr. Kapp) to obtain statistics relating to accidents through electricity. Applications had been made to 16 unions and 35 firms for full



Waterfall, Wilhelmshohe.

information concerning any accidents through electricity which had come to their knowledge. The purpose of these enquiries was, in the first place, to ascertain what alterations, if any, could be made in the Safety Rules, so as to ensure better protection to persons. So far only 13 replies had been received, so that the statistics were far from being complete. Nevertheless, the figures obtained justified the conclusion that in comparison with the enormous use of electrical energy for power purposes in Germany, the number of accidents was extremely low. The 13 reports gave particulars of 45 cases of personal injury in all, dating from 1892 to the present time. Of these cases 9 were fatal, 12 resulted in serious injuries, while about half (24) were slight. In five instances the cause was attributed to faulty installation, the injured workmen's own negligence being given in regard to the majority. From the official statistics for Westphalia, placed at the disposal of the Verband by Prof. Dr. Rasch, it appeared that between 1895 and 1900 the cases of personal injuries directly attributable to electricity were as follows: slight injuries, 25; serious injuries, 5; killed, 23—total, 53. Defective installation was given as the cause in 10 instances.

Some doubt had been raised in medical circles as to the suitableness of the directions published by the Verband

Digitized by Google

some five years ago for first aid in the case of electric shock. The Council had consequently decided to entrust some members of the medical profession with the examination of these directions with the object in view of determining whether they still satisfied requirements in the light of present knowledge, and if not, what alterations should be introduced.

The report incidentally stated that the membership of the Verband had increased by 163 members during the past year, numbering now a total of 3,521, while the finances were in an equally healthy condition; also that the official organ of the Verband—*i.e.*, the *Elektrotechnische Zeitschrift*, had a weekly circulation of 8,400 copies at the end of 1903.

I have purposely omitted to mention some portions of Mr. Kapp's interesting report, since it is my intention to deal in greater detail with certain of the items mentioned later on. Enough has already been said, however, to indicate the thoroughness with which the Verband are pursuing their policy in the general interest of the electrical industry in Germany.

STANDARDS FOR THE USE OF ELECTRICITY ON SHIPS.

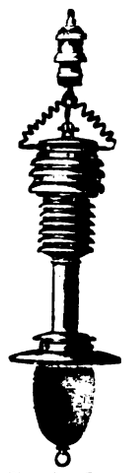
In due course Herr Schulthes submitted the proposals regarding the use of electricity on ships, which had been referred to by Mr. Kapp in his report. The chief recommendation, as already explained, was to adopt direct current at a line pressure of 110 volts as the standard for use on shipboard, while at the same time employing the two-wire system of distribution. Several pertinent reasons had guided the committee in their choice of direct current. Direct-current motors were at present the most suitable for use on board ships by reason of the better control which they enabled as compared with other types. In regard to danger from shocks, direct current was less to be feared than alternating current of the same effective potential. The navy was already dependent on direct current for its search-lights. A uniform system for warships and the mercantile marine was not only in the interest of navigation, but also in that of the electrical industry. The distributing cables for polyphase currents, which at present only came into question for power purposes, were less accessible to inspection, and since the three conductors must be made into a cable in order to reduce the self-induction, it became a difficult matter to lay it to large motors due to its section. Moreover, branch circuits were difficult to connect. The demand for electricity in the mercantile marine was principally for lighting. The advantages hitherto claimed for alternating current in that the compass was not affected thereby had little weight, since this trouble could be avoided with direct current by giving proper attention to the laying of the cables and to the construction and erection of the motors.

As regarded the adoption of 110 volts, this pressure was also usual on land, lamps, motors, and apparatus for this tension being, therefore, available. Moreover, this voltage represented a value up to which experience had shown it was safe to go without hesitation, bearing in mind the difficulty of efficiently insulating conductors on board ships.

It remains to add in connection with these standards that the recommendations of the committee were unanimously approved by the meeting.

EXHIBITION OF NOVELTIES.

An exhibition of electrical novelties is generally to be found within the immediate neighbourhood of the Verband's place of meeting. This occasion proved no exception to the rule, although the number of exhibits was far less than usual. Deserving of special mention is the Siva arc lamp, which may be described as the midget of midgets. A feature of the lamp which is likely to greatly assist its sale consists in that it is made to connect to a lamp holder of the Edison screw pattern such as is used in Germany. For that matter there is no reason why it should not be adapted equally well for attaching to a bayonet socket holder. The lamp is made for direct current in two sizes. The lesser of these consumes one ampere at 110 volts, while yielding a mean hemispherical candle-power of 150; it will burn 10 hours. On the other hand, the larger size takes 3½ amperes at 110 volts, yielding a mean hemispherical candle-power of 600, and burning 20 hours. The line resistance is enclosed in the lamp, the hood of which is corrugated (as shown in the accompanying illustration), so as to radiate the heat generated. Another advantage of the lamp is that there need be no waste of carbon, since the remnant of the upper carbon can be used up in the lower holder. Four lamps were on view, two of each size. They were giving a beautiful white light, and burning with great steadiness. I understood the lamps were recently exhibited in Berlin, where orders for over 300 were quickly taken. In Cassel, orders for about 50 lamps had been secured up to the time of my visit. Apart from the convenience which it offers for fixing the price of this lamp is all in its favour, being in the case of the smaller size £1 and in that of the larger size £1. 10s.



Siva Arc Lamp.

The makers are Messrs. Ehrick and Graetz, Berlin So. 36. Among the other exhibits I noticed one by the well-known firm of Mix and Genest, which included some lever switches with porcelain bases and handles. They looked very nice and clean mounted on a switchboard, and no doubt possessed very high insulation resistance, but what about mechanical strength? It had never occurred to me that porcelain was a suitable material for a switch lever, and I still have my doubts upon the point despite its application for the purpose in this case.

(To be continued.)

LIFE OF INCANDESCENT LAMPS.

BY C. A. B. GARRETT.

The curves given in this paper were obtained recently in a series of tests of incandescent lamps under ordinary working conditions in the Electrical Laboratory, University College, Nottingham. The results obtained, though not entirely new, were so striking as to appear to deserve attention. Eight lamps in all were used, two being selected from each of four well-known makers. These were joined up on a base-board connected to the ordinary Corporation lighting mains. They were then run night and day continuously, and the maximum candle-power measured at a fixed hour every day by means of a photometer. All the lamps were thus compared every day with a separate incandescent lamp (Standard A). Now, the absolute candle-power of a lamp depends on the pressure at which the lamp is being run; but it was found at first by a separate series of experiments on all the lamps that the fractional variation in candle-power due to change in pressure, within the limits of the experiments, was the same for these lamps. Then, since the lamp under test is on the same circuit and at the same pressure as Standard A, its candle-power relative to A can be determined. Standard A was compared occasionally with a second Standard B, kept for reference. Finally, the absolute candle-power was found by comparison with a pentane standard lamp.

The pressure of 209 volts, which seemed to fairly represent the average pressure of the supply, was taken as standard; the real pressure was constantly varying, but we waited until it came to 209 volts before any readings of current were taken. The current taken by each lamp was measured every day. Thus, at any time, we know

Digitized by Google

the power absorbed by every lamp, and the amount of illumination given by it. As the lamps were made for 200-volt circuits, it is obvious that they were very greatly over-run, yet it is an interesting fact that not one of the eight lamps was "burnt out" whilst running 1,500 hours, after which no further measurements were taken. The lamps of the different makers, nominally of the same candle-power, did not agree with each other, but those of the same maker agreed much more closely. This justifies us in taking a mean of the two lamps in each case as representing a given make of lamp.

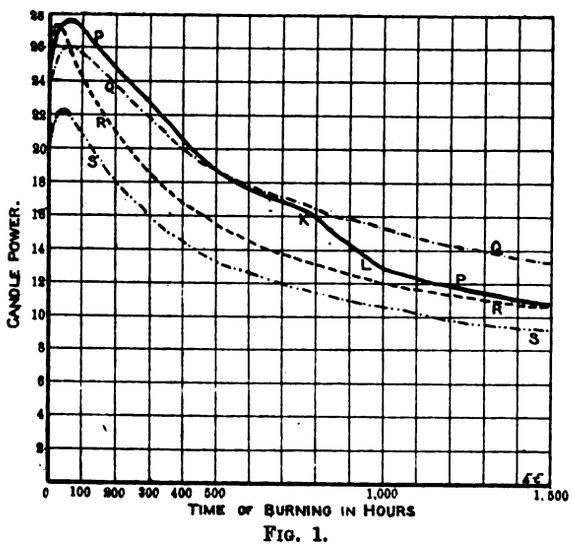


FIG. 1.

The curves given in Fig. 1 show how the candle-power of the lamps changes with time. The curve represents the mean of the two lamps in each case. Nominally, they were all 16 c.p. when run at 200 volts. It will be seen that at first they gave at 209 volts values of candle-power ranging from 20 c.p. to 24 c.p. Then we have a rapid rise in candle-power in every case during a period varying from 20 to 50 hours, when the maximum is passed, and a rapid fall sets in. This continues for 300 or 400 hours, and afterwards the fall becomes more gradual, though still fairly rapid. At the point K in curve P_1, after 750 hours, a

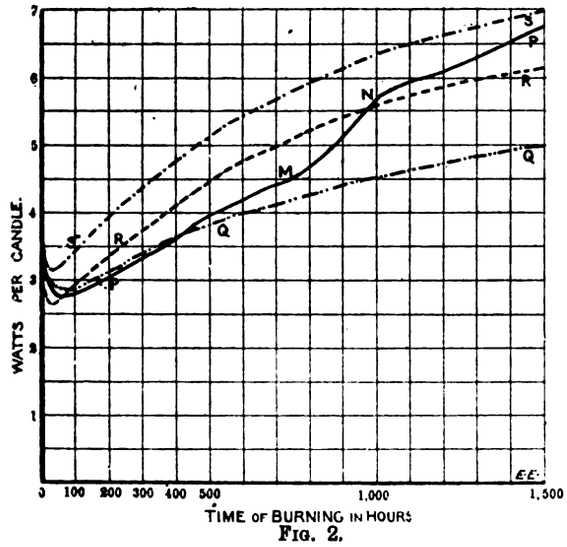

FIG. 2.

sudden change took place in one of the lamps; its candle-power fell to a much smaller value, though it continued to burn to the end. It might have been thought that the lamps of lower candle-power had been made specially to stand more than 200 volts, and consequently would not fall so rapidly as the others. This at first sight seems to be correct, as the curves get closer together as time goes on. On further examination, however, this is not confirmed; for instance, take the ratio of the ordinates of Q + S at 100 hours and 1,500 hours, they are 1·27 and 1·44 respectively, so that Q has increased its superiority over S, instead of decreasing.

This is shown more clearly in Fig. 2. The ordinates give the inverse of efficiency, for they show the power required for a given light. The rapid rise in candle-power during the first 20-50 hours, shown in Fig. 1, accounts for the first part of the curve, the efficiency gets better—*i.e.*, the power absorbed per candle decreases. The part K L of P_1 (Fig. 1) is easily recognised at M N, a sudden rise in power absorbed per candle. Although the power absorbed by any lamp decreases continuously as time goes on (owing to the increase in resistance of the lamp) the rapid diminution in candle-power more than makes up for this,

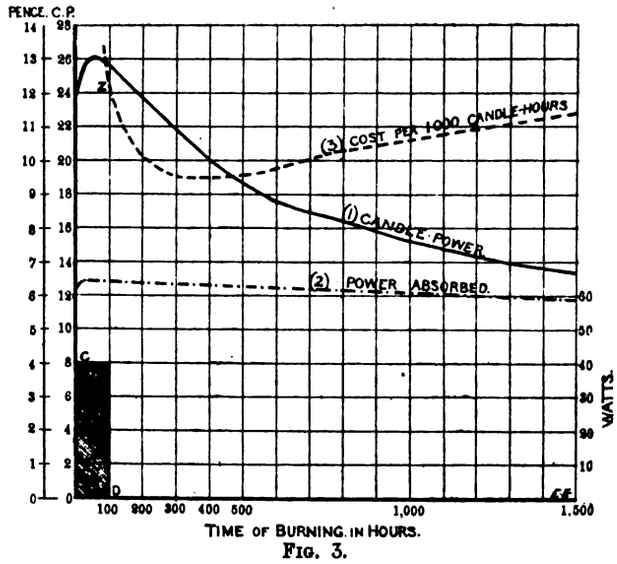

FIG. 3.

and, whereas the lamp at first takes three watts per candle, after 1,500 hours it takes six watts per candle. The superior lasting powers of the Q lamp are very plainly shown on the diagram, confirming the facts deduced from Fig. 1.

Fig. 3 contains three curves, all referring to the Q lamp. The first is the candle-power curve of Fig. 1, from this we can obtain the number of candle-hours obtained by running the lamp t hours. This is given by the area enclosed between axes of co-ordinates, the curve, and the ordinate at $x = t$. The second curve gives power absorbed by the lamp at any time; a similar area on this curve gives the total cost of power used in the given time; if we add to this an area, C D (shaded), representing the cost of the lamp, we have the whole cost of lighting. Finally, dividing the whole cost for time, t, by the number of candle hours obtained, we get the cost per candle-hour of the light which has been obtained. By calculating this for all values of t, we construct the third curve of Fig. 3. In order to understand the meaning of this curve, take as an example the point Z (100 hours, 1s. 0¼d.). This means that if we discard

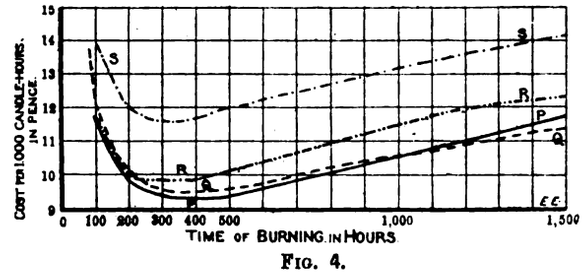

FIG. 4.

each lamp after burning 100 hours and replace it by a new one, every 1,000 candle-hours costs us 1s. 0¼d. The curve has a minimum at 400 hours, showing that if we wish to work most efficiently we must replace each lamp after burning 400 hours. If, on the other hand, as observed by Prof. Fleming, we can do with less light, it is obviously *cheaper* to burn the lamp until it breaks, both on account of the cost of a new lamp, and also of the fact that an old lamp uses less power than a new one. Several experimenters have recommended that the lamps be discarded when their candle-power has fallen to 70 per cent. of the original value. In the case considered here, to secure maximum efficiency we discard the

Digitized by Google

lamp after 400 hours, at which stage the candle-power has fallen to 77 per cent. of the maximum value attained.

Hitherto, in practice, the cheaper plan seems to have been generally adopted, burning the lamp either until it breaks or until the candle-power has fallen very low. Note that in these tests, after 1,500 hours burning, the candle-power has fallen off to 50 per cent. of the maximum value, though the lamps did not appear to be seriously blackened. Curve 3 of Fig. 3 is repeated in Fig. 4, together with similar curves for the other lamps. P + Q lamps run very close, P being a little better if the lamps are discarded early, while Q shows better lasting qualities.

INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

Ninth Annual Convention.

This convention at Derby was opened on Wednesday last by the Mayor (Councillor C. Boam), who extended a hearty welcome to the members. He said the association had honoured Derby by electing Mr. Wilmshurst as its president. They respected him highly in Derby, and were gratified to find that his fellow members did so also.

Alderman BUTTERWORTH, the chairman of the Electric Light Committee, also welcomed the association, and referred to the hospitality which had been extended by the adjoining towns of Nottingham and Sheffield.

Mr. WILMHURST, on behalf of the Municipal Electrical Association, thanked the two speakers for their kind words. He then read the following address:

Presidential Address.

BY T. P. WILMSHURST, BOROUGH ELECTRICAL ENGINEER, DERBY.

At the commencement of our ninth annual convention it is with great pleasure that I am able to congratulate you on the continued growth in numbers and importance of our association. When our first president, Mr. Arthur Wright, addressed you, he referred to the fact that our members controlled undertakings with a capital outlay amounting to £4,000,000. Within eight short years this has risen to £25,000,000, and, including the tramway undertakings with which many of us are connected, it may be safely said that our members control an industry with a capital of nearly £40,000,000.

Before going further, however, I must refer to the grievous loss which we, and, in fact, the whole profession, sustained by the sudden death at an early age of Mr. Quin. For several years he served on our Council; his opinions always commanded respect, and his abilities were such that all who knew him prophesied for him a brilliant career.

When reviewing the influences which affect for good or evil the undertakings we control, the attitude of Parliament and parliamentary committees cannot fail to have a great interest for us, since anything tending to unreasonable restriction cannot fail to have an adverse influence on our prospects. One cannot, therefore, view without a certain amount of uneasiness the want of continuity of policy in parliamentary committees. I will give you one or two instances. The Committee of the House of Commons which sat in 1900, under the chairmanship of Sir James Kitson, to consider the question of power schemes generally, laid down the following principle: "A local authority which undertakes and is prepared to give a full and ample supply of electrical energy for all purposes to consumers within its district ought not, without its consent, to be required to give facilities for the supply within its district of electrical energy by other undertakers. But if a local authority is unable or unwilling to provide on reasonable terms and within a reasonable time a full and adequate supply of electrical energy for any purpose to any company or person applying for same within its district, such company or person should be at liberty after notice to the local authority to obtain their supply from other authorised undertakers, and the local authority should be required to give all necessary facilities for this purpose." In other words, peaceable possession was to be given in return for good behaviour. This principle was adopted, and in consequence all important towns having electric supplies were excluded from the many power schemes which were promoted during the next two or three years. It was therefore a considerable surprise to us when another parliamentary committee reversed this principle and allowed the city of Bristol to be included within the area of a power company. In this case at any rate there was no question of an inadequate or defective supply being furnished by the Bristol Corporation; in fact considerable expense had been incurred in providing special arrangements for the supply of electric power for local industries.

Another instance is the insertion in a Bill of the famous—or infamous—Bermondsey clause, which might have been invented with the object of strangling an industry in its early days, while in other Bills the clause has been refused; allied to this is the Willesden clause, which will be fresh in the minds of many of you. Yet another instance is the electrolysis clause which has been inserted in a number of tramway Bills, while in other cases we have been refused this clause, but instead have been told to comfort ourselves with the assurance that we are amply protected by the existing Board of Trade regulations. The recent decision of a parliamentary committee to grant to a company powers to run over the lines of the Newcastle Corporation tramways is a new departure, which if confirmed by parliament will have far-reaching results. Another novel decision recently given is the case of a certain corporation, which in promoting an Omnibus Bill sought and obtained power to give a supply of electricity to a number of villages within its sphere of influence with the consent of the local authorities controlling this village. The proviso was inserted, however, that the consent of the corporation should not be required in the event of a certain power company also wishing to supply these villages.

I have said enough to show how injurious to us may be the effect of this unfortunate want of continuity of policy. We often hear the complaint that Parliament is overloaded with minor details, and that the consideration of purely local matters could better be left to certain decentralised bodies to deal with. A little consideration shows that this would prove an aggravation of rather than a panacea for our troubles. Obviously these troubles arise from the fact that similar questions involving the same principles are dealt with by several different parliamentary committees, the members of which may hold widely divergent views on such questions as municipal trading. The only remedy that I can see is to delegate matters involving the same questions of principle to one committee or to a body of commissioners similar to that which adjudicates on light railway schemes, or by conferring wider powers on the Board of Trade.

We have been accused in some quarters and occasionally in the technical Press of looking on the power companies as our natural enemies. This view is entirely wrong, and somewhat unjust to us as engineers. We all recognise that power companies have a distinct sphere of utility in supplying the large and small industries outside the reach of the local municipal or company supply, and in giving the benefits of an electric supply to small towns which hesitate to lay down their own plant. I do not say for a moment that we welcome their competition in

Digitized by Google

our towns—if we did we should probably not be believed—but what we most strongly object to is their attempting to obtain terms and exemptions which we are denied under the Electric Lighting Acts and our provisional orders. For instance, Section 19 of the Electric Lighting Act, 1882, provides that the undertaker shall supply anyone who demands a supply, subject only to certain very limited safeguards; the power companies are, however (or seek to to be), relieved of this obligation. In other words, while we are compelled to take the rough with the smooth, the power companies seek only the plums. Again, in a number of power schemes which I have had occasion to examine within the last few years, the promoters have made comparisons of the cost to the consumer under their scheme with the cost of the municipal supply, invariably to the disadvantage of the latter. Cross-examination, however, has usually brought out the fact that while the municipal supply is given at a pressure suitable for immediate use, in the rival scheme it is proposed to give the consumer a supply at 5,000 to 10,000 volts, leaving on him the onus of providing his reducing and converting machinery. This comparison is as unfair as a comparison of the cost per ton of a finished article with that of the raw material from which it was made.

The growth of our business, as shown in the periodical returns which are available, is very satisfactory. It is advisable, however, to remember the great progress which is also being made by our competitors. In recent years the gas business has received an enormous impetus from the introduction of the Welsbach mantle, and it would be folly on our part to disregard their experience. Rather let us see if the methods they adopt cannot also be adopted with benefit to ourselves. When the old flat-flame burner was in general use the burner was of the simplest possible character and if kept clean would last an indefinite time without attention. The old order, however, changed with the extended use of the Welsbach mantle. This gradually deteriorates with use, and has to be replaced at more or less frequent intervals. Neglect of this results in discredit being thrown on the supply. Gas engineers have not been slow to see that for the credit of their undertakings some sort of supervision of the consumers' fittings is to the interest of both buyer and seller. We find, therefore, an increasing tendency for arrangements to be made whereby, for a small payment, a periodical inspection is given.

Now, the position of the incandescent electric lamp is analogous to that of the mantle. It is a device requiring technical knowledge in its selection, so that lamps of reasonably high efficiency and long life may be used. Yet how many of our consumers consider life and efficiency before first cost when purchasing? The result is, inefficient lamps are used and are allowed to burn beyond the "scrapping point," and heavy bills follow; the supply is blamed as "not being so good as it used to be," and strained relations arise between our consumers and ourselves. I believe, therefore, that if we wish to continue and increase our rate of progress, the following suggestions are worthy of consideration: (1) the periodical renewal of consumers' lamps free or on easy terms; (2) the periodical inspection of consumers' lamps *in situ*; or (3) the free testing of and reporting on consumers' lamps. I am aware there are deeply rooted objections to the first two courses. Many engineers (and their consumers) shrink from organised domiciliary visits and from interference of any sort beyond the meter. Another objection often urged is that we do not purvey light, but electrical energy, and consequently it is no concern of ours how that energy is used.

Though I have no sympathy with the principle of the municipality undertaking wiring or interfering with the legitimate business of the local contractor, I believe that only good can result from our selling lamps of good efficiency at the lowest possible price. The opponents of municipal trading will, I think, admit that this is germane to the business of electricity supply, and Parliament has recognised this by permitting in many local Acts the clause authorising us to "sell, let on hire, and otherwise deal with electric lamps, etc." Personally, I am strongly in favour of the policy of testing free of charge all lamps which the consumer likes to send us: the expense to us is very small and there should be no difficulty in arranging for the tests to be carried out during the night shift or some other convenient time.

We are handicapped in the pushing of our business by the fact that our capital charges are so heavy as compared with our revenue. This is, I believe, largely due to the want of a cheaper and more efficient method of storage. As a matter of fact, the average percentage of our revenue to capital only amounts to 10 per cent., as compared with 24 per cent. of gas undertakings. It is a sign of promise for the future, however, that the increasing use of power during the hours of daylight is helping towards the solution of the problem of this small percentage. This, however, should be sold at the lowest possible price, and, if necessary, encouraged by letting out the motors on hire. The progress of power supply in many of our towns is so marked that I believe it is having, and will have, a distinct influence in those towns which wish to retain old and attract new industries. Just as in foreign countries we find new and thriving trades settling round the sources of cheap water power, so I believe the best industrial inducement we can offer to the manufacturers to settle within our boundaries will be the offer of cheap electric power. In our own town of Derby the progress of power supply has been most encouraging. Five years ago we gave a supply to 20 motors aggregating 70 kw. At the present time we have a total of 250 motors aggregating 1,300 kw. connected to our single-phase mains, while the percentage of units sold for power to total units sold amounts to 30 per cent.

Allied to the foregoing is the vexed question of the proper apportionment of charges for energy for tramways between the two committees interested. Many members of tramways committees who have usually not had the opportunity of studying the considerations which underlie the costs of production, fail to see why they should be asked to pay say 1½d. to 2d. per unit, while smaller consumers of energy for industrial purposes only pay say 1d. to 1½d. per unit. A little consideration shows that there are at least two good reasons why this is so. The cost of producing electrical energy is independent of the purpose to which that energy is applied, and it depends chiefly on the rate of production; in other words, on the load factor. Now, experience shows, contrary, perhaps, to what one would expect, that, as a rule, a motor load has a higher load factor than a tramway load; quite frequently it is 10 to 15 per cent. higher, owing partly to the fact that the traction plant running has to be larger than the actual load.

The second consideration is that in the case of the traction supply the energy must be taken from a separate plant to that supplying the lighting, and also a separate and distinct switchgear and set of mains must be provided, whereas the motor load is taken from the same machinery and mains as is supplying the lighting. For towns of moderate size I look to the battery and reversible booster as an important factor in reducing tramway costs. I do not, however, wish to trench further on the question, as you will have on Friday an opportunity of fully discussing it.

In our endeavour to improve our costs of production I often think that we do not sufficiently consider the importance of the item, "rent, rates, and taxes." From the fact that we have no hand in fixing the amount of our assessments, we are rather apt to dismiss the question of these charges as being unimportant, or, at any rate, as a burden to be borne with resignation, and as engineers we often know very little of the methods on which our assessment is based. I think this question of the equitable assessment of electricity works is one which our association might profitably take up in the near future. To illustrate its importance, I need only say that reference to the columns of the *Electrical Times* shows that in five towns the rating is heavier than the coal bill, while in 20 towns it is over half the amount of the coal bill. It is only natural that in those towns where the rating of the works is low the engineer does not look too closely into whether the basis of his assessment is equitable, provided the amount of money which he has to contribute is reasonable.

There is a somewhat extraordinary divergence of practice in the methods adopted by the various rating authorities.

Digitized by Google

In some towns it depends solely on the caprice of the assessment expert; in some an amount is arbitrarily fixed for a few years until it is seen what development takes place; in others it is based on the capital expended, while in others again it is based on the total horse-power installed. The result of such discordance is that this item in our cost-sheets varies from ·02d. per unit sold in one town to ·7d. in another, and this can hardly be due to variation to this extent in the amount of the rates. The generally recognised custom seems to be to treat the undertakers as an "hypothetical tenant," deducting the working expenses from the gross receipts and making certain allowances for stock in hand, working capital, and depreciation. As to whether this is the fairest method I fear I am not competent to express an opinion, but if we could bring about greater uniformity in this matter, and so help some of our undertakings who are groaning under unduly heavy rating burdens, we should be worthily fulfilling one of the primary objects for which our association was formed.

In conclusion, I would make an earnest appeal to all our members to do what in them lies to support the work of the Engineering Standards Committees. By more rigid adherence to standard designs and by judicious stifling of that natural desire for originality which smoulders in the breast of every well-regulated engineer, we shall be making an important step in the reduction of our capital expenditure. I fear you will have found this address somewhat tedious by comparison with those of my predecessors in the chair, but I feel that the points alluded to are of some importance to us in the conduct of our concerns. I am glad to think that the papers to be read at this convention are of an eminently practical character, and I venture to hope that your visit to the Midlands will not be without profit and pleasure to you all.

A cordial vote of thanks, proposed by Dr. PANTON (of Bolton) and seconded by Alderman PEARSON (of Bristol), was given to the president. The seconder quite agreed with the remarks as to the vacillating decisions obtained from parliamentary committees. He thought that the results of spinning a coin by the two leading barristers would give about equal justice as the decision arrived at by the parliamentary committee after a fortnight's work.

The following paper was then read:

Commercial Practicability of Electric Traction by Surface Contacts.

BY C. E. C. SHAWFIELD, A.M.I.E.E., M.I.MECH.E, BOROUGH ELECTRICAL AND TRAMWAY ENGINEER, WOLVERHAMPTON.

Many municipalities contemplating the adoption of electric traction are making enquiries into the merits of that most abused of all methods of electric traction—namely, the surface-contact system. As the author has had charge during the past 2½ years of the only surface-contact system of electric traction in commercial operation in Great Britain, he has ventured to place some of his experiences and the conclusions he has deduced therefrom on record, in the hope that they may be of interest to the members of this association, and that they may give rise to an interesting discussion. It is not the intention of the author to discuss in this paper the respective merits or demerits of the various contact systems now on the market, but rather to make certain comparisons between the overhead system, which is so universally adopted in this country, and the surface-contact system which has been under the control of the author at Wolverhampton. The surface-contact system in operation at Wolverhampton was first introduced into England by the Lorain Steel Company of America, who had previously experimented with the system at Washington. It was first brought before the notice of the Wolverhampton Tramways Committee in March, 1901, and after lengthy negotiations a contract was entered into between the Corporation and the Lorain Steel Company by which the latter were to equip about 11½ miles of single track with their surface-contact system, and allow the Corporation to operate the lines so equipped for a period of 12 months. It was a condition of the contract that if the system proved itself a commercial success during the period of experimental operation, the Corporation were to take over and pay for the same at an agreed upon rate, but if it failed to prove itself safe and reliable and commercially successful, the Lorain Steel Company were to remove their apparatus and bear the whole cost of the experiment. The 12 months' experimental operation terminated on April 17, 1903, and although there was a great deal of difference of opinion in the Town Council as to the advisability of retaining the system, it was eventually decided on Sept. 11, by a large majority, that the system should be accepted. Shortly afterwards it was decided to proceed with the reconstruction of existing routes operated by horse traction and the construction of new routes, amounting in all to an additional seven miles of single track, and the Council decided that these extensions should also be equipped with the Lorain surface-contact system. About five miles of these extensions have already been completed, and it is expected that the remainder will be finished very shortly. The design and general arrangement of the Lorain surface-contact system has already been fully described and illustrated in the technical Press, and is probably well known to the majority of the members of this association, and therefore the author does not propose in his paper to give any technical description of the system itself, but hopes to have samples of the various parts and large scale drawings at the meeting for the inspection of members, and for the better illustration of certain points raised in this paper. In comparing the respective merits of the overhead system and the surface-contact system, the author proposes to do so from the following standpoints—namely: (1) safety to human beings and animals; (2) reliability of operation; (3) cost of operation and maintenance; (4) cost of installation; (5) disfigurement of streets and obstruction to traffic.

SAFETY.

In any electrical or mechanical system, probably the most important point to be considered is the safety of the general public, and it is doubtless the appreciation of this fact that has led the legislature to impose stringent regulations and conditions upon the use of electricity for the purpose of tramway operation. In comparing the respective advantages from the point of view of safety of the overhead system and the surface-contact system, it is evident that only one source of danger need be seriously considered—namely, that of electric shock—as practically all other risks are common to all systems of electric traction. In the case of surface-contact systems it is evident that the only portion of the apparatus exposed to the public from which a shock could, under any possible conditions, be obtained is the metal stud in the centre of the track, and that this can only become or remain alive (except when it is covered by a car) in the event of some failure of, or defect in, or damage to the mechanism which operates it. The actual value of this risk may best be estimated in the light of actual experience, and the author has therefore analysed the records of defective boxes during the past 12 months, and has extracted therefrom the following particulars.

TABLE I.—Defective Boxes Found During 12 Months Ending March 31, 1904.

Quarter ending.	Cups damaged by short-circuit.		Moisture in granite basin.		Total.	
	E.M.F. above earth, as shown on Weston voltmeter.

Mar. 31, 1904	10	11	2	2	12	13*
Totals.....	46	54	4	5	50	59

* Average per mile of single track per annum, 10.

It will be seen from the foregoing table that a total of 109 boxes were found more or less alive during the 12 months in question, 59 of which were alive at an E.M.F. of over 50 and under 500 volts. The author has divided the live boxes into two sections—namely, those under and those over 50 volts—as he has found by experiment that it is quite impossible for any person or animal to feel the slightest sensation of shock from a box which gives a reading of 50 volts or under, and it is only in rare cases that anything approaching a shock can be obtained from a box which gives a reading of less than 100 volts. It will be noticed that out of the total of 109 defective boxes, in nine cases the trouble was due to moisture in the granite basin—that is, to the accumulation of water on the surface of the granite basin under the dope, which formed a leakage path to the top plate. This may be said to be due in every case to carelessness in fixing in the first instance, sufficient care not having been taken to see that the interior of the granite basin was thoroughly clean and well brushed over with a coating of hot dope before the remainder of the dope was poured in. The remaining 100 defective boxes were the result of damage done to the interior of the cups by heavy and repeated short-circuits. These short-circuits are caused by pieces of scrap iron which are picked up by the magnet system and come in contact at the same time with the collecting skate and with a cross-rail at junctions and turnouts. The effect of a number of short-circuits on any one cup is that

Digitized by Google

the interior of the top half of cup becomes burnt and charred, and thus loses its insulating properties; consequently the top plate or stud becomes alive at an E.M.F. which may be anything from a few volts up to nearly the full line pressure.

In this connection it is interesting to note that recent experiments made by the author show that the degree of damage to the cup in the event of a short-circuit entirely depends upon the time element of the circuit breaker controlling the main feeder. When the traction switchboard was installed at the power station, the possibility of the adoption of a surface-contact system had not been considered by the Tramways Committee, and the circuit breakers for the tramway feeders were specially designed to give a comparatively slow break, with the object of preventing the rise of pressure which is frequently caused by the sudden rupture of an inductive circuit. Experience has shown, however, that this is the very worst type of apparatus that could have been selected for use with the surface-contact system, as it allows the heavy current due to a short-circuit to flow for a sufficient length of time to give rise to a considerable amount of arcing or flashing between the carbon contacts inside the cup, resulting in the charring of the latter, and sometimes in the fusion of the copper ribbon. The author is now replacing the original circuit breakers with others of a new type which give a more rapid break with magnetic blow out, and as a result of experiment he has found that with the circuit breaker set to operate at 600 amperes the tramway 'bus bars may be short-circuited a large number of times in rapid succession through the contact making mechanism of the cup without the latter receiving any appreciable damage, and he has every reason to believe that this alteration in the type of circuit breaker will very greatly reduce the number of defective boxes in the future. It will be observed that instances of defective boxes due to short circuits are more frequent in the summer than in the winter months, the reason for this being that light pieces of iron or steel are more easily picked up by the magnet when the track is dry and dusty than when it is covered with wet and sticky mud.

The presence of a metallic stud in the street surface electrically charged at a pressure of 500 volts above earth would at first sight appear to constitute a grave source of danger, but the author would point out that in speaking of a stud being alive at 500 volts it does not necessarily imply that the stud is capable of transmitting a dangerous shock to any animal or person stepping thereon; as an actual matter of fact this is by no means the case, as, owing to the comparatively high resistance of the conducting path formed by the charring of the interior of the cup, the quantity of current that can pass is exceedingly small, and in many cases the readings obtained from the same "live" stud by different voltmeters will vary enormously, a difference of one or two hundred volts being by no means uncommon, this variation being simply due to the difference in internal resistance of the respective voltmeters. In only one instance has the shock received from a "live" stud been attended with serious results, and this occurred on Feb. 17, 1904, when a sheep and a dog were electrocuted through treading on a faulty box on the Tettenhall-road route. This accident was the result of a curious combination of conditions, the absence of any one of which would probably have prevented its occurrence. In the first place, the box had been improperly fixed, the vulcabeston cup was cracked, and the space around it was not properly sealed with dope. A car passing over the box picked up a large piece of scrap iron, causing a heavy short-circuit, which completed the fracture of the vulcabeston cup and separated the top half from the bottom. Secondly, owing to a heavy snowfall the track in the vicinity had been salted, and at that particular spot was more or less covered with a fairly strong solution of brine. Owing to the absence of the proper seal of dope, this brine found its way into the interior of the cup, establishing a low-resistance connection between the "live" lower contact and the top plate, and causing the top plate to become "alive" at practically full line pressure. Lastly, the animals to which the accident happened had been travelling for some considerable distance along the salted track and their feet were saturated with brine solution, thus greatly reducing the resistance of their bodies to the passage of an electric current. Immediately after the accident to the sheep and the dog, and before any warning could be given, a horse attached to a butcher's cart stepped on the same box and was brought down by the shock. It got up again immediately, however, and when examined shortly afterwards by a veterinary surgeon was reported as being none the worse for its adventure. As a result of actual experiments the author is inclined to believe that horses, in spite of the fact that they are shod with metal shoes, are much less sensitive to a shock sustained by stepping on a charged metallic substance than to a shock received from a live conductor falling on them from above.

Several instances have occurred of horses stepping on boxes, which when tested with a Weston voltmeter gave readings of 500 volts and over, and although in the majority of cases the animals were brought down, in no case was there any resulting injury from the shock. The author has on more than one occasion watched a pedestrian step on a box which he has known to be "alive" at a pressure of 500 volts, as recorded by a Weston voltmeter, but in all cases the individual was apparently quite unaware of the fact. The comparative harmlessness of the shock received from studs "alive" at the apparently high pressure of 500 volts is, of course, due to the comparatively high resistance of the charred surface of the vulcabeston cup, and to the fact that there is never under any conditions of breakdown or defect any metallic connection between the top plate and the supply main.

In the case of the overhead system it is evident that there is risk of electric shock from any one of three causes—namely, a fallen trolley wire; a fallen telephone, telegraph, span, or guard wire; a pole which has become alive through the failure of the insulators. Wolverhampton is situated in the midst of a network of tramways, all of which are operated on the overhead trolley system, and, judging by the frequent occurrence of accidents due to one of the three causes mentioned above, the author is of the opinion that the risk of electric shock from one of these causes is at least as great as that arising from the occurrence of a "live" stud. The recent accident in a Midland town, whereby three horses were killed and the man in charge thereof injured by a shock received from a tramway pole in the centre of the street, is a grim illustration of the fact that the dangers of the overhead system are by no means confined to falling trolley wires or charged telegraph wires.

On a large percentage of the tramway systems of this country centre-pole or side-pole bracket-arm construction is largely used, and in accordance with the usual practice the poles are erected in concrete. It is well known that under certain conditions which may frequently occur in practice, these poles are virtually insulated from the general mass of the earth, and can, therefore become charged at a high potential relatively to the earth. When it is considered that in a very large number of cases single insulation only is used between the trolley wire and the bracket arm, it is evident that failure of the straight line insulator which supports the trolley wire—either from mechanical stress or other cause—may result in a pole becoming "alive" at an E.M.F. of anything up to 500 volts, and prove a source of very serious danger to human beings and animals in the vicinity. It is evident, moreover, that the failure of an insulator under the conditions named would not be easily detected under ordinary service conditions, and there would be nothing to indicate the fact that anything was wrong until an accident had occurred. That instances of falling trolley wires and "live" tramway poles do occur with startling frequency in many districts where tramways are operated on the overhead system is undoubtedly true, and that these mishaps are not more frequently attended by injury to human beings or animals

appears to the author to be largely due to the beneficent interposition of Providence. It must be remembered, moreover, that a shock received from a falling trolley wire or a live telephone wire is of necessity infinitely more dangerous than any shock which can be received from stepping on a "live" stud, as in the former case the shock is generally transmitted through the most sensitive part of the body, and there is much greater risk of the "live" substance coming in contact with bare flesh. In proof of this contention it is only necessary to refer to the files of the daily Press, from which it will be found that in nearly, if not quite, every instance where a shock has been received under these conditions, it has proved fatal in the case of animals, and has always been attended with serious and sometimes fatal results in the case of human beings. In conclusion, so far as the question of safety is concerned, the author is of opinion that the balance of advantage lies with a well designed and carefully installed surface-contact system.

Reliability of Operation.

Of almost equal importance to the question of the safety of the public is that of reliability of operation, and no system of electric traction will ever have the slightest chance of success unless it can be regarded as thoroughly reliable under all conditions of service. Owing to the entire absence of any statistical information regarding the number of journeys lost through defects in or failures of the overhead electrical equipment on tramways where the overhead system is adopted, it is very difficult to institute anything like a comparison between the overhead system and the surface-contact system so far as reliability of operation is concerned. From the very commencement of the operation of the tramway system in Wolverhampton the author has kept minute records of every delay that occurred on any route and the cause thereof, together with the number of journeys lost by the cars affected by such delay or stoppage. Thus, if an accident occurs causing a delay of 15 minutes on any one route, the mileage lost is reckoned as the total mileage that would have been run by each car affected by the delay during the period that the stoppage occurred. The accompanying Table II. shows the total mileage lost due to faults in the electrical equipment of the Wolverhampton tramways during the 12 months ending March 31, 1904. Out of a total of 173 car miles lost due to defects in the Lorain surface-contact equipment during the period covered by the above table, it will be seen that only 27 are debited against the track equipment. These were due to the following causes: three car miles were lost owing to a delay arising from an improperly soldered joint in a cable terminal, the remaining 24 miles being lost owing to a top plate situated very close to a cross rail being permanently earthed thereto by a piece of iron wedged between the plate and the rail, it being about 20 minutes before the source of the trouble was discovered. One hundred and forty-six car miles lost due to defects in the car equipment may be classified as follows:

Table III.—Details of Miles Lost Due to Faults in Lorain Car Equipment.

	June quarter.	September quarter.	December quarter.	March quarter.	Total.
Earthed magnets ...	22	21	16	20	79
Buckled skates	10	7	20	3	40
Battery faults	8	6	—	3	17
Other causes	3	5	2	—	10
	43	39	38	26	146

It will be seen that during the period in question the total number of car miles lost due to defects in the electrical equipment of both cars and track averaged 3⅓ car miles out of every 10,000 car miles run, and having regard to the fact that during the months of February and March there were frequent and heavy snowfalls, the author is of the opinion that this constitutes a record of regularity and service which it is difficult to surpass.

In considering the car miles lost due to the Lorain-car equipment, it must be remembered that the defects which were the cause of the delays have a parallel in the case of the overhead system in respect of broken and damaged trolley wheels and trolley poles, and in the earthing of the cables inside the trolley standard. The first heavy snowstorm since the system has been in operation occurred on Feb. 17, 1904, when about 6in. level fall of snow occurred in the early hours of the morning. The electrically-driven snow sweeper was at once put into service and the lines were kept clear without difficulty, and no delay of any kind occurred. It is noteworthy that although the snowfall in the surrounding districts, operated on the overhead trolley system, was not quite so severe as it was at Wolverhampton, yet considerable difficulty was experienced, especially in the early morning, in maintaining a regular service. Owing to an abnormal rainfall in the early part of September certain routes were flooded, and at one point the track was submerged for a considerable distance to a depth of nearly 2ft. No trouble, however, was experienced as regards the running of the cars, and no defects developed in the car equipments, in spite of the soaking to which they had been subjected.

In considering the respective liabilities to breakdown of the rival systems, it should be borne in mind that in the case of the surface-contact system as installed at Wolverhampton, any accident or breakdown can only affect one, or, in very rare cases, two boxes, and the momentum of the car is sufficient to enable it to coast over the short length of track thus disabled. Further, any faulty box can be removed and replaced by a new one in an average time of 15 minutes, without any interruption of service. It may in effect be said that the surface-contact system is equivalent to an underground trolley wire divided into 10ft. sections, each of which is independent of the rest, and may be removed and replaced without interference with the efficient operation of the remainder. It is in this respect that the surface-contact system has, in the author's opinion, a distinct advantage over the overhead system, inasmuch as with the latter an accident of any kind to the overhead equipment usually means the putting out of service temporarily from a quarter of a mile to half a mile of route, and a total cessation of traffic along the section affected for a more or less lengthy period. Another respect in which the surface-contact system possesses a marked advantage over the overhead system is that the conductors are free to devote the whole of their time to the collection of fares and to looking after the convenience and comfort of passengers. In nearly all of the tramway systems at present in operation in this country a considerable proportion of the conductor's time is occupied in nursing the trolley pole through frogs and crossings or round awkward curves on the overhead equipment, but in spite of the care which is taken in this respect, interruptions of service are frequently caused through the trolley pole jumping and displacing a portion of the overhead equipment. Similarly also, no reversal of the collecting apparatus is required when changing the direction of running of a car, whether at a terminus or elsewhere on the line, and consequently there is no risk of an accident occurring through forgetfulness or carelessness on the part of the motorman or conductor.

One of the most attractive features of the surface-contact system as installed at Wolverhampton is that it is virtually "fool proof," inasmuch as it is practically beyond the power of the motorman to inflict damage thereon by careless or incompetent handling of his car, and in this respect it possesses an advantage which is not shared by any other system of electric traction. As a result of the 2½ years' experience the author has had of the operation of a surface-contact system, he believes that for reliability of operation it has many and noteworthy advantages over either the overhead trolley system or the conduit system.

Cost of Operation and Maintenance.

This question must always be a determining factor in the choice of a system of electric traction, as under the present *régime* of municipal control, with its attendant low fares and high wages, it is becoming an increasingly difficult matter in many cases to maintain a tramway system as a paying concern, and consequently it is of great importance that the system of traction adopted should be one that will require the minimum annual expenditure to maintain it in a safe and efficient working condition. It must be admitted at the outset that from the point of view of cheapness of operation and maintenance, no system of electrical traction can rival the overhead trolley system. The following statement shows the expenditure on the maintenance of the Lorain surface contact system at Wolverhampton during the 12 months ending March 31, 1904.

Digitized by Google

TABLE IV.—Repairs and Maintenance Costs of Lorain System for 12 Months ending March 31, 1904.

Track Equipment.

	Total cost.	Cost per mile of single track.	Cost per car mile.
Repairs and maintenance of cups and top plates	£125 5 5	£11·3	·058d.
Raising top plates	5 19 2	0·5	·002d.
Miscellaneous repairs	12 2 1	1·1	·005d.
Inspection and testing of track	94 15 6	8·6	·044d.
	£238 2 2	£21·6	·11d.

Car Equipment.

	Total cost.	Cost per car per annum.	Cost per car mile.
Repairs and maintenance of magnet systems	£72 13 2	£3	·033d.
Repairs and maintenance of switches and batteries, including charging	20 3 4	0·8	·009d.
Repairs and maintenance of collecting skates	115 11 8	4·7	·053d.
Inspection and adjustment of magnet systems and collecting skates	102 13 11	4·2	·047d.
	£311 2 1	£12·9	·144d.

The expenditure under the heading of track equipment the author considers to be very reasonable, and is of opinion that it will bear comparison with the cost of maintenance of any similar length of overhead equipment running in a busy manufacturing town. The whole of the work of inspection and testing of the electrical equipment of the track, the removal and replacement of faulty boxes, and the execution of all repairs of every kind required in connection with the maintenance of the electrical equipment of the 15 miles of single track is performed by two men, who are paid wages of 32s. and 28s. per week respectively. The working day of approximately 17 hours is divided into two shifts, so that there is only one man on duty at a time. Every box is tested once a week, and the boxes in the vicinity of points and crossings and other special track work where there is a liability to short-circuits are tested daily. During the period covered by the foregoing statement of costs, the average time required to test about 11 miles of single track was 10 hours, the apparatus used for testing consisting of a portable Weston voltmeter slung round the neck of the operator, the flexible leads from the voltmeter being attached to terminals on a pair of walking sticks, one of which was placed on the box to be tested and the other on the rail. As this method of testing proved to be a slow process, the operator not being able to cover more than about one mile of single track per hour, the author has devised an arrangement by which a light trolley carrying a contact skate can be towed behind any car in service, and by this means every box on about 15 miles of track can be tested in 2½ hours. It is expected that this will result in a considerable reduction in the expenditure on inspection and testing of the track. The expenditure on the inspection and maintenance of the car equipment has been rather heavy, the items relating to the magnet systems and batteries being, in the author's opinion, abnormal, and considerably in excess of what may be expected in the future. It is impossible to obtain reliable figures as to the cost of inspection and maintenance of the trolley wheels, trolley poles, and standards in the case of the overhead system, as records apparently are not kept separately of the expenditure incurred in these respects, but it is probable that the car equipment of the overhead system can be more cheaply maintained than that of a surface-contact system.

One of the most serious disadvantages of the surface-contact system is the increased consumption of electrical energy involved. The additional quantity required varies according to the type of surface-contact system adopted, but with practically every type of system there are three causes which must involve additional current consumption, and these are as follows: firstly, the energy required to operate the circuit closing mechanism of the track equipment; secondly, the additional energy necessary for the propulsion of the cars owing to the extra weight of the special apparatus carried on the car; thirdly, the surface leakage from box to rail over the paving under each car on the track. Of the above-mentioned sources of power waste, the first two only need be seriously considered, as in the case of the third the amount of energy wasted by surface leakage is so small as to be negligible.

(To be continued.)

TWENCEN DOMESTIC TELEPHONES.—The Berliner Telephone Manufacturing Company, 200, Upper Thames-street, London, E.C. (fifth edition), gives illustrated particulars and prices of accessories for domestic telephones, bells, hand-combinations, portable telephones, switchboard accessories, etc.

WIRELESS TELEGRAPHY IN WAR.

We publish, by special permission of the editor of the *Times*, the following extract from a private letter received by mail from their operator at the wireless telegraphy station at Wei-hai-wei:

De Forest Wireless Station, Wei-hai-wei,
North China, April 10, 1904.

I have delayed writing until I could give definite statement about the work. Owing to the movements of the boat we did not have an opportunity to get a good test-out until last night.

Before saying more I will relieve your mind. One-hundred and fifty miles both ways in calm weather and 125 at other times will be good enough, don't you think? That was the result of the test last night, first test, and I am sure it will stand good. In rough weather the boat rolls, shakes, and jars so badly that Brown can't hear me beyond 125 miles.

The troubles and snags I've been up against on other jobs fade to a mere shade compared to this. Placed as we are, in an out-of-the-way corner, where it is well nigh impossible to get anything done, it doesn't take much to put you in a bad hole in this work. A few more jobs like this and I'd begin to sprout grey hairs . . . that's no dream.

Perhaps the importance of our mission and the fact that all eyes were upon us, as it were, spurred us on. The country is full of wireless, and we are showing 'em a thing or two.

I can't begin to tell you all the trouble we had. Anyway it would make poor reading, and I don't know that I care to rehearse it either.

The topmasts fitted on the boat at Shanghai went down the first night out. On our arrival here there were a few old junk masts lying on the ground, no houses for us, nothing even started. It took several weeks to raise a mess of rotten wood about 170ft. high. The country hereabout, by the way, is almost devoid of timber, and it is very hard to get any kind of poles.

Several of our cases were badly damaged on the trip, mostly the Secor stuff, and that gave us a lot of trouble. The engine-houses fared worst, and small parts on engine were broken and bent in bad shape. The bright gentleman who packed the engine oil put the tins in a box and drove nails through them. About half the oil, rather, nearly all in some cans, had leaked out when we unpacked. That damaged engine gave me the time of my life, but I finally mastered it, and now it is doing its part all right.

While the "Haimum" was coaling in Japan another topmast was fitted up, but only one, so that we can only run wires straight up and not across from mast to mast. They didn't seem to want to go to the trouble of two topmasts, so we get along with one.

Owing to the peculiar circumstances in erecting the pole, the shacks were not built until the pole was up, and of course, with Chinese to build the shacks, that in itself was a big job. A Chinaman works half an hour, and then sits down and smokes for a quarter of an hour. If there are 20 on a job, five will be working and the others squat around smoking and looking on. At the time the shacks were built it was the Chinese New Year, which lasts from one to three weeks. It was very difficult to get any of them to work, and those who did went their own gait or not at all.

Although the putting up of the poles and the houses took several weeks, the correspondents seemed to have an idea our part would take no time at all, and as soon as their part was finished were in a great hurry. You said in your memo., "Stations must be working within three weeks."

Including nearly, or the best part of 3½ days' work on engine and generator, we equipped the shore station in six days, and equipped the boat in one day completely. We didn't twiddle our thumbs much that week.

Nine days after we began to work the pole blew down, and another week was required to repair it. During that week I strung up two wires about 80ft. high, and we worked that 60 miles, losing no time on our work.

There is an almost continuous succession of high winds here, and my antennæ have been carried away three or four times.

On the boat we are grounded to the hull, and have a four-wire antenna a little less than 100ft. high.

With the repaired pole on the shore station we have a scant 150ft. of antenna. The site is on the top of a cliff, about 150ft. above the sea, with a rocky hill sloping sharply up to one side, rising higher than the pole. I forgot to mention that we are on an island 1½ by two miles in area, a mass of rocky hills rising several hundred feet above sea-level. The site we have is the best procurable on the island—Liukungtao—and there is no suitable site on the mainland within four or five miles of the office.

I am going to have several photos taken, and will forward them within two weeks.

As I said before, the country is full of wireless, and we have any amount of competition; not in Press work, however. All the British warships, from the third-class cruisers up, are equipped with Marconi, about 24 in all; nearly all the Japs have wireless equipment; the Russian ships are equipped, and several German vessels. One or another of them can be heard any time, day or night. The Japs are particularly numerous, and we are at it all the time.

We laugh at them, for we have struck some good points in tuning, which settle them very nicely. On the boat, when receiving our stuff, two of the four wires are grounded directly, which gives best results. Any resistance between those wires and the ground weakens the signals. If we want to hear the Japs call, disconnecting ground wire entirely from syntoniser of the receiver brings them in strong, while with the ground wire on, as in receiving our stuff, the Japs come very faintly.

On the shore station it is different. Three wires are best in receiving

Digitized by Google

up to 100 miles, with the other two wires free, at which time the Japs came in weakest. By grounding the other two wires the Japs come in very strong and our stuff weakest. Above 100 miles our stuff comes best with two wires grounded directly. That, of course, allows others to come in, but they are not strong enough to prevent my reading through. So far that tuning is best, and certainly gives very satisfactory results.

There are always one or more British warships lying here, and we have them all wondering. The lieutenants of two torpedo boats have told me they do not depend on more than 40 or 45 miles regularly, and another says he can depend on 60 miles. The last one has 160ft. of wire to do his 60 miles, while our boat has a scant 100ft. of wire, and easily covers more than double the distance. Our speed is a source of wonder and admiration to these British officers. I saw some of their tape after we got through with it, and couldn't read a word.

MUNICIPAL ELECTRICAL UNDERTAKINGS.

The Select Committee referred to in our leader in the last issue have formulated the following clauses in lieu of the Bermondsey clause:

1. The undertakers shall, so soon as the annual statement of accounts of the undertakings under this order and under the ——— Electric Lighting Order, 1898, has been filled up in the form prescribed by the Board of Trade under the Electric Lighting Act, 1882, publish in a newspaper circulating in the borough a notification that such statement of accounts has been filled up, and that copies of it can be obtained at the offices of the undertakers at a price not exceeding 1s. a copy, and such publication shall be in addition to, and not in substitution for any publication prescribed by the Board of Trade under the Electric Lighting Act, 1882.

2. The undertakers shall on the expiration of the third complete financial year after they have commenced to supply electrical energy under this order and on the expiration of each third succeeding year reconsider, and if necessary revise, so far as is reasonably practicable, and thereafter maintain the scales of prices charged for electrical energy under this order and under the ——— Electric Lighting Order, 1898, respectively so that no rate will be required for the purpose of defraying the future expenses of the said undertakings during the next three years: Provided, nevertheless, that (*a*) the prices to be charged shall not exceed the *maximum* prices which may be charged under this order and the ——— Electric Lighting Order, 1898, respectively; (*b*) the scales of prices so reconsidered and revised may be from time to time in like manner reconsidered and revised by the undertakers.

3. Nothing in this section contained shall prevent the undertakers from entering into contracts for periods which may extend beyond the periods at which any revision may take place under the provisions of this section on special terms under special circumstances not applicable to ordinary consumers, but each such contract shall provide that the price to be charged for energy supplied under such contract shall either (*a*) be subject to revision at the next triennial revision provided for in this section, or (*b*) vary in the same proportion as the prices charged to ordinary consumers. Provided that the undertakers shall not without their consent be required to accept any price lower than the *minimum* price mentioned in such contract.

TRADE NOTICES AND NOVELTIES.

A Model Cable Factory.

Messrs. Johnson and Phillips have now completed the recent extensions to their cable department, and we understand that the new shops include the very latest equipment for the manufacture of dry-core telephone cables, and they are at present engaged on an order for the General Post Office amounting to some 730 miles. The whole of the new machinery is of their own design and manufacture, as also are all the motors and electric power plant used in the factory, and it is satisfactory to know that this latest system of driving shows a considerable saving over the former method of using separate steam-engines. A construction and cable-laying department has now been organised, and is fully employed on Admiralty contracts for the Portsmouth and Pembroke dockyards, as well as cable-laying at Handsworth, Weymouth, Birkenhead, and Ipswich extensions. We understand that at the end of the present financial year the firm propose opening up a vulcanised bitumen shop and laying down certain wire-drawing plant for drawing their own copper wire.

Electrical Pumping Machinery for Ashington Colliery.

We are informed that Messrs. Ernest Scott and Mountain, Limited, of the Close Works, Newcastle, have recently secured a contract from the Ashington Coal Company, Limited, for an extensive installation of electrical pumping machinery for their Ashington collieries. The current will be taken in two circuits from the main switchboard in the generating-room, one circuit being taken down the Bothal shaft and the second circuit down the Carl shaft, and from the bottom of these shafts the three-phase current will be distributed at a pressure of 500 volts to the various pumps underground. From the Bothal shaft an existing endless-rope haulage gear will be driven by a 30-b h.p. electric motor, and from the same cables current will be taken to the five sets of pumps with a total capacity of 750 gallons per minute against heads varying from 120ft. to 329ft. In the Carl pit there will be two pumps at the shaft bottom delivering 75 gallons of drinking water per minute each against a head of 600ft., and, in addition, there will be four sets of pumps distributed underground having a total capacity of 650 gallons per minute, delivering against heads varying from 150ft. to 290ft. In the relief pit a set of main shaft pumps will also be provided to deliver 300 gallons per minute against a head of 317ft. The whole of these pumps, together with the electric motors, which will be of the three-phase, slip-ring, induction type, will be of Scott and Mountain's manufacture. The whole plant will be made at their works in the Close, Newcastle-on-Tyne. The pumps are of the firm's three-throw horizontal type, fitted with gunmetal rams, the pump barrels, valve boxes, suction and delivery branch pipes being independent and interchangeable. The electric motors will be of the three-phase, slip-ring, induction type, wound for 500 volts, and all motors will be complete with motor-room switchboards fitted with the latest type of switches and instruments. In the shafts the cables will be of the three-core type, armoured with galvanised iron wires; and underground the in-by cables will also be of the three-core type, but unarmoured but suitably supported. This installation, when completed, will be the largest three-phase electric pumping installation in the North of England. The same firm, we understand, have a considerable number of other contracts in hand for collieries, etc., including Consett Iron Company, plant delivering 4,500 gallons per minute, against a head of 300ft.; Croxdale Colliery, 2,000 gallons per minute, 750ft. head; Beckermet Mines, Cumberland, 600 gallons per minute, 1,800ft. head; Barton Coal Company, three sets of pumps delivering collectively 700 gallons per minute, 1,600ft. head; Benwell Colliery, 300 gallons per minute, 600ft. head, together with a large number of less important contracts for pumping, hauling, coal-cutting, etc.

Catalogues.

S.E.C. Electric Motor Fans.—The Sun Electrical Company, Limited, 118 and 120, Charing Cross-road, W.C., descriptive of motor fans for cooling, ventilating, exhausting, and blowing purposes.

Telephones.—Telephone switchboards, wire, insulators, fire-alarms, and all accessories. Ninth edition. General Electric Company, Limited, Queen Victoria-street, E.C.

The Compleat Controller.—Sturtevant Engineering Company, Limited, 147, Queen Victoria-street, E.C. Gives particulars of the Sturtevant electric motor and dynamo controlling apparatus.

"Patrick's" Metal.—Under the above name J. C. Lyell and Co., Limited, 55, Victoria-street, S.W., are placing on the market a new alloy, as a substitute for nickel plated goods, which is silver-white through and through. It is claimed that the new metal resists most acids, and is not affected by sulphur, lime, salt-water, etc., and that it will easily solder and braze, and will take good threads. It is supplied in ingots for casting purposes, and also in the finished goods in the form of electrical fittings, motorcar fittings, etc.

Safety Valves.—J. Hopkinson and Co., Limited, Head Office and Works, Huddersfield (London office and depôt, 165, Queen Victoria-street, E.C.). This list (No. 150) has been issued June, 1904, and fully describes and illustrates the various types of Hopkinson's patent valves, spring relief valves, lever safety valves, and accessories. We also note Hopkinson's "metallic" cement and "graphite" jointing material for high-pressure steam joints.

APPOINTMENTS VACANT.

Switchboard Attendant, Swindon Corporation. Wages £1. 7s. 6d. per week, increasing £6. 10s. per annum for the first two years. Applications by July 5. See advertisement in former issue.

Borough Electrical Engineer, Limerick. Salary, £160 per annum. Applications by July 4.

Electrical and Mechanical Engineer and Draughtsman speaking English, German, and French. Apply to F. L. M., *Electrical Engineer* Office. See advertisement.

Premium Pupil, power and lighting company. See advertisement.

Three Switchboard Attendants at 22s. each per week, one Fireman at 20s., one Dynamo Attendant at 18s., Londonderry.

Rolling-Stock Superintendent, London County Council Tramways Department. Salary, £400 per annum. Applications by 10 a.m. on July 16.

Parcels Superintendent, Bradford Tramways Department. Salary, £150 per annum. Applications by July 9.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Bound Volumes of "The Electrical Engineer," *containing half-year's copies, bound in Dark-Blue Cloth, Gold Lettered, price 8s. 6d. New Volume July to December, 1903, now ready.*

CONTINUITY OF POLICY.

In his Presidential Address Mr. T. P. Wilmshurst has called attention to lack of continuity of policy in legislation. The reason for the state of things that brings about lack of continuity is simple—there is no policy, never has been, and possibly never will be. Legislative policy is a cork borne hither and thither according to the formula and fashion of the moment, or like the thistle-down the sport of every cross gust of political wind. You can get whatever you want from Parliament provided there is no opposition. So far from being a benefit to industry the legislature has from time immemorial always provided a drag upon natural means of expansion, and it is continually chopping and changing its attitude so that capital has to fight more up-hill than would be found necessary if there existed a good or even a bad policy in any direction. Electrical progress has been, and is, hindered on all sides by the flabbiness of legislation. Mr. Wilmshurst points out a variety of directions in which one thing has been done at one time and the opposite permitted at another time. The famous or infamous Bermondsey clause seems in a fair way of extinction; but we are not sure that the clause in substitution will be found flawless. To put this matter a little bluntly, there are two classes concerned in electrical undertakings: (1) those who desire them, (2) those who oppose, these latter being generally competitors of some kind or another. Most of these electrical undertakings are of the nature of businesses. If that is so, they should be organised and conducted as businesses, and every outside interference with a business is bad for that business. All such clauses as that known as the Bermondsey clause and its substitutes are unmistakably interferences and bad. At the present juncture neither municipalities nor companies know exactly where they are. A graver, and even more far-reaching case, is the permission of competing undertakings within the same areas. If the competitors alone were concerned we should not object, but anything that interferes with the general public in the use of roads and streets leads to indirect as well as direct losses, which in the aggregate must be enormous, and which seem never to be taken into consideration. Mr. Wilmshurst calls attention to other vagaries, such as laying obligations upon one undertaking, and leaving the competitor free from any similar obligation. With this cumulative evidence of crass stupidity, it is difficult to realise that the legislative body is composed of men supposed to know something of trading conditions and requirements. The association in whose name Mr. Wilmshurst is speaking is, as he says, a responsible body, controlling a capital of nearly forty million pounds. In order to utilise this vast capital to the best advantage as few restrictions as possible should be placed upon the enterprise, and those so placed should certainly not be dictated by industrial competitors. Another point referred to in this very suggestive address is that of assessment, and here we venture to think that the municipal enterprises are sometimes treated more generously than those of companies. It is hardly correct to say that those controlling the municipal enterprises "have no hand in fixing the amount of our assessments.' Theoretically that may be so, and in the abstract what is sauce for the goose is sauce for the gander, but practically the assessors, if they have a leaning at all, will have that leaning towards their employers. It is true that there is divergence of practice, but the discordance is often of such a character that it would be difficult to standardise. Attempts have been made to do so, but as yet no one has suggested a scheme that meets with general acceptance. The problem is a very difficult one, but, as we say, all engaged in the industry

Digitized by Google

are subject to the same trouble. We must congratulate Mr. Wilmshurst for his boldness in writing so suggestive an address. The points he makes will meet with general acceptance, and should cause those who have power in simplifying industrial operations to think of the effect of constant vacillation upon development.

WIRELESS TELEGRAPHY.

BY R. G. BLAINE, M.E., A.M.I.C.E., ETC.

(Continued from page 922, Vol XXXIII.)

Wireless Telegraphy in France.

France has not been behindhand in this matter. We have already referred to the classic experiments of Prof. Branly in connection with phenomena previously noticed by Prof. Hughes and Prof. Calzecchi Onesti—viz., the fact that an imperfect contact (microphonic or that of filings) becomes comparatively a good conductor under the influence of electrical pressure, due (amongst other things) to ether waves from a distance. Onesti introduced his filings into the secondary of a Ruhmkorff coil, Branly found that the spark of a coil or condenser at a distance rendered his coherer or "radio-conductor" conducting. Since this important discovery was made many experimenters have been at work at various times in France.

In 1898 M. Ducretet made experiments between the Eiffel Tower and the Pantheon in Paris, a distance of 4 km. (2½ miles), and found that the Eiffel Tower worked well as a receiving station, but not as a transmitting station In 1899 M. Ducretet made other experiments between Sacré-Cœur and the Pantheon, and also over the fortress of Bicêtre, between Villejuif and the station in Rue Claude-Bernard (5½ km.). These experiments attracted little attention as the distances were small, and they were undertaken in a city. M. Ducretet used different kinds of apparatus, patenting most of them either in his own name or in conjunction with Prof. A. Popoff, whose important work deserves special notice.

In 1899 M. Tissot (a naval lieutenant) made experiments with the Ducretet apparatus between the lighthouse at Trézien in Corsica and that at Stiff (Ushant), the distance being 32 km. (20 miles); also between Stiff and the lighthouse at Vierge Island, 42 km. (26¼ miles). Further reference to M. Tissot's results will be made presently.

Experiments of Popoff.—In 1895 Prof. A. Popoff, the distinguished physicist of Cronstadt, made many experiments on atmospheric phenomena. He connected a coherer fitted with an automatic tapper to a lightning conductor, and with a relay and Morse printer in the circuit obtained important records of electrical disturbances at a distance. Prof. Popoff has made many experiments since that time, and has lately brought out a new coherer which has been successfully employed in conjunction with a telephone receiver. In this coherer little bands of platinum are placed in proximity to each other in a small tube of glass or other insulating material. In the interior of the tube, and in the spaces between the bands, are grains of steel. The distance apart of the platinum bands is determined by the fineness of the grains. The state of oxidation of the surface of the grains assures great sensitiveness in the apparatus. The novel point in the coherer seems to be that the surfaces of the platinum are lengthwise in the tube instead of across it, as in most coherers. Thus, the surface exposed to the action of the steel dust is greater, and the sensitiveness is correspondingly increased. The general form of the coherer may be gathered from Fig. 51, which also shows the arrangement of receiving circuit adopted.

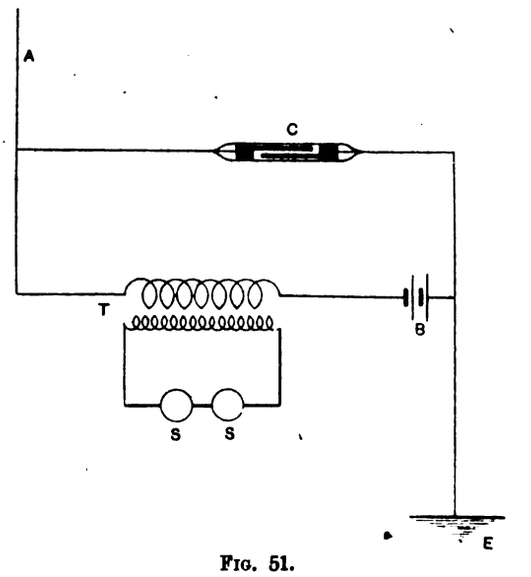

Fig. 51.

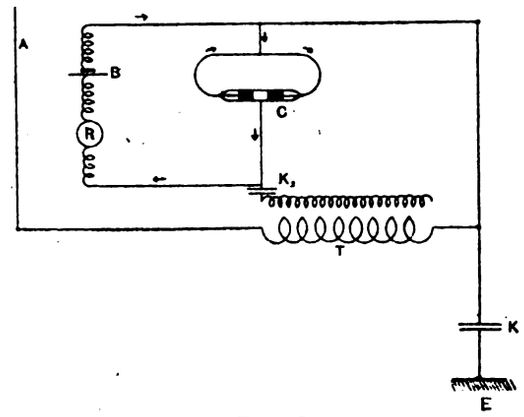

Fig. 52.

A is the aerial or antenna, having in its prolongation the primary coil of the transformer, T. B is a battery and C the coherer. The secondary coil of the transformer has the telephone receiver, S S, in its circuit. The battery is not indispensable, but strengthens the received impulses. Prof. Popoff, using this method, has been able to attain regular transmission of messages over distances of from 36 km. to 50 km. (22½ to 31¼ miles). For instance, communication has been established since February, 1900, between an island in the Gulf of Finland (Hogland) and the continent. One of the stations is placed near a country wood, and several islands intervene between the stations. The masts carrying the antennæ are 48m. (157½ft.) high, and a regular service of communication is carried on.

The Ducretet System.—M. Ducretet, as already stated, has made many experiments and tried various systems at different stations in France. In Fig. 52 one of these is represented in outline as far as regards the receiving circuit and apparatus. The waves received by the aerial, A, traverse the primary coil of a transformer, T, and are directed towards the ground through a condenser, K, the secondary coil of the transformer being in communication with the coherer, C, through an intermediate condenser, K_2. The coherer forms part of a circuit comprising the relay, R,

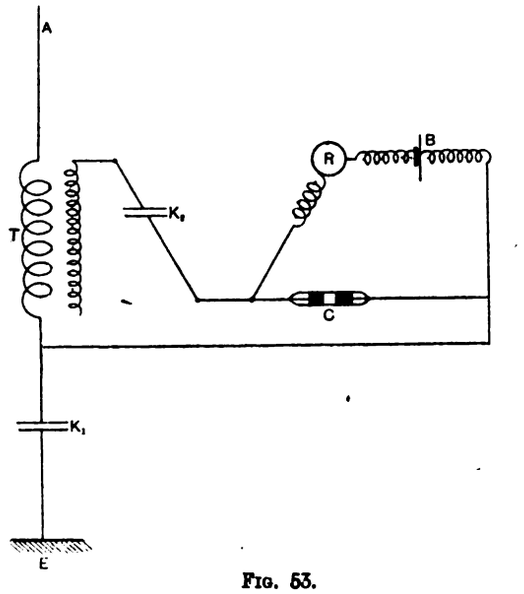

Fig. 53.

Digitized by Google

and cell, B, which circuit communicates with the earth through the condenser, K. Another arrangement is shown in Fig. 53, where the coherer has *three* terminals instead of two, as before. The filings or metallic dust used in this coherer are of steel mixed with silver or rhodium. The arrangement will be understood from the figure. There is the transformer as before, the two condensers, the coherer, and choking coils to prevent the vibrations received through the antenna being wasted in the cell or relay.

Experiments of M. Tissot.—Many of M. Tissot's important experiments deal especially with syntonisation. He has tried to realise syntonic transmission by utilising the arrangements described by Mr. Marconi, especially that including the "jigger." Although he has tried to follow scrupulously the indications furnished by Mr. Marconi in connection with the subject, he has not been able to realise the hoped-for results as far as regards syntony, neither at Trézien nor at the station at St. Martin, where the experiments were carried out. M. Tissot concludes that if Mr. Marconi has realised the transmissions which have solved the problem of syntonisation, it has been by the use of methods other than those described. In the course of his experiments M. Tissot was led to adopt an arrangement which, if not solving the problem of syntonisation, at least augmented the security of selective reception. His arrangement is shown in Fig 54, where A, the antenna, is joined to earth through the primary of an induction coil, T. A wire from the antenna goes to one terminal of a condenser, K, of which the other is connected to earth at E through the medium of the coherer, C. A shunt from the ends of the coherer contains a cell, B, and a relay, R. (For further particulars the reader is referred to M. Turpain's excellent work, "Les applications pratiques des Ondes Electriques.") More recently M. Tissot has been able to increase the distance of signalling very appreciably by employing a peculiar form of coherer. M. Tissot places the coherer tube in a magnetic field, of which the lines of force are parallel to the axis of the tube. The field is produced by a permanent magnet, or, better still, by a coil encircling the coherer tube.

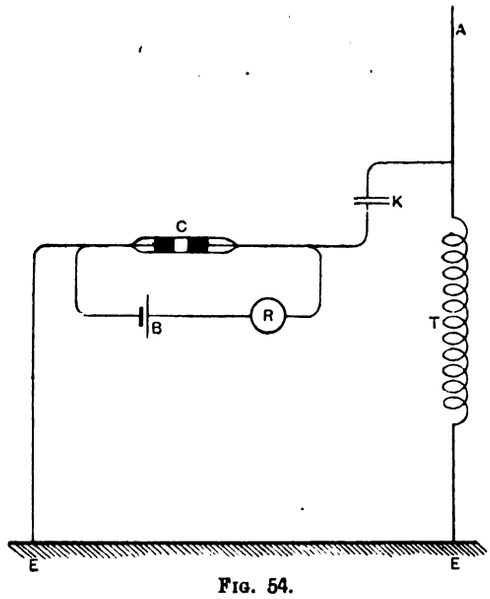

FIG. 54.

In and since 1900 M. Ducretet has to a considerable extent used the telephone as a receiver in the secondary of a transformer or induction coil, and has increased the distance of signalling, as might be expected. He has also in his later coherer employed only a very small quantity of filings between two metal plugs, and has, further, made use of a regenerative coherer of the Blondel type, in which there is a reserve chamber of filings.

M. Rochefort is another successful worker in this field. The Rochefort transmitter has such special features as the Rochefort rotary interrupter and the Rochefort unipolar transformer. In the latter, the whole of the pressure is on one side of the pole—viz., on that side connected with the antenna. He has a receiver the sensitiveness of which can be regulated by a magnet, and he uses the automatic Morse machine of the French Government type, with a resistance in circuit with the coherer to regulate the sensitive of the (Claude) relay. This arrangement has been very successful. Twenty-four stations in and at the disposal of the French navy have been fitted with Rochefort apparatus. M. Rochefort has found out a very important thing—viz., that a coherer can be made to decohere automatically by the passage of a small current through it. When the coherer has been influenced by ether waves, if a current of n milliamperes be sent into it, then under succeeding waves the needle of the ampere-meter in series oscillates between values greater and less than n, returning to about n when the waves have ceased. The value of n depends on the resistance in circuit, the intensity of the waves, and the difference of potential applied to the terminals of the coherer. Stations have also been installed on the French coast fitted with Rochefort-Tissot apparatus. The average distance of signalling between vessels and these stations is about 40 or 50 miles. Vessels fitted with the above apparatus are able to read messages sent out by vessels of the German navy, and also by vessels fitted with Marconi apparatus as well as from the Marconi station at the Lizard.

Marconi's Experiments in France.—In March and April, 1899, Mr. Marconi established communication between a station at Wimereux in France and the South Foreland, a distance of 28⅔ miles, also with a third station at the lightship "Goodwin." These experiments were very successful, clear signals being obtained at all times. Experiments were also tried between the stations named and two vessels, the "Ibis" and "Vienne." The distance of the "Vienne" from the South Foreland was on one occasion 52 km. (32½ miles), and messages were received *by the ship*. Experiments on screening, and also on syntony, were carried out, but an accident prevented the final tests from being carried out. However, between the "Vienne" and Wimereux some experiments showed that messages could not be received by one from the other when they were differently tuned *as long as the distance apart was greater than a certain amount*, but when nearer than this signals could be read just as clearly as if syntonised to suit each other. M. Ferrie, himself an expert in this subject, superintended these experiments for the French Government. M. Ferrie also installed a provisional station at Dunkirk on the occasion of the departure of the French squadron for Russia. He was able to receive telegrams from a number of English Marconi stations, and gives it as his opinion that syntony, as practised at that time, is no protection, or at least only a very limited protection against messages being read.

(To be continued.)

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

701. A few weeks ago I was staying with a friend, when I dropped across something new (to me). He said he had an appointment with a friend, and would I care to accompany him. I consented. It turned out they were experimenting with wireless telephony, one of them worked an ordinary spark coil, giving about an eighth spark. The rest at that end I was not privileged to see, but we got on our cycles and rode to the local club, taking an ordinary receiver of a telephone with us. We connected one wire to the water tap and the other to the gas bracket, and could hear every word that was said at "the other end," about two miles away. Has anyone else seen or heard of anything similar? if so, perhaps the transmitting apparatus would be interesting to others, as well as BRACKLEY-LIAMENA.

Digitized by Google

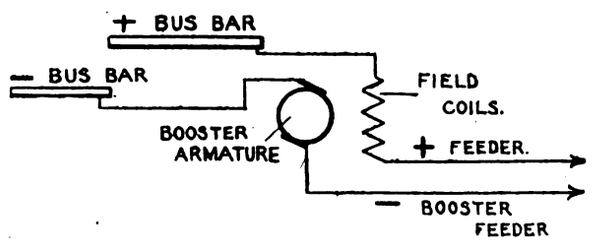
702. On a 500-kw. Parsons turbo generator the two brushes on both poles nearest armature wear down to a knife edge on a 10-hour run; the others doing 40 hours, have changed brushes, and found all contacts to be good. I should be glad if any of your readers can explain this, also give remedy for the same.—W. E. D.

ANSWERS.

Question No. 694.—It is found necessary on a certain tramway route to instal a track booster to reduce the R drop along the rails caused by the current taken by the cars: (1) How would you determine the "boosting point" so that a minimum length of boosting cable may be required? (2) What conditions must be fulfilled by the booster (assuming it to be series-wound generator driven at constant speed) so that it may automatically maintain the rail-drop within certain limits, and also avoid circulating a current when no cars are running? (3) Explain the action of the booster-generator, showing how the potential at the boosting point is reduced and kept at the reduced figure.

Answer to No. 694 (*awarded 7s. 6d.*).—The "boosting point," or position where booster cable should join track, is at a certain point where the drop in voltage on rails from end of track approaches seven volts. The Board of Trade regulations state that there shall not be more than seven volts drop on any uninsulated return. They also compel a tramway authority to keep a continuous record of the drop in the uninsulated return between points furthest from and nearest to the generating station If it is required to use only the shortest possible length of booster cable, almost the whole seven volts drop can be allowed in the rails. In order to determine this the length of line under consideration should be laid out to scale. Cars should be marked thereon, according to service—*i.e.*, on a three-minute service at a speed of eight miles an hour there will be 0·3 of a mile between cars running in same direction. According to size of tramcars, they will take on an average 25 to 50 amperes each at 500 volts. This average can easily be checked by assuming, and marking on plan, that a certain number of cars are stopped or wasting when others are starting or climbing hills. Drop in voltage on rails should be worked out and also marked on plan. Thus it will be seen at a glance where to connect booster cable—*i.e.*, at a point where there is a drop of about seven volts from end of line. It is well to be ·5 to 1 volt, or, perhaps, two volts on low side to allow for emergencies, such as bond loose or race meeting, etc. In the question it is stated that minimum length of booster cable is wanted. It is considered bad practice to lay the minimum length of this cable. When track and bonding is new it will be an easy matter to keep drop in rails within the seven volts, but after a few years' wear and tear it may be necessary to supplement track return by lengths of trolley wire or extend booster cable.

2. The conditions to be fulfilled by booster are very simple. It is to be capable of creating a potential difference across its armature equal to drop in volts on booster cable + drop in armature and fields + a margin for safety or extensions; booster to be able to deal with maximum current likely to be returned through it. A negative booster is generally a serious-wound machine, whose potential difference is proportional to the current returning by the booster feeder. This is one condition required making the machine automatic in action whilst at work. A shunt coil is generally added to give a greater range of action. An improvement in this design, by Mr. Parshall, is shown in sketch. In this machine the field coils are in



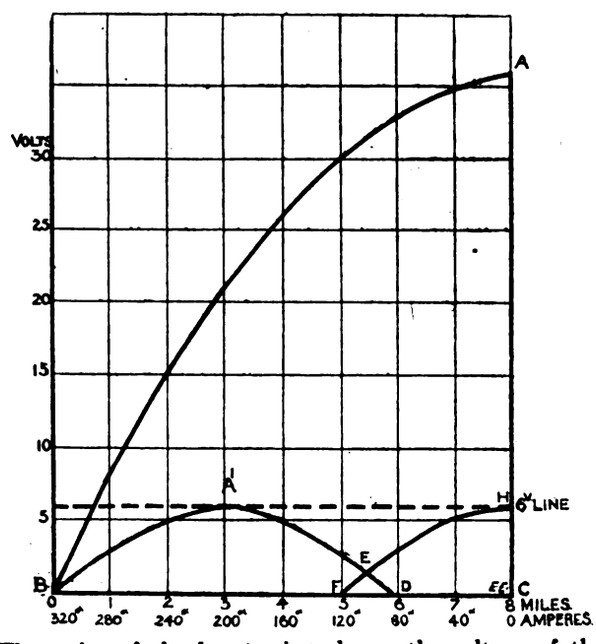
series, with the positive feeder going to the section of line where the booster cable is connected. Thus the booster excitation, and consequently voltage, is automatically regulated in proportion to the load on that particular section. The writer has never heard of any device to prevent a current circulating when no cars are running. A booster, not being an entirely automatic machine, is generally shut down when there is a very light service running, or when that district which it serves is not in use. It is possible to place reverse-current cut-outs on the other earth return feeders, to prevent current leaving negative 'bus bar, going through negative feeder to track, through booster feeder and booster back to negative bar This, to the writer's knowledge, has never been done and is not recommended, it being better to shut down a short-circuit booster when not required to be used.

3 The action of a negative booster-generator has really been explained above in stating that it creates a potential difference across its brushes. By doing this, it reduces the voltage at the station end of the booster cable below that of the negative 'bus bars and track, thus sucking the current along the cable instead of it returning along the rails. A more correct explanation may be that a booster creates a line of lesser resistance through it and its cable than through the track and other earth feeders.—J. H. S.

Answer to No. 694 (*awarded 7s. 6d.*).—To answer the first part of the question satisfactorily it will be necessary to take a concrete example. Let us assume the route is eight miles long and all double track; also 16 cars running, eight on the up track at intervals of a mile, and similarly eight on the down track. We will also assume that two of the cars are at the terminus—one arriving and one departing. Let each car take 20 amperes, and let the resistance per mile of track be $\frac{1}{10}$ ohm. The fall of potential along the track will be:

Terminus									Station.
Miles..	8	7	6	5	4	3	2	1	0
Current (amps.)	40	80	120	160	200	240	280	320	
Potential drop (volts)	36	35	33	30	26	21	15	8	0

On plotting these results we get the accompanying diagram. Now cut a cardboard template to the shape B A C. We will allow six volts as the maximum drop of potential in the rails, which will give a margin of one volt below the Board of Trade limit Set the template on the diagram with the point A on the six-volt line, the side A C vertical, and the curve passing through the origin. This will give the curve B A'. Turn the template over and draw the curve A' D. Again, set the template on the diagram, but with the point A on the six-volt line, and the side A C coincident with the side A C of the original, as shown. This gives the curve F H, cutting A' D in E. The point E, which in the present case is 5½ miles from the station, will then be the best position for connecting the negative booster feeder.

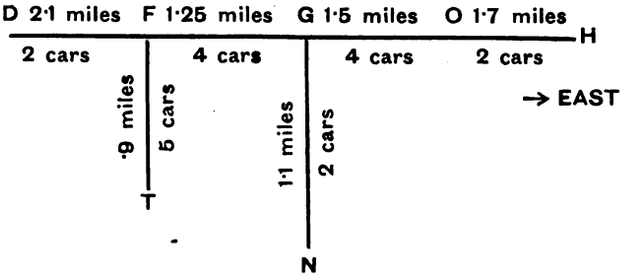


The action of the booster is to lower the voltage of the booster feeder at the station end below that of the track at the station, so that the current will tend to come back through the booster feeder. The line current for the section in which the booster feeder is connected is taken, first through the field coils of the dynamo side of the booster; and, provided the magnets are not saturated, will automatically regulate the voltage according to the load. If

Digitized by Google

connected up in this manner there will be no current circulating when the cars are not running.—C. L S.

Answer to No. 694 (*awarded* 7*s.* 6*d.*).—(1) Assume that the track is single and laid with 90lb. rails or 180lb. rails per yard of track. Assuming the resistance of the rail to be 11 times that of copper of equal section, and that the joints add 5 per cent. to that resistance, a mile of bonded track will have a resistance of ·0289 ohm. To allow for possible increase of service, abnormally busy days, and bunching of cars, the limit calculated on should be five volts, not the whole seven volts allowed by Board of Trade regulations. The integrated product of amperes into miles to give this drop will thus be $\frac{5}{\cdot0289} = 173$ ampere-miles. Starting from the station, sum the product of amperes into miles until this product equals the constant corresponding to the limiting drop—*e g*, 173 in the present case. It is at once clear that all current from cars beyond this point has to return by track feeders. From this point start the integration afresh, and go on until the constant is again reached. At this second point the rails should be at earth potential. Recommence again from the second point and go on till the constant is once more reached. Then all current due to cars between the first and third points should return to the station by a track feeder connected at the *second* point, and so on in succession, the even points marking feeder connections kept at earth potential and the odd points marking the points of maximum potential difference above earth. Obviously, the calculation above described will only give correct results for the distribution of traffic and current assumed. Such assumption can only approximate to average working conditions, and it is only prudent to allow a margin on the upper side for growth and other possibilities. Should there be a large junction near the spot calculated for the track feeder, it would be far better to put that feeder at the junction connecting it to all the branching rails. The following example may make the matter clear, and is taken from Mr. H. Sayer's paper on "Distributing System of Electric Traction": Rail resistance, ·0289 ohms per mile; drop allowed, five volts; amperes × miles constant for five volts; current per car, 15 amperes; cars passing in pairs.



T is the power station. From T eastwards.

	Cars.	Amp.		Miles.		Product.		Sum.
T to F, five cars ·9 miles	First pair.....	30	×	·3	=	9	...	—
	Second pair...	30	×	·6	=	18	...	—
	1 at F	15	×	·9	=	13·5	...	—
	2 on line D F..	30	×	·9	=	27	...	67·5
F to G, four cars 1·25 miles	First pair.....	30	×	1·21	=	36·3	...	103·8
	Second pair...	30	×	1·83	=	54·9	...	158·7
	2 on line N G.	30	×	2·15	=	64·5	...	223·2

As the sum is brought over the constant by the current flowing in at G from branch N G, G should be a point of change of direction. The product of amperes × miles on branch N G is 15 × 1·1 = 16·5. This added to the 158 7 at G = 175·2—a little over the limit. Hence the whole of the 30 amperes from branch, N G, should flow east, and the integral of ampere-miles from G to feeding point should be 173 − 16·5 = 156·5 to keep N at five volts. Then from G eastwards, section G O, four cars, 1·5 miles long, current flowing east 30 amperes from branch, N G.

Cars.	Amp.		Miles.		Product.		Sum.
At G	—		—		16·5	...	—
G to first pair	30	×	·375	=	11·25	...	27·75
First pair to second pair.....	60	×	·75	=	45·00	...	72·75
Second pair to O	90	×	·375	=	33·75	...	106·50

H being terminus, and only two cars between H and O, it is obvious that feeding point should be west of O, so sum westwards from H.

	Cars.	Amp.		Miles.		Product.		Sum.
H to O 1·7 miles.	First pair to O	30	×	·85	=	25·5	...	—
	O to second pair G O...	30	×	·375	=	11·25	...	36·75
	Second to first pair G O	60	×	·75	=	45·00	...	81·00

Feeding point will thus be between the first and second pair of cars east of G. It should be exactly ·825 mile east of G. The product from this point will be 54·75 to the terminus H and to N, corresponding to 1·58 volts drop. Hence the feeding point may be 3·42 volts above earth. The track feeder will have to carry back 120 amperes, and be 2 975 miles long. Section should be ·39 square inch, and the drop in it will be 15 06 × 2·975 = 45 volts; but as its end may be 3 42 volts above earth, the booster will have to give only 41·58 volts, and have an output of 41·58 × 120 = 5,000 watts.

(2) and (3) can be more easily answered together. The positive pole of the booster is connected to the negative bus bar, and the negative pole to the track feeder. The field coils are connected in series therefore with the track return. The booster by reducing the potential at the station end of the track feeder below that of the rails at the station, and thus drawing as it were more current by that return feeder than would otherwise return by it. The difference of potential between the two ends does not remain the same, consequently the voltage of the booster automatically varies. Its effect is such that the current returning by the track feeder is $\frac{E + A R}{r + R}$, whereas if no booster is used it would be $\frac{A R}{r \times R}$; A = total current in the return circuit of the section; E = voltage of booster; *r* = resistance of booster cable and armature; R = resistance of rails. In installing a booster the voltage it should generate can be found from the formula: $E = C (R + r) - A R$, C being the current in the return feeder.—C. A. B.

Question No. 695.—Please give detailed description of the various steps taken to prevent explosions in underground conduits for electric wires. Have any improvements been made in insulators, has glass been substituted anywhere for earthenware with advantage, and is it possible to do without ventilation? One central station using bare copper strip conductors forces hot air into the conduit to keep it dry. Has this been found successful and generally adopted? Are bare conductors now employed underground, or are they now superseded in best practice by insulated conductors? Is bitumen laid in wooden or earthenware troughs found satisfactory insulation, or does the conductor sag too much?

Best Answer to No. 695 (*awarded* 10*s.*).—The usual method adopted for preventing explosions in underground conduits is to seal up all possible passages through which coal or sewer gas can enter the conduit, and deal with the gas which permeates through the material of which the conduit is composed, by either fans or natural ventilation. Fig. 1 is the general form of ventilating box. The gases usually met with in the subsoil are about half the specific gravity of air, and so tend to rise to the highest part of the conduit and leave by the nearest ventilator, being replaced by air at the lower parts, and so the conduit is kept free from explosive mixtures. The insulators as used on the early systems of bare copper conductors, such as the Kennedy and Crompton, have changed very little up to the present time, and they are usually of the petticoat, or modification of that type of insulator, with additional ridges to prevent a film of moisture forming and so arrest any surface leakage. Glass has been largely used for insulators of a squat design, but it is very expensive as compared with earthenware, and the small projections, such as the extensions at sides to prevent the conductor leaving the insulator, will give trouble, as these extensions will probably be broken off if any great strain is put on them, and so porcelain or earthenware is generally used.

With regard to ventilation, it is better to provide for it if possible, as it will, in addition to clearing away any explosive mixture, also prevent fungous growth with its attendant leakages. The system of forcing heated air into the conduit would certainly have a good effect in drying the insulators, but I do not think it is in general use. The bare copper strip systems of underground mains are now very seldom put down, partly due to the excessive cost of construction, and also the uncertainty of finding sufficient space in the footpaths for them. The system is certainly an ideal one if we could prevent flooding, keep the conduit dry and free from gas, as it makes

Digitized by Google

use of the cheap and permanent insulator, "dry air"; but as the distances between conductors must be such that earthing or actual contact cannot occur, even when heavy currents are flowing and expansion and mutual attraction are taking place, the conduit becomes too large, and as the working pressures are on the increase, we find it superseded by insulated conductors. Vulcanised-bitumen insulated cables laid in wooden troughing, filled solid with bitumen, have been very largely used and have proved very satisfactory, but this class or insulation has the same fault

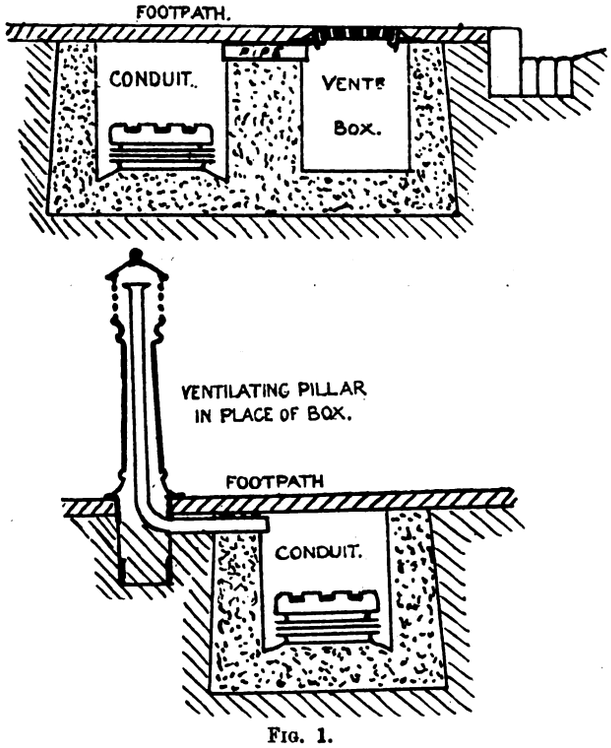


FIG. 1.

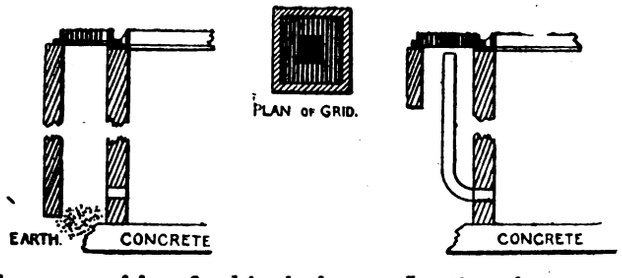
as rubber, in that it becomes plastic at high temperatures and gives off inflammable gases, and a short circuit is generally attended by a lot of damage to other cables if in close proximity. Manilla paper treated with resin oil is an excellent insulation for cables, and most cablemakers are now supplying this for extra high-tension work with great success; but as it is very hygroscopic, it must be placed in a watertight envelope made usually of lead, and greater care must be taken than with vulcanised bitumen, as the ends must be immediately sealed when cut, and all chances of moisture reaching the insulation prevented whilst jointing, and any blowhole in the lead detected before the cable is put to work. With paper-insulated cables we are not troubled by decentralisation as with insulations which become plastic at high temperatures, and thus the copper can be worked at higher density per square inch, where drop in pressure is not important.—A. T.

Answer to No. 695 (*awarded* 5*s.*).—The various steps taken to prevent explosions in underground conduits for electric mains are devoted to two ends—namely, exclusion of gas and ventilation. In New York and also in parts of the Manchester scheme air is driven through the conduits



by means of fans fixed in the boxes. In other places ventilating pipes are taken from the junction boxes to the top of some adjacent house, or even to the base of a convenient arc or tramway pole, in which case the pole would act as a chimney in creating a draught. In yet other places ventilating grids are fixed in the box covers, or a ventilating grid is fixed near the rim of the box and connected by a pipe or brickwork passage to the lower part of the box, as per sketches. To exclude gas, the boxes, where possible, should be made of cast iron. If brick is used, cement should be used for setting, and the walls served on the inside with cement. The floor should be of concrete, and fitted with a trap to carry off any water that may find its way into the box. Glass insulators are now used in many cases. They are lighter and cheaper than glazed earthenware ones, and, although not so strong mechanically, do not depend on the integrity of a thin glaze for their non-hygroscopic qualities.

Until we find a thoroughly gas-proof system it is impossible to do without ventilation. Bare conductors are still employed in many cases, due to the ease with which connections for services, etc., can be made, and the facility for increasing the area of conductors when required. The system most in use at present is Crompton's. It consists of strained copper strip laid on insulators. Either brick or iron culverts may be used. The iron ones are more expensive, but on the other hand there is not that injurious deposit of salt on the negative conductor insulators, which occurs when brick or concrete conduits are used. Lead-covered cables laid in bitumen, in wood or earthenware troughing, with properly spaced distance pieces, say, 18in. apart, have been found to be quite satisfactory, and are in use in many towns.—C. L. S.

Answer to No. 695 (*awarded* 5*s.*).—The chief steps taken to prevent explosions in underground conduits have been to endeavour to render them both water and gas proof. These conditions are practically impossible to maintain. In any extensive system the conduits are laid with a fall which will carry any water, whether from condensation or surface water, to the nearest manhole, and thence, if the quantity is considerable, it is usual to connect, through a non-return trap, to the sewers. The surface frames and covers of the manholes are designed to prevent access of water, and yet ventilating to allow a free passage into the atmosphere of any gas which may have accumulated. Sometimes a pipe is taken from the manholes up the adjacent walls instead. In New York, owing to the soil being gas-ridden, it has been found necessary to continually blow a current of air through the conduits and manholes; this, however, is very expensive. Some engineers prefer the manhole covers to be water and gas tight, and trust to frequent inspection to remove any gas accumulations.

The earliest system of placing bare underground mains in culverts was that introduced by Messrs. Crompton and Co., consisting of a concrete trough in which the conductors are carried on glass insulators, these being mounted on a wooden cross-bar, and the trough covered in with stone flags. In the more recent system due to Prof. Kennedy the insulators are of stoneware, but porcelain has also been used. Generally speaking, all these are satisfactory materials, but as it depends on the shape and non-absorptive properties of the insulator rather than on the material, it would be incorrect to say that glass is better than porcelain. The point to be considered is that the insulators are so designed to make the surface leakage a minimum. At Manchester glass insulators have superseded the original porcelain system owing to excessive leakage. At Glasgow, owing to contacts between the copper strips and the iron culvert in which they were placed, subsequent extensions have been made with insulated cable, both fibrous and rubber.

Bare conductors are still employed underground where there is sufficient space under the pavements for very large mains, and if tapped for frequent services. Here they are undoubtedly best and cheapest, always provided that they are so installed as to prevent sagging of the conductors and leakage. The best practice for smaller-size cables is to have them paper insulated and lead covered, either laid solid in stoneware or wood troughing, or steel armoured and laid direct in the ground where the soil is suitable, these being much cheaper to instal, and take up less space than conduits.

With regard to the question raised as to whether bitumen laid in troughs is found satisfactory insulation, it is not very definite whether this refers to bitumen-insulated cables or simply the suitability of bitumen as a filling-in compound. If the former, V.B. is satisfactory, providing the section of the copper strand is large enough to carry the current

Digitized by Google

without undue heating, otherwise the core decentralises and sinks through the insulation. If the latter, bitumen is thoroughly suitable, but should not be considered as an insulator, but merely as a mechanical protection to the cable. A new system has recently been introduced of laying bare conductors mounted on porcelain insulators in a wooden trough and filling the trough in with compound. This has not been used to any extent, but there is no reason why it should not be satisfactory, always providing that the strand does not work at too high a rate of conductivity, otherwise the conductors will sag, and may even touch each other, with more or less disastrous results. It would also be better to use stoneware troughs instead of wood.—L.H.E.

Answer to No. 695 (*awarded* 5*s.*).—I will reply to the queries in the order set forth in the question. Gas may, of course, filter through the walls (or joints) of the conduit whether of concrete, earthenware, or iron, and also through the brickwork of surface-boxes; and this has often led to explosions of gas, and sometimes serious consequences. This is especially likely to occur where bare mains are laid in concrete culverts, for here the gas can accumulate in large quantity. Opinions differ as to the best means of ventilating the conduit in order to prevent explosions, and it is not at all an easy matter to lay down any hard and fast rule on the subject. Many systems run ventilating pipes from the surface-boxes up the side of the nearest house wall, and this is a good method if provision is made for inlet pipes to take in pure air, for supplying the place of the gassy air removed. This would be a system of natural draught. Some systems have small air-shafts, with 3in. by 6in. iron gratings over, this shaft being built by the side of, and entering into, each surface box. Others use surface box covers with slots or holes for ventilation, but my own experience is that these slots and holes very soon get choked up with dirt, and I think the ventilating pipe up the wall is the best arrangement, though more costly. Ventilating by forced draught should be the best safeguard against explosions, but it is a difficult thing to carry out, and I have not known any place where they do this except Manchester.

In the case of ordinary conduit work I believe that the best thing to prevent explosions is to send a man round very early in the morning to open all the surface boxes by removing the covers for a few minutes, this being done every day. Both glass and glazed stoneware bearers are used for bare copper strip Glass is stronger, but dearer, and I cannot imagine anything better than well glazed and vitrified stoneware for this work. Bare conductors are very rarely employed now for mains, insulated cables being generally used, for the following reasons. The first cost of a culvert to contain bare copper strip is considerably more than for insulated cable. The bare mains in a culvert occupy a much larger space under the pavement than an insulated cable, and in large towns, where the gas and water pipes are already there, no room is left by the gas and water engineers for culverts. The mains' man is lucky to get room for one insulated cable, and then he has to dodge gas and water services at all heights and all angles. Then, again, the culvert requires a straight run between points, whereas an insulated cable can be taken round obstacles to a greater extent.

When overloaded, bare copper mains are liable to warp and twist, putting heavy strains on the bearers and sometimes short-circuiting themselves. This is particularly the case when the copper is of heavy section, made up of a number of strips. The leakage is necessarily high, because the insulation resistance is low and very variable with the weather. The culvert is always liable to flooding by heavy rains or the bursting of a water-main, and this means a serious breakdown. The insulated cable is free from these perils. I have never heard of bare copper laid in bitumen in wooden troughs, and cannot think it would be a success. The trough would have to be very deep to prevent the strip sagging to the bottom—porcelain bearers would be required and great care taken in filling in with bitumen. Even then, when the strip got hot under load, the bitumen would melt, giving off vapour which would provide a passage for moisture from outside. If "Water" *does* try this, I should like to hear the result after, say, 12 months' working. It would be particularly interesting if the main were put down as a distributor with services tapped off, though I shouldn't care to do it myself.—DUPLICATOR.

SWITCHBOARD SONG.

For Use on Holiday Shift.

BY "SIMPLEX."

Wheels!—Wheels!—Turnin' in me 'ead!
Sixteen hours on duty. Wish that I was dead!
Regulatin' voltage till me achin' noddle reels.
Wheels! Wheels! Wheels!

Grunt! Grunt! Piston runnin' dry!
Driver, *can't* you watch it? Want me standin' by?
Like to 'ear it 'owlin' like a dyin' elephunt?
Grunt! Grunt! Grunt!

Crash! Bang! *Knew* how it would be!
Nothin' *ever* happens unless there's only me!
Telephonic message! Lights are out? Oh, *hang*!
Bang! Crash! Bang!

D——n! D——n! Will it never cease?
Haven't got a minute to take me tea in peace!
Bluebottle is dyin' in me *only* pot of jam.
——! ——!! ——!!!

PERSONAL.

The first annual outing of the Brighton Corporation tramways' depôt repair staff took place on Saturday. Under the direction of Mr. M. H. Volk, jun., workshop engineer, the party of 25 drove through Falmer, Lewes, Offham, Plumpton, Westmeston, Ditchling, over the Common to Burgess Hill, and on to Friar's Oak, the residence of Mr. and Mrs. Volk, sen., where a meat tea was provided.

The Southend Town Council have increased the salary of Mr. Heenan by £50 per annum.

Plymouth Corporation tramways inspectors, motormen, and conductors, to the number of 47, had their annual outing on Saturday. The party journeyed to Wadebridge by train, and after having breakfast drove to Newquay in wagonettes. After a short stay at Newquay for lunch, the return journey to Wadebridge for dinner was made. After dinner songs, etc., were indulged in, and Chief Inspector W. Turpin moved a vote of thanks to Messrs. M. H. Maddick and Wilce, secretary and treasurer respectively, for making the arrangements for the trip.

The Epsom Council have increased the salary of the electrical engineer by £25 to £250 per annum from Oct. 1 next, and the salary of the chief assistant by £16 to £120.

On Saturday last, June 25, the second annual outing of the staff of the Stepney Borough Council electricity department took place to Margate. The party travelled in reserved compartments from Cannon-street, arriving at Margate shortly before 10 a.m. At the dinner at Munn's Hotel, in the unavoidable absence of Mr. W. C. P. Tapper (the engineer), the chair was taken by Mr. W. Young, supported by Mr. Mr. A. J. Somerville, in the vice-chair. The latter proposed a vote of thanks to the hon. secretary (Mr. T. J. Archer) and the hon. treasurer (Mr. G. B. Davies) to whose untiring efforts, he said, the great success of that day's outing was largely due. We are informed that the committee are again indebted to Mr. Alderman R. A. Kearsey (chairman of the Electricity Committee), Mr. Alderman C. E. Osman, Mr. W. C. P. Tapper, and also to Mr. Arthur Wright (the consulting engineer) for financial support in connection with the outing.

Mr. John Brindle, who has been manager of the Bury, Rochdale, and Heywood Tramway Company's undertaking for the past six years, has been appointed general manager of the Paisley district electric tramways.

Mr. R. C. Bullough, of Manchester, has been appointed manager of Colchester borough tramways at a commencing salary of £300 per annum.

The Aberdeen Electricity Committee have decided to increase the salary of the chief clerk at the Ferryhill electricity works from £117 to £135 this year and to £150 the following year.

At Worcester, on Thursday last, the Electricity Committee granted a day's holiday to all that could be spared from the staffs of the two generating stations to play a cricket match, played at Powick. After a very enjoyable game the New Station won by 40 runs. Birrell and Gardiner captured all the wickets for the winners, the former in the first innings having an average of six wickets for nine runs. For the losers Knott and Wood bowled exceedingly well. At 1.30 an adjournment was made to luncheon, provided by Mr. C. J. Sutherland, the chief engineer. At the termination of the match Mrs. Sutherland presented the winning team with a handsome silver cup, which he has given to be played for each year.

Mr. F. E. Wilkinson, of Redhill, Surrey, at present engineer-in-charge of the Reigate Corporation electricity works, has been appointed to the post of engineer-in-charge of the York electricity works at a salary of £100 a year.

LEGAL INTELLIGENCE.

FEES TO EXPERTS.

An action was brought by the Lincoln Tramways Company, Limited, in the Lincoln County Court to recover damages from Mr. Alfred Dickinson, civil engineer, of Birmingham, for breach of contract. Mr. Hollis Walker (instructed by Messrs. Hebb and Sills, Lincoln) appeared for the plaintiffs; and Mr. Lindley (instructed by Messrs. Dingnans and Elliott, Walsall) for the defendant.

The proceedings occurred in connection with the sale of the plaintiffs' undertaking to the Corporation. The contention of the company was that the defendant's contract bound him to give evidence before an arbitrator if required, as well as to value the undertaking, for the inclusive fee of 50 guineas. It was stated that after being paid 50 guineas for his report on the concern the defendant wrote asking to be liberated from giving evidence before the arbitrator on the ground of illness. Thereupon, the plaintiffs called his attention to his previous promise, and defendant replied that in the event of his appearing before the arbitrator he should require a certain fee. Eventually the company engaged another expert, a Mr. Fell, to whom they paid a fee of 50 guineas. The matter was finally settled between the company and the Corporation without going to arbitration, the company getting £10,400 for the undertaking, which was £300 in excess of the valuation of Mr. Dickinson. The company now alleged breach of contract against Mr. Dickinson, and claimed 50 guineas damages, which was the amount of the fee they had to pay Mr. Fell.

His Honour, after hearing arguments, said the action arose through want of force in the expressions used by the plaintiffs to the defendant in a certain letter, but when he read that letter with the other correspondence he was distinctly of opinion that the letter was an order to the defendants to inspect the tramways, and undertake to advise the company as to the value, with the proviso that if the sale did not take place the defendant would be required to give evidence before the arbitrator; and he considered that the defendant so understood. Judgment would therefore be for the plaintiffs, with costs.

CORPORATION OF NORWICH v. NORWICH ELECTRIC TRAMWAYS COMPANY.

This case came before Mr. Justice Phillimore on circuit, without a jury. Mr. Macmorran, K.C., and Mr. E. E. Wild represented the plaintiffs, and Mr. Low, K.C., and Mr. F. H. T. Heale appeared on behalf of the defendants.

The dispute hinged upon a clause of the Norwich Electric Tramways Act, 1897. Under the General Tramways Act the Norwich Tramways Company had to keep in repair that part of the roadway which was between the tramrails and 18in. outside as well. The local Act adopted the General Tramways Act, but in the local Act a further burden was placed upon the Norwich Tramways Company, and it was in reference to this that the dispute arose. The local Act provided that if the company failed to maintain and keep in good condition to the satisfaction of the Corporation "the junction of the paving laid and maintained by the Corporation," the Corporation might themselves at any time after seven days' notice to the company, do the work necessary for the repair and maintenance of the road, and the expense reasonably incurred by the Corporation in so doing should be repaid to them by the company, with the addition of 5 per cent. on such expense. The maintenance of the paving involved an expenditure of £700 a year.

Mr. Macmorran explained that where granite blocks were laid in a macadamised road there was a tendency for the macadam to wear quickly. While the granite setts lasted for many years, the macadam used up quickly. He contended that by a section of the local Act it was incumbent upon the company to keep a uniform surface at the junction of the setts with the macadam. The company had failed to do the work, and the Corporation had undertaken it.

The **City Engineer** (Mr. A. E. Collins), **Mr. J. W. Cockrill**, borough surveyor of Great Yarmouth, and **Mr. E. J. Silcock**, of Leeds, gave evidence on behalf of the Corporation.

Mr. Alan Neville Bannister, A.I.E.E., manager of the defendant company, said the roads of the plaintiffs where these steps occurred were generally bad.

Mr. Isaac Emerson Winslow, consulting engineer to the New General Traction Company, and **Mr. Stephen Sellon** also gave evidence on behalf of the defendants.

Counsel on both sides having addressed the Court, his **Lordship** said he would take time to consider the matter.

COMPANIES' MEETINGS AND REPORTS

ISLE OF WIGHT ELECTRIC LIGHT AND POWER.

The annual meeting of the shareholders of the Isle of Wight Electric Light and Power Company was held at the works last Friday, Mr. F. E. Gripper presiding.

In moving the adoption of the report and balance-sheet, the **Chairman** remarked that very satisfactory progress had been made during the year. The Company had practically completed the whole of their undertakings in the island, having supplied East and West Cowes and established works at Ryde. The additions in the number of lamp connections were very satisfactory. At Ventnor they had increased from 12,900 to 15,300, at Sandown and Shanklin the number had increased from 8,100 to 10,100, and at Newport the number had jumped from 6,800 to 16,000. At Ryde and St. Helen's up to the end of the year they had installed 5,000 lamps. This made an aggregate of 46,900, as against 27,900 at the end of the previous year. Taking the first four months of this year, they had had applications for, or had connected up, between 7,000 and 8,000 lamps. Turning to the financial statement, the Chairman said he regarded this as satisfactory, considering that the Company was young. Including a small balance carried forward from the previous year, the profits amounted to £5,640, of which sum £5,400 had been made on the year's working, thus showing that when the directors prophesied a profit of £5,000 when appealing to the public to subscribe to the share capital they were on the right side. The profits for the first four months of the year amounted to £2,641, as against £1,390 for the corresponding period last year. The revenue had been applied to paying interest on their debentures and preference shares; they had written off £500 for renewing accumulators at Ventnor, and were carrying forward a sum of £344. As to the capital expenditure, the Chairman explained that the directors believed in the policy of supplying current to various parts from which applications had been received, and they had invariably found that the number of consumers soon increased very satisfactorily. Their total capital expenditure was £224,000, and they had spent £100,000, £46 000 being in Ryde and St. Helens, and £28 000 in Cowes. In conclusion, the Chairman expressed himself in confident terms as to the ample security held by the shareholders.

Colonel Hamilton seconded the motion, and said that the investment in preference shares and debentures was as satisfactory as one could wish for.

The motion was carried unanimously.

Mr. Gripper was cordially re-elected a director, and Mr. A. H. Crowe was reappointed auditor, his fees not to exceed 25 guineas.

The **Chairman** mentioned that heretofore the directors had not asked for any fees for their services, and he thought the time had come when a nominal sum should be paid. It was decided to pay the five directors £150 per annum, to be so divided as they deemed fit.

Thanks were voted the chairman and directors, and the meeting closed.

BRITISH ELECTRIC TRACTION.

The report for the year ended March 31 last states that the total amount for appropriation, including £24,912 brought forward from last year, is £274,730. The premiums, amounting to £30,042, received in respect of debenture stock issued during the year, have not been brought into this account, but have been carried direct to reserve. After providing for interest on debenture stock, dividends on preference shares, and interim dividend at the rate of 6 per cent. per annum on the ordinary shares for the half-year ended Sept. 30, there is a balance of £78 138. The directors propose a dividend at the rate of 6 per cent per annum on the ordinary shares for the half-year ended March 31, carrying forward £38,148. The sale of the Poole undertaking to the Bournemouth Corporation will be brought into the next year's account. During the past year £232,407 5 per cent. perpetual debenture stock has been issued. An issue has also been made of £250,000 4½ per cent. second debenture stock. The net premiums received in respect of the issues amount to £30,042, and the whole of this amount has been added to reserve. The subscribed share and debenture capital at March 31 was £1,333,010 in ordinary shares of £10 each, £1,564,370 in 6 per cent. cumulative preference shares of £10 each £1,256,225 in 5 per cent. perpetual debenture stock, £250,000 in 4½ per cent. second debenture stock. Since the closing of the books arrangements have been made with a syndicate for the sale of £50,000 5 per cent. perpetual debenture stock and for an advance to the company of £550,000 by instalments with a view to the development and completion of undertakings in hand, and an option has been given by the company to the syndicate to call for allotments, at any time before Dec. 31, 1905, of debenture stocks and shares of the Company, the proceeds of any such allotments to be applied in the first instance to repayment of the above advances, with interest at the rate of 4½ per cent. per annum. The present policy of the directors is to limit, as far as possible, the further capital commitments of the Company. The total mileage of lines in operation by the Company and all its associated companies, by electric traction, steam, and horses, at Dec. 31, 1903, was 327·44, as against 288·77 in the previous year; and the mileage of omnibus routes was 68·87, as against 71·62. The total number of passengers carried on the lines open for traffic in 1903 was 219 714,189, showing an increase of 29 per cent. upon the preceding year; and the total traffic receipts amounted to £1,162,005 showing an increase of 26 per cent. upon the preceding year. The total amount received for electricity sold by the Associated Electric Power and Lighting Companies in 1903 was £40,345, showing an increase of 50 per cent. upon the preceding year. The Company's investments in the tramway companies in Birmingham and adjacent districts have been merged in the Birmingham and Midland Tramways, Limited, whose capital has been increased to £1,050,000, and a joint committee of the Boards of the associated companies has been constituted to operate about 95 miles of tramways and light railways in the district. The directors believe that these arrangements will lead to increased economies in working, and enable greater travelling facilities to be afforded. These arrangements should also enable the further capital required by these companies to be raised independently of the British Electric Traction Company, and an issue of £200,000 debenture stock has recently been made by the Birmingham and Midland Company. Allusion is made to the Bill promoted in the last session of Parliament, which proved unsuccessful, for obtaining running powers over the tramways of the Birmingham Corporation after the expiration of the leases in 1906 and 1911. Temporary agreements have since been made with the Corporation in regard to some of the routes. Further progress has been made by the Metropolitan Electric Tramways, Limited, with the important scheme of tramways in North London and light railways in Middlesex and Hertfordshire, and the first section of about six miles

Digitized by Google

will, it is expected, be open for traffic on the overhead system of electric traction in the course of a few weeks. The Metropolitan Electric Tramways Company has also purchased from the British Electric Traction Company all the shares in the North Metropolitan Electric Power Supply Company, which owns Acts of Parliament giving the right in perpetuity to supply electricity in bulk over an area of about 325 square miles north of London, and an extensive business is in course of being established. A large power-house has been erected at Enfield, and another power-house at Willesden has been acquired from the Urban District Council, who were advised that it would be more economical to purchase the electricity from the supply company in bulk than to generate it themselves for the purpose of retail distribution under their electric lighting order. The undertaking of the British Electric Traction Company to provide capital for the Metropolitan Electric Tramways Company to the extent of £500,000 has been fully discharged. The directors have given much attention to the question of motor haulage and motor omnibuses, and have entered upon several experimental enterprises, but so far without obtaining satisfactory results, and all the expenses incurred have been written off. Experience, however, has been gained in connection with the new industry, which is likely to be of value to the Company in future. No return has yet been received upon the ordinary shares held by the Company in the Brush Electrical Engineering Company, in which the Company is now largely interested, but that company has made satisfactory progress during the past year. The Company and the Brush Company jointly obtained a concession for electric tramways at Shanghai, on condition that substantial commencement of the works should be made within one year from April 21, 1903. In view of the political outlook in the East last year, an application was made for extension of time, which the municipality declined to grant. There was, therefore, no alternative but to accept the suggestion of the municipality and to withdraw from the business, as the directors felt that the expenditure of a large capital on tramways in Shanghai at the present time could not be justified. The Brush Company has secured a valuable interest in a concession for electric lighting and tramways in Bombay, and the works for electricity supply are being proceeded with, but the electric tramway enterprise is delayed by various negotiations, and by arbitration proceedings between the Corporation of Bombay and the existing owners of the tramways.

NEW COMPANIES REGISTERED.

Phonograph Record Manufacturing Company, Limited.—Capital, £1,000. Object: to carry on the business of manufacturers of and dealers in gramophones, phonographs, talking machines, records, electrophones, telephonic apparatus, etc. Registered office: 99 to 119, Rosebery-avenue, E.C.

Liens Registered.

Kyma Car Company, Limited, Peckham Rye, S.E.—Debenture registered June 17, for £140; charged on the undertaking and all the property, including the uncalled capital for the time being.

Bromley (Kent) Electric Light and Power Company, Limited. An acknowledgment of indebtedness under seal, dated June 6, 1904, creating £20,000 further debenture stock (making, with £50,000 already created, a total of £70,000, and being supplemental to a trust deed, dated July 7, 1902), has been registered. Property charged: the company's undertaking and property, present and future, including uncalled capital. Trustees—F. T. Medcalf, 9, Great St. Helen's, E.C.; and W. R. Davies, 10, Moorgate-street, E.C.

Midland Electric Corporation for Power Distribution, Limited, Liverpool.—Discharge registered June 22 of mortgage dated Nov. 13, 1902, for £100,000.

British Electric Calibrated Fuse Company, Limited.—Issue on June 6 of £300 debentures, part of a series created Dec. 4, 1903, to secure £3,000, charged on the company's undertaking and property, present and future, including uncalled capital. Holder—J. Lang, 137, Fenchurch-street, E.C. No trustees. Total amount previously issued of same series, £1,350.

Birmingham and Midland Tramways, Limited, London, W.C. Trust deed registered June 21 for £200,000 first debenture stock, with power to issue further stock, ranking *pari passu*, up to one-half the subscribed capital. Trustee—Electric and General Investment Company, Limited. A special charge upon certain assets and property, consisting of land at Smethwick, a power-house in course of construction, tramways owned by the company (except those it is under obligation to sell), and securities in certain tramway companies, and the floating charges on all the remaining assets and property, present and future.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Aurelia (Perugia, Italy).—The Municipality require tenders for an electric lighting installation by Aug. 18.

Worksop.—Tenders are to be obtained for cables, etc., for mains, and additional feeder, estimated at £1,000.

Heston and Isleworth—The Council invite tenders for electricity meters. Tenders by July 4. See advertisement in former issue.

Radcliffe.—The surveyor has been instructed to obtain revised tenders from the firms who tendered previously for the special tramway track work.

Rochdale.—Tenders are invited for the supply and laying of high and low tension feeder cables, etc. Tenders by July 5. See advertisement in last issue.

Penrith.—The Council require tenders for oil or gas engines, dynamos, switchboard boosters, storage battery, and mains. Tenders by July 5. See advertisement in former issue.

Kingston-upon-Thames.—The Corporation invite tenders for addition to electric works building. Specification, etc., may be obtained from the Borough Surveyor. Tenders by July 14.

Dublin.—The Electricity Committee invite tenders for the supply of 100,000 pairs of arc lamp carbons. Specifications, etc., may be obtained from Mr. F. J. Allan, secretary. Tenders by July 9.

Batley.—The Corporation invite tenders for one 350-kw. steam dynamo and switchboard extension for same. Specifications, etc., may be obtained from the Borough Electrical Engineer. Tenders by July 16.

Halling (near Rochester).—Tenders are invited for electrical installation at the cement works of Messrs. Wm. Lee, Son, and Co., Limited, Halling. Particulars may be obtained from the Works Manager.

Devonport (Tasmania).—The Town Board invite tenders for the supply and delivery of alternatively 50 or 100 smallest-size meters to read direct in B.O.T. units on 220 volt direct-current circuits. See advertisement.

Priego (Province of Cordova, Spain).—The Municipality require tenders for installation and working until Dec. 31, 1922, of electric lighting. Particulars may be obtained from the Secretary of the above. Tenders by July 10.

Felixstowe.—The Urban District Council invite tenders (Section C) extensions to feeders. Specifications, etc., may be obtained at the offices of Mr. Regina'd P. Wilson, 66, Victoria-street, Westminster. Tenders by 12 noon on July 9.

Glasgow.—The Trustees of the Clyde Navigation invite tenders for two electric 32-ton coaling hoists for Clydebank Dock. Specification, etc., may be obtained from Mr. Geo. H. Baxter, 16, Robertson-street, Glasgow. Tenders by noon on July 25.

Ashton-under-Lyne.—Tenders are invited for lighting by electricity St. Michael's (Parish) Church, Ashton-under-Lyne. Particulars may be obtained from Mr. T. J. Barlow, Athol House, Fraser-street, Ashton-under-Lyne. Tenders by July 7.

Hounslow.—The Heston and Isleworth Urban District Council invite tenders for the supply of electricity meters. Specifications, etc., may be obtained from Messrs. J. and J. S. Enright, 68, Lincoln's-inn-fields, London, W.C. Tenders by July 4.

Whitby.—The Urban District Council invite tenders for (a) distributor and street-lighting cables; (b) network and service-boxes. Specifications, etc., may be obtained from Mr. H. S. King, electrical engineer. Tenders by 10 a.m. on July 18.

Stourbridge.—The Urban District Council invite tenders for the supply and laying of electric mains. Specifications, etc., may be obtained of the Electrical Engineer, Town Hall, Stourbridge. Tenders by noon on July 8. See advertisement in last issue.

Maidstone.—The Electricity Committee of the borough invite tenders for the supply and delivery of coal to their electricity works, Fair Meadow, Maidstone, until June 1, 1905. Specifications, etc., may be obtained from the Borough Electrical Engineer.

Erith.—The Urban District Council invite tenders for (1) rails, fishplates, and bolts; (2) permanent-way construction. Specifications, etc., may be obtained from Mr. C. H. Fry, Council Offices. Tenders by 12 noon on July 11. See advertisement in former issue.

Suakim.—The Public Works Department require tenders for 220 miles of galvanised wire, 1,100 yards ditto, 1,500 screws and bolts, 6,000 insulators, 1,500 creosoted fir telegraph poles, and 3,000 oak poles, to be delivered at Suakim between Oct. 1 and Dec. 1.

Manchester.—The Highways Committee invite tenders for laying underground telephone pipes (Contract No. 10), with other appurtenant works. Specifications, etc., may be obtained at the City Surveyor's Office, Town Hall, Manchester. Tenders by 10 a.m. on July 11.

Aston Manor.—The Corporation invite tenders for the supply, delivery, and erection complete of pipework, etc. Specifications, etc., may be obtained from Mr. T. J. Ballard, Electricity Works, Chester-street, Aston Manor. Tenders before 12 noon on July 28. See advertisement in last issue.

Stepney.—The Electricity Committee invite tenders for the supply during the year of ampere-hour meters, demand indicators, arc lamp carbons. Specifications, etc., may be obtained from Mr. Wm. C. P. Tapper, 27, Osborn-street, Whitechapel, E. Tenders by July 4. See advertisement in last issue.

Middleton (Lancs.).—The Corporation invite tenders for the supply of 3,000 tons of engine coal to be delivered at the Electricity Station, Townley-street, Middleton, during ensuing 12 months. Particulars may be obtained from Mr. S. Pauls, borough electrical engineer. Tenders by July 11.

Leicester.—The Tramways Committee invite tenders for various machine tools to be delivered, erected, and set to work at their Abbey Park-road car depot, and at the fitting shop, power station, Belgrave-road. Particulars may be obtained from Mr. E. George Mawbey, M.I.C.E., Town Hall, Leicester. Tenders by July 5.

St. Pancras.—The Borough Council invite tenders for the supply and erection of main switchboard at the King's-road power-house, Camden Town, N.W. Specifications, etc., may be obtained at the offices of the Electricity Department, 57, Pratt-street, N.W. Tenders by 12 noon on July 19. See advertisement in last issue.

Bridgend.—The Committee of Visitors invite tenders for supply and erection of a complete telephone and fire-alarm installation for the Angelton and Parc Gwyllt Asylums, Bridgend. Specifications, etc., may be obtained from Mr. W. E. R. Allen, Glamorgan County

Digitized by Google

Council Offices, Cardiff. Tenders by noon on July 6. Note.—Tenders already received have not been opened.

Dartford.—The Urban District Council invite tenders for carrying out an extension of underground and pilot cables drawn into existing spareways, and for the laying of private and public lighting cables, together with all necessary roadwork, junction boxes, etc. Specifications, etc., may be obtained from Mr. W. Kay, clerk to the Council. Tenders by 12 noon on the 19th proximo. See advertisement.

Bristol.—The Electrical Committee invite tenders for h.t. switchgear, water-tube boilers, two 1,000-kw. three-phase extra high-tension turbo-alternators, two 500-kw. induction-type motor-generators, e.h.t. to d.c., e.h.t. cables, e.h.t. transformers, e.h.t. switchgear. Specifications, etc., can be obtained from Mr. H. Faraday Proctor, city electrical engineer. Tenders by 10 a.m. on July 15. See advertisement.

Hastings.—The Corporation invite tenders for the supply for their electric light works of about 2,500 tons of best Welsh smokeless steam coal, either Glassbrook Merthyr, smokeless unscreened large coal, Bwllfa No. 1 large smokeless, or Nixon's Navigation large coal, to be delivered within ensuing 12 months. Specifications may be obtained from the Borough Electrical Engineer, Electric Light Works. Tenders by 12 noon on July 5.

Warrington.—The Corporation invite tenders for the supply, delivery, and erection of steel poles, trolley wires, etc., forming complete overhead equipment for about 550 yards of double track, including special arrangements at the swingbridge over the Manchester Ship Canal. Specification, etc., can be obtained at the offices of Messrs. Preece and Cardew, 8, Queen Anne's-gate, Westminster, S.W. Tenders by 12 noon on July 12.

Handsworth.—The Urban District Council invite tenders for the supply and delivery of the following in connection with the electric lighting: (4) water-tube boilers; (5) engines and dynamos; (6) overhead hand travelling crane; (7) storage battery; (8) arc lamps and posts; (9) switchboard and boosters. Specifications, etc., can be obtained from Mr. H. Ward, The Council House, Handsworth, near Birmingham. Tenders by July 11.

Derby.—The Corporation invite tenders for the making, erecting, setting to work, and maintaining in good order for twelve months on the site of the intended pumping station, of various machinery, including an electric light installation, consisting of compound high-speed engine and dynamo and sundry fittings, etc. Specifications, etc., may be obtained at the office of Messrs. James Mansergh and Sons 5, Victoria-street, Westminster. Tenders by noon on July 13.

Rochdale.—The Corporation invite tenders for the supply, delivery, and erection at the Electricity Works, Rochdale, Lancashire, of two steam turbines direct connected to two 3-phase alternators, or alternatively for alternators connected to high-speed triple-expansion engines (Contract No. 7); and also for one motor-driven 3-phase alternator (Contract No. 8). Specifications, etc., may be obtained at the offices of Messrs. Lacey, Sillar, and Leigh, 2, Queen Anne's-gate, Westminster. Tenders by July 18. See advertisement.

St. Marylebone.—The Borough Council invite tenders for supply and erection of constructional steelwork and buildings for their generating station in Richmond-street, Maida Vale, W.; also for steam generating plant, steam turbines, electrical generating plant and cables. Specifications, etc., for constructional steelwork, steam and electrical generating plant and cables, can be obtained at the offices of Mr. Arthur Wright, 30, Moorgate-street, E.C.; and for the buildings from Mr. H. T. A. Chidgey, architect, Charing Cross-chambers, Duke-street, W.C. Tenders before 12 noon on July 6.

Greenwich.—The London County Council invite tenders for the supply, delivery, and erection of three 3-ton electric travelling jib cranes and two electric locomotives upon the wharf of the electricity generating station now being erected by the Council at Greenwich. The jib cranes will be operated by three-phase alternating currents, and the locomotives by direct current. Certain parts of the locomotives—viz., the motors, controllers, wheels, and axles—will be delivered to the contractor by the Council. Specifications, etc., may be obtained at the County Hall, Spring gardens, S.W. Tenders by 10 a.m. on July 12.

Reichenberg (Austria Hungary).—The project for the establishment of a central distributing electric power and light plant in the Reichenberg land district has taken definite form. The territory included is about 10 miles square, and 24 towns and villages have joined in the movement and subscribed to the capital stock. Some 10 more are expected to join. The population of the district, exclusive of Reichenberg, is about 60,000. Stock is subscribed at present to the amount of £40,000, and this it is proposed to increase to £80,000. The principal purpose of the corporation will be the distribution of electric light and power, with the possibility of installing and working a system of suburban electric tramways. Tramway and light franchises for the city of Reichenberg are at present owned by private corporations, and at their expiration it has been generally supposed that the city would take over and conduct the enterprises. Negotiations are pending, however, which may change the situation in this respect. Communications regarding equipment, etc., may be addressed to directors Alfred Ginskey, Maffersdorf, and Dr. Richard Pirkl, Reichenberg.

RESULTS OF TENDERS.

Worksop.—The tender of Scott and Mountain has been accepted or repairs to machinery at £47.

Brighouse.—The Corporation have accepted the tender of W. T. Glover and Co., Manchester, for laying cables in the borough.

Melton Mowbray.—The Urban District Council have accepted the tender of the Electric Light Company, at £325 per annum, for street-lighting for a term of five years.

Cardiff.—The tender of Merrilees, Watson, and Co., Glasgow, at £2,127, has been accepted for the provision of condensing plant at the Canton electric light power station.

Bristol.—The Electrical Committee have accepted the tender of R. Wilkins and Son, Bishop-street, for the construction of switchrooms at the Temple Back electricity works.

Southampton.—The Town Council have accepted the tender of J. R. Wood and Co. for the supply of small coal to the electricity works at 10s. 9d. per ton delivered, for 12 months.

Colchester.—The Corporation have accepted the tender of Marshall and Co., High-road, Leytonstone, E., for the supply and erection of the electric lighting installation at the car depôt and offices.

Stretford (Lancs.).—The Urban District Council have accepted the tender of the Lancashire Dynamo Motor Company, Trafford Park, Manchester, at £2,663, for a 400-kw. set with Belliss and Morcom engine.

Cooling Towers.—Matthews and Yates, Limited, Cyclone Works, Swinton, Manchester, report orders for 9ft. fans from Donat and Co., of Manchester (for the Preston Corporation towers), and from the Klein Engineering Company, Limited (for Calcutta).

London, N.—The tender of C. Ford, Willesden Junction, at nearly £25,000, for power and generating station at Brimsdown, Ponders End, Middlesex, and £30,000 for car-sheds, sub-stations, offices, battery-rooms, etc., in the parishes of Wood Green and Finchley, has been accepted.

London, N.—The Middlesex County Council have accepted the tender of C. Ford, Willesden Junction, at £21,351, for construction of railways No. 16 and 17, including two lines of double tracks, with crossovers and contingent road works, etc., through the grounds of the Alexandra Palace, Hornsey, and Wood Green.

East Barnet Valley.—The Urban District Council have received the following tenders for telephones connecting the police station, fire-station, call boys' residence (East Barnet-road), and captain's residence (Station-road): National Telephone Company, £14 per annum; General Post Office, £13 per annum (accepted).

Bray.—The Urban District Council have received the following tenders for scrap iron at electric light works: Louis Clein, at 28s. per ton mixed metal, 8s. per cwt. old lead, and 3½d. per lb. for copper; McGowan Bros., 38s. per ton iron and metal (accepted); A. Finlay and Co., £5. 10s. for lot; Tonge and Taggart, £5. 10s. for lot.

Switchboards.—Cowans Limited, 82, Victoria-street, S.W., report the following contracts: Ealing—H.T. feeder-board and extension to generator-board; Aston—extra H.T. main switchboard; Cardiff—main L.T. switchboard; Bristol—arc-lighting switchboard; Royal Courts of Justice—main switchboard; Poplar—L.T. switchboards for motor-generators, etc.; Fife—extra H.T. main switchboard.

Belfast.—The Electricity Committee have accepted the following tenders: Lancashire Dynamo Motor Company, for 5 and 7½ h.p. motors; Electromotors, Limited, ½, 1, and 4 h.p. motors; Bruce Peebles and Co., 2, 10, 15, and 25 h.p. motors; British Westinghouse Electric and Manufacturing Company, 3 h.p. motors; Fairbairn, Lawson, Combe, Barbour, Limited, pipework; and M'Dowell, Leathem, and Fraser, gangways.

Hammersmith.—The Council have received the following tenders for two slow speed generating sets, without condensers:

Siemens Bros. and Co., Cole-Marchant-Morley engine (five alternatives)	£20,525
Cole, Marchant, and Morley, E.C.C. alternator	21,026
Electrical Company, Musgrave engine (no condensers)	21,787
British Westinghouse Company, Musgrave engine, Westinghouse alternator (94 revs. per minute)	21,890
Dick, Kerr, and Co., Musgrave engine (one alternative)	22,194
General Electric Company (less £2 106 for condensing plant)	22,458
Wallsend Slipway Company, Musgrave engine, G.E.C. alternator	22,710
Mather and Platt, Wallsend engine	22,864
Electric Construction Co. (less £2,430 for condensing plant)	23 355
Combe, Barbour, and Co., Mather and Platt alternator	24,231
Witting, Eborall, and Co. (less £2,070 for condensing plant)	25,270
Musgrave and Co., Musgrave engine, Siemens alternator (including £2,277 for condensing plant, three alternatives)	25 628
D. Stewart and Co. (incomplete)	25,899
Labmeyer Electric Company, Musgrave engine (including £2,311 for condensing plant)	25,266

For steam turbines.

	Two turbines.	Condenser plant.	Exciters.
Willans and Robinson	£12,008	£2,446	£1,046
Ditto	12,008	3,104	1,046
Bruce Peebles and Co.	12 838	2,416	965
Siemens Bros. and Co.	13,155	2,492	1,031
Howdens	13,500	2,500	1,130
Richardson, Westgarth, and Co.	14 540	3 200	967
British Thomson-Houston Co.	14,545	2 072	740
Ditto (alternative)	14,545	2 814	740
Ditto (alternative)	14,545	3 251	740
Brush Company	15,000	2,110	619
C. A. Parsons and Co.	15,050	2,416	890
British Westinghouse Co.	15,186	2,512	772

Accepted tenders: Richardson, Westgarth, and Co., one turbo-generator £7,270, two condensers £3,200; British Thomson-Houston Company, one turbo-generator £7,272. 10s., exciter plant £740.

Wigan.—The Corporation have received the following tenders for 12 bogie cars, single-deck, two-motor equipment: British Westinghouse Manufacturing Company, Manchester (accepted); Dick, Kerr, and Co., Preston; Hurst, Nelson, and Co., Glasgow; British Thomson-Houston

Digitized by Google

Company, Rugby; Brush Electrical Engineering Company, Loughborough; Witting, Eborall, and Co., London; International Electric Company, London.

Chesterfield.—The Town Council have accepted the following tenders: British Insulated and Helsby Cables, Limited, at £41,257. 15s 4d., to completely equip the permanent way, overhead electric lines, underground feeders, etc., of the 3½ miles of tramways sanctioned by the new Improvement Act; British Westinghouse Company, at £2,640, to electrically equip the cars; Brush Electrical Engineering Company, at £3,960, to supply the necessary car bodies.

Exeter.—The following tenders have been received for the tramways:

No. 1.—Permanent way, paving, and bonding.

No. 2.—Overhead equipment.

British Thomson-Houston, Spencer poles, weight 877/1275, Brooklyn strains 7,500, £3,180. 5s. 3d., circular bases 18s. 6d., oval bases £1. 8s. 6d., rosettes £2. 15s., side guard wires £2. 18s., centre guard wires £5. 17s. 6d., rosettes £3. 2s. 6d.

R. W. Blackwell and Co., Spencer or Stewart and Lloyds poles, weight 730/1100, Brooklyn strains 16,641, £3,286. 0s. 2d., circular bases £1. 1s. 10d., oval bases £3 5s. and £3. 15s., rosettes £4. 5s. 10d., side guard wires £3. 6s. 3d., centre guard wires £4. 6s. 3d., rosettes £7. 2s. 1d.

Brush Company, Spencer poles, weight 870/1270, Brooklyn strains 7,000, £3,305. 12s. 4d., circular bases £1, oval bases £3, rosettes £2. 10s., side guard wires £2. 10s., centre guard wires £2. 10s., rosettes £2. 10s.

Griffiths (no particulars), £3,387. 15s. 6d., circular bases £1, oval bases £3, rosettes £2. 10s., side guard wires £2. 10s., centre guard wires £2. 10s., rosettes £2. 10s.

J. G. White and Co., Spencer poles, weight 820.1230, Brooklyn strains 4,480 (?), £3 437. 7s. 7d., circular bases 18s. 6d., oval bases £1. 15s., rosettes £4. 6s. 4d., side guard wires £2. 13s. 9d., centre guard wires £3. 19s., rosettes £11. 9s.

British Electric Equipment Company, Spencer poles, weight 877/1275, £3,511. 4s. 8d., circular bases £1. 8s. 8d., oval bases £6. 1s., rosettes £4. 10s. 8d., side guard wires £2. 16s. 3d., centre guard wires £5. 5s. 6d., rosettes £7. 12s.

Law, Spencer poles, weight 877/1275, £3,511. 4s. 8d., circular bases £1. 8s. 8d., oval bases £6. 1s., rosettes £4. 10s. 8d., side guard wires £2. 16s. 3d., centre guard wires £5. 5s. 6d., rosettes £7. 12s.

Dick, Kerr, and Co., approved poles, weight 877/1275, approved strains, £3,641. 5s. 5d., circular bases £1. 1s., oval bases £3, rosettes £3. 19s., side guard wires £3, centre guard wires £4. 7s. 9d., rosettes £4. 7s. 9d. (accepted).

British Insulated Wire Company, Spencer poles, weight 877/1275, Brooklyn strains 5,500, £3,659. 9s. 10d., circular bases £1. 2s. 9d., oval bases £3 2s. 6d., rosettes £3. 7s. 2d., side guard wires £3, centre guard wires £6, rosettes £3. 12s. 6d.

British Insulated Wire Company, £3,713. 17s. 10d.

Underwoods, Spencer poles, weight 877/1275, £3,899. 17s. 6d., circular bases £2. 2s., oval bases £3. 10s. 6d., rosettes £1. 10s., side guard wires, £6, centre guard wires, £9, rosettes £7. 10s.

Macartney, McElroy, and Co., Spencer, Stewart, and Lloyd, or Russell poles, weight 877/1275, approved strains, £3,926. 16s. 4d., circular bases £1. 8s. 1d., oval bases £7. 10s., rosettes £1. 11s. 3d., side guard wires £1. 10s. 4d., centre guard wires £3. 2s. 6d., rosettes £1. 17s. 6d.

Willey and Co., approved British poles, weight 877/1275, approved strains, £4,053, circular bases £1. 7s. 6d., oval bases £3. 10s., rosettes £3. 10s., side guards wires £1. 10s., centre guard wires £4, rosettes £3. 10s.

British Westinghouse Company (see Willey and Co.'s tender), £4,294. 5s. 6d., circular bases £1. 8s. 6d., oval bases £3. 13s. 6d., rosettes £3. 13s. 6d., side guard wires £1. 11s. 6d., centre guard wires £4. 4s., rosettes £3 13s. 6d.

Hill and Co., weight 877/1275, Brooklyn strains 8,000, £4,515. 14s. 2½d., circular bases £1. 6s. 6d., oval bases £5. 12s. 6d., rosettes £3. 2s. 6d., side guard wires £1. 10s., centre guard wires £3, rosettes £2. 10s.

No. 3.—Feeder Cables, etc.

Western Electric Company, di-electric paper, ducts fibre, £2,695. 1s. 4d., maintenance rate 1 per cent. on £1,662. 5s. 6d., time required six weeks.

Western Electric Company, di-electric paper, ducts Suttons, £2,716. 10s. 6d.

British Electric Equipment Company, di-electric and ducts (maker not given), £2,749. 12s. 10d., maintenance rate 2 p.c. on invoice price.

St. Helen's Cable Company, di-electric paper, ducts Stanley, £2,756. 15s. 11d., maintenance rate 2 p.c. on £1,650, time required 12 weeks, arbitration clause essential.

St. Helen's Cable Company, di-electric dialite without lead, £2,582. 16s. 4d., not to specification.

J. G. White and Co., di-electric paper, ducts Suttons, £2,841. 16s., maintenance rate 1 per cent. on £1,750, time required three months.

Siemens Bros., di-electric paper, ducts Suttons, £2,860. 14s 8d., maintenance rate 1 per cent. on £1,783. 8s. 10d., time required four months, arbitration clause suggested.

Dick, Kerr, and Co., di-electric paper, ducts Suttons, £2,897. 12s. 10d., maintenance rate 1½ per cent. on £1,810. 4s., time required three months (accepted).

British Insulated and Helsby Cable Company, di-electric paper, ducts Suttons, £2,917. 6s. 7d., maintenance rate, 1½ per cent. on £1,765, time required 14 weeks, arbitration clause asked for.

British Insulated and Helsby Cable Company, di-electric paper, ducts fibre, £2,878. 7s. 5d., prices subject to rise of metal.

W. T. Glover and Co., di-electric diatrice paper, ducts approved, £2,948. 6s. 8d., 1½ per cent. on total invoice value of contract, time required four months, arbitration clause asked for.

W. T. Glover and Co., ducts fibre, £2,894. 11s. 8d., arbitration clause asked for.

Underwood, di-electric paper (Siemens), ducts Suttons, £2,970. 19s. 10d., maintenance rate 1 per cent. on £1,950, time required six months, arbitration clause asked for.

W. T. Henley's Works, di-electric paper, ducts Albion clay, £2,973. 18s. 10d., maintenance rate 1½ per cent. on £1 973. 18s. 10d., time required 12 weeks, forms of tender not filled in or signed.

Willey and Co. (see Westinghouse tender), £3,009.

British Westinghouse Company, di-electric paper, ducts approved British make, £3,009. 5s. 11d., maintenance rate 1 per cent. on £1,783. 10s., specified time.

Callender's Cable Company, di-electric paper, ducts Albion clay or Doulton, £3,059. 18s., maintenance rate 5 per cent. on total price, time required four months or less, arbitration and electrolysis clauses.

Griffiths Bros., di-electric (as Callender's), £3 059. 18s., maintenance rate 5 per cent. as above, time required four months, conditional on acceptance of tender for contract No. 1.

Johnson and Phillips, di-electric paper (no Sutton's bitumen), £3.211. 19s. 11d., first year 1½ per cent. on £1,660, second year 2½ per cent., after 5 per cent., time required four months.

Macartney, McElroy, and Co., di-electric, Johnson's, Phillips, Glover, or other approved, £3,630. 19s. 3d., maintenance rate 1½ per cent. on £2,973. 18s. 10d.

No. 4.—Double-Decked Motorcars.

Willey and Co. (particulars as per Westinghouse tender), £6,701.

British Westinghouse Company, car bodies Electric Railway and Tramway Car Works or Brush, trucks Brill £52. 6s., Brush £52s. 6s., Peckham £52. 6s., motors Westinghouse No. 46, controllers 9 O.M., notches 8 power, 7 brake, £6 701. 17s. 7d., extra for steel tyres £126, extra for magnetic brakes £384 (Newell), extras—folding steps "Leicester" type £96. 12s., E. R. and T. C. Works type £55. 4s.

Fisher Bros., car bodies Plymouth Wagon Works, trucks Brill 21E £64, Peckham £80 motors B.T.H., controllors B.T.H., notches 8 power, 5 brake, £6 738. 11s., extra for steel tyres £72, extra for magnetic brakes £720 (?). Rates and details omitted. Body has reversed stairway, which is not in accordance with specification.

Dick, Kerr, and Co., car bodies Dick, Kerr, trucks Brill 21E only, motors DK 6A, controllers DB 1E, notches 7 power, 5 brake, £6,933. 16s. 8d., extra for steel tyres £114, extra for magnetic brakes £360 (?) Motor details incomplete. Steel tyred wheels 31½in. (accepted).

Brush Electric Engineering Company, car bodies Brush, trucks Brush, Brill interchangeable with Brill 21E £50, £7,176, extra for steel tyres £108, extra for magnetic brakes £300 B.T.H., £480 Newell. Extra for B.T.H. equipment £144.

Witting, Eborall and Co., car bodies Brush, trucks Brill 21E £71 10s., Brush £69, motors W and E. T 1 V (and 1850 DBP), controllers own type magnetic blow out, notches 5 brake, £7,361, extra for steel tyres £108. One-set Commutator tools and spanners £7.

British Thomson-Houston Company, car bodies Brush, trucks Brill £64, Brush £55. 10s., motors GE 58/6 turn (1540 DBP), controllers B 18, notches 2 running, 6 resistance, 6 brake, £7 386. 11s. 6d., extra for steel tyres £108, extra for magnetic brake £225 (B.T.H.) on Brill trucks, £276 (B.T.H.) on Brush trucks. Do not recommend electric skotch.

J. G. White and Co., car bodies Dick, Kerr, trucks Brill £64 only, motors Dick-Kerr Equipment, £7 482. 2s. 5d., extra for steel tyres £120, extra for magnetic brakes £336 (B.T.H.).

Parliament.—The following Bills have been read a third time in the House of Lords: Bristol Tramways (Extension), Baker-street and Waterloo Railway, Manchester Corporation Tramways, L. and N.W. Railway, Harrow-road and Paddington Tramways. In the House of Commons, Lancashire Electric Power. The Duke of Northumberland's Committee have refused to allow the Doncaster Corporation to extend their area, and have struck out the electricity portion of the Bill altogether. The preamble has been found proved of the Electric Lighting of London Bill, in which the Board of Trade seek to adjust the area of supply for electricity of the various local authorities and companies in London.

BUSINESS NOTES.

TRACTION.

Leeds.—A further conference is to be held with the employés on the question of "split turns."

Bury, Rochdale, and Oldham Tramways.—The arbitration proceedings have been completed.

Glasgow Tramway and Omnibus Co.—The reconstruction of this concern has been decided upon.

Blackpool.—The latest returns of the Corporation tramways show substantial increases over last year.

Preston.—Further branches of the tramways will be inspected by the Board of Trade in a day or two.

Wicklow.—An enquiry has been held by the Board of Works into the tramway proposed by Lord Fitzwilliam.

Harrow and Uxbridge Railway.—This new line was formally opened yesterday, and will be ready for traffic on Monday.

Wigan.—Rapid progress is being made in the laying of the broad gauge lines on the Platt Bridge route of the Wigan Corporation tramway system.

Chesterfield.—A special meeting has been convened to consider tenders for the electrification of the tramways and an extension to Whittington Moor.

Harrogate.—The National Telephone Company has withdrawn its opposition to the passing of the Harrogate Tramroads Bill through committee of the House of Commons.

Poole.—Further evidence has been taken in connection with the arbitration between the company and the Bournemouth Corporation in relation to the sale of the company's undertaking.

Bury.—Work on the Manchester-road section is being pushed on very rapidly, and there is a good prospect of the reconstruction being carried out considerably earlier than was expected.

Erith.—A proposition that the tramway scheme should not be proceeded with, owing to industrial depression, was defeated by a large majority, only the mover and seconder voting for it.

Metropolitan Electric Tramways, Limited.—The electrification of these tramways is now approaching completion. It is expected that the Board of Trade inspection will take place in a few days.

Southend.—The tram receipts during the last three months show an increase of almost 2d. per car mile over the receipts for the corresponding period last year, and 64,094 more passengers were carried.

Bills in Parliament.—In the House of Lords the following Bills have been read a third time: Bristol Tramways (Extension), Baker-street and Waterloo Railway, and Manchester Corporation Tramways.

Dundee.—At a meeting of the Tramways Committee the engineer was asked to bring forward his scheme for motive power charges at a future date, giving the members fuller details and longer time to consider the matter.

Portsmouth.—Some of the cars have been fitted with small brushes fixed on the truck between the wheels so that they just touch the lines and sweep away the dust which collects in windy weather, the collection of dust having given considerable trouble.

Leicester.—The traffic returns having exceeded expectations, the Tramways Committee recommend that an order be placed with Messrs. Dick, Kerr, and Co. for 40 additional cars at £510 each. Additional shed and office accommodation is also required.

Pontypridd.—The District Council have accepted the tender of the British Thomson-Houston Company for the supply of tramcars, and in the event of Milne bodies and trucks being unobtainable, Brush car bodies and Brill trucks are to be substituted for them.

Rochford.—The District Council have approved the plans of the generating station and car-shed for the Canvey Island tramway, but have deferred their consent to the plan of the track, as further details are required, the track crossing the Council's road near Leigh Beck.

Cape Electric Tramways Co.—An interim dividend of 5 per cent., free of income tax, has been declared, payable to shareholders registered on July 6 and to the holders of Coupon No. 7 attached to warrants to bearer. The transfer register will be closed from July 6 to July 12 inclusive.

Southampton.—At the last meeting of the Council it was stated that there was a slight improvement in the traffic on the Hampton Park section during the fine weather, and that the committee had decided to continue to run the cars there in the hope that the improvement would be maintained.

Llanelly.—The long-deferred scheme of electric traction was discussed at a committee of the Borough Council last Friday. It was decided to appoint a deputation, consisting of the chairman and the vice-chairman, to wait upon the wire company to see what the intentions of the latter were.

Bradford.—At the meeting of the Tramways Committee on Monday a deputation of ratepayers from Bolton Woods and Windhill attended for the purpose of urging upon the committee the necessity of the construction of a tramway route along Canal-road. The committee promised to consider the matter.

Proposed Light Railway.—Public meetings have been held at which resolutions were passed in support of the construction of a light railway from Haverfordwest to St. David's. A similar proposition was made some time ago. The length of the proposed service is about 26 miles, and the estimated cost £130,000.

Cleckheaton.—At a meeting of the General Purposes Committee of the District Council a letter was read from the Board of Trade stating that an order had been forwarded to the Electric Traction Company extending until June 22, 1905, the time for completing the railways authorised by the Spen Valley Light Railways (Extension) Order, 1901.

Shipley.—Complaints have been made to the District Council of the inconvenience caused by the discontinuance of the through service from Thackley to Nab Wood. It appears, however, that this method of working the Shipley traffic does not pay, but a quick and cheap through service from Shipley to Bradford has been provided.

Exeter.—The City Council have awarded the contract for the electric tramways to Messrs. Dick, Kerr, and Co., whose tender was £42,055. The work will commence at once. The first section of the line will be laid throughout the main streets, and the total length is 5½ miles. It is hoped to have the work completed by November.

Christchurch (New Zealand).—The New Zealand Electrical Construction Company, Christchurch, have received intimation that the first shipment of rails for the electric tramways for this city will be shipped from New York in May, and should arrive there about the third week in July, when a start will be made with the laying of the rails.

Birmingham.—The Birmingham Tramways Company have adopted a method for inducing their employés to deal expeditiously with breakages of electric wires. The men on the electric cars have been trained to remedy defects of this kind, prizes being offered every three months. The record in quick time is credited to a man who satisfactorily mended such a breakage in 16 seconds.

Camberwell.—The Borough Council having received from the Board of Trade a copy of Colonel Yorke's report upon the London, Camberwell, and Dulwich tramlines, recommending that they be removed in the interests of public safety, as they had deteriorated so much as to be useless, a recommendation was submitted at Wednesday's meeting of the Council that the Board of Trade be asked to sanction the removal of the lines.

Blaydon.—The Parliamentary Committee of the Whickham Council and a committee of the Blaydon Council have decided to ask the County of Durham Electrical Power Distribution Company to meet the two committees at Blaydon for the purpose of discussing the possibility of establishing a tram service from Dunston to Blaydon. Plans have been prepared by the surveyor to each Council showing the proposed route for such a service.

Beckenham.—The British Electric Traction Company have written to the Urban District Council suggesting that, owing to the lack of unanimity in regard to the tramways proposed to be constructed through the district, the agreement between the company and the Council providing for the construction and leasing of the lines should be cancelled. A motion to this effect was submitted at the last meeting of the Council, but was defeated by one vote.

Wolverhampton.—Colonel Yorke, on behalf of the Board of Trade, inspected the new tramway section constructed from the centre of the town to Heath Town, a distance of 1½ miles, on the 22nd ult. He was so satisfied with the way the work was done and the smooth running of the cars that he passed it for traffic at once. The section is on the Lorain surface system. A quick service of cars was then put on the line, and during the evening 1,400 passengers were carried.

Ayr.—Intimation has reached Ayr from London that at the hearing of the application of the Ayr Corporation in connection with the proposed tramways order the chairman, after discussion, decided that the general orders are not to be dispensed with in respect of tramways Nos. 1, 2, 3, and 4, and the promoters not having complied with these the numbers referred to have been struck out. This means that the proposed extension from Prestwick Cross to Monkton has been disallowed.

Salford.—The Corporation have commenced the work of relaying the lines between the Unsworth boundary and the present terminus of their system at Whitefield railway station. When this is completed the lines will be laid down Radcliffe New-road as far as Dales-lane, where Radcliffe will eventually be coupled up, and then the men will be transferred to Besses, where they will commence work on Bury Old-road and connect the existing system with the Cheetham Hill and Heaton Park lines.

Batheaston.—At its last meeting the Somerset County Council considered an application from the Bath Electric Tramways Company for leave to construct a new loop line at Batheaston, and several petitions against it. It was decided to refuse consent. With reference to the extension of the Bristol tramways, the County Works Committee recommended that a special committee be appointed to confer with the county surveyor and take such action as they might deem necessary as the roads in Long Ashton and Keynsham were likely to be seriously affected by the scheme.

Southport and Lytham Tramways.—The Southport and Lytham Tramway (Extension of Time) Bill, to secure an extension of the time allowed for the construction of the tramway until 1907, came before a committee of the House of Commons as an unopposed Bill. It was stated that all the land required had now been obtained by the company, and the capital for the first portion of the work had been raised. The promoters were now proposing to carry out the scheme forthwith. The Southport Corporation consented to the proposals of the company. The Bill was ordered to be reported for third reading.

Hanley.—Residents have petitioned the Council to bring pressure to bear upon the Potteries Electric Traction Company, Limited, to extend their line now in course of construction to Providence-square. The Council will recommend the company to extend the line to the borough boundary. At a meeting of the General Purposes Committee a letter was read from the secretary of the company stating that he would submit the suggestion from the Council in regard to contract tickets at the next meeting of the Board, but it was improbable that the request could be granted, as the fares were already very low.

Sheffield.—The receipts for the quarter just ended amounted to £60,336, 19s. 9½d. Although this is not the largest amount yet

Digitized by Google

received—it is nearly £1,000 less than the total for the third quarter last year—it is satisfactory to note that the decline recorded in the last quarter of 1903 and the first quarter of this year has been checked. The income for the 13 weeks is over £5,000 more than the quarter ended March 31 this year, and £3,000 increase over the takings for the corresponding quarter last year. The takings during Whit week were over £5,000, and the average per week for the quarter was nearly £4,642.

Tottenham.—In connection with the approaching service of electric cars in the populous districts of Tottenham, Wood Green, and Edmonton, it is interesting to note that the power by which the cars will be worked is transmitted over a great distance from the modern power station recently erected by the North Metropolitan Electric Power Supply Company on the banks of the River Lea at Brimsdown, Enfield. The pressure adopted is 11,000 volts at Brimsdown. The energy is conveyed by a duplicate system of high-tension mains laid underground, which are tested up to 20,000 volts. This is reduced at various sub-stations in the tramway area to 500 volts continuous current. The pressure transmission is presumably the highest in this country for tramway purposes.

Tarporley Light Railway.—At the meeting of the Northwich Rural Council a letter was received from the County Council stating that the plans of the proposed Tarporley light railway had received the consideration of the county surveyor, who had reported to the Main Road and Bridges Committee that they did not effect any main roads either in the urban or rural districts. The surveyor pointed out, however, that the plans contemplated raising the level of the highway between Delamere and Winsford, so as to make the gradient of approaches 1 in 20. As that highway was of some considerable importance, the county surveyor suggested that such approaches should not be of less gradient than 1 in 30, and should have a width between the fences and the bridge of 36ft. The Northwich Council have referred the matter to their Highways Committee.

Dewsbury and Ossett.—The approval by the Select Committee of the House of Lords of the tramway schemes promoted by the Corporations of Dewsbury and Ossett and the Soothill Nether District Council has given great satisfaction to the residents in the districts concerned. With the exception of Soothill and Ossett, all the townships in this district are now connected by tramways. Two years ago the Wakefield District Light Railways Company sought powers to construct a line from Wakefield to Dewsbury along the main road. This scheme was rejected, but the company obtained powers to make a line to Ossett from Wakefield *vid* Horbury. A second effort was made last year to secure running powers into Dewsbury, but it was not successful. The Dewsbury and Ossett Corporations and the Soothill Nether District Council then took the question up, and decided to apply for powers to carry out a joint undertaking.

Belfast.—An enquiry was submitted to the Chief Secretary for Ireland as to whether his attention had been called to a meeting of the Law Committee of the Belfast City Council with representatives of the Belfast and County Down Railway Company, with regard to the Belfast Tramway Bill now before Parliament, at which an agreement was arrived at which, if carried out, will place a monopoly of the passenger traffic of an extended area on the County Down side of Belfast in the hands of the County Down Railway Company, and prevent that whole district from being opened up by the Belfast City Council's tramways; and if so whether, in view of the principles involved in this arrangement, he would take steps to secure its exclusion from the Bill when it comes before the House of Commons for further consideration. Mr. Wyndham replied that the Bill was a private one, not calling for the intervention of the Government.

Bath.—A report was presented at the last meeting of the Town Council in connection with the widening at Odd Down necessitated by the electric tramway route. Having been unable by agreement to obtain possession of the land required by them on satisfactory terms, the tramway company had deposited £292. 6s. (the sum named by a Board of Trade valuer). The company having also given the necessary bond, the land had been pegged out, and the work necessary for the widening of the road commenced. A dispute having arisen as to the nature of the fence to be erected, the Board of Trade had appointed Colonel Sir Colin Scott Moncrieff, R.E., to arbitrate upon the question. Subsequently the owner expressed his willingness to accept a payment of £150 towards the cost of erection of the fence, leaving him to erect the fence at his own expense and to his own satisfaction. The hope was expressed that the matter would be arranged amicably, so as to avoid litigation.

Metropolitan District Railway.—The omnibus Bill promoted by the Metropolitan District Railway came before a Select Committee of the House of Commons on Wednesday. The Bill has already passed the House of Lords. Mr. Freeman, K.C., stated that the Bill asked for an extension of time until 1908 for the completion of the deep-level line between Earl's Court and the Mansion House. Until the completion of the electrification of the District Railway it would be difficult to know exactly what would be the effect on the deep-level line. With regard to the application of the London County Council for the provision of workmen's trains on the new line, Mr. Freeman said that the deep-level line was not calculated or intended to convey workmen; it was for running an express service with few stoppages. The Bill further proposes a revision of fares, the zone system being desired. It is also proposed to restrict the amount of luggage to be allowed each passenger to 28lb. The Bill is opposed by the London County Council and the Fulham Borough Council.

Wellington (New Zealand).—The contractors for the construction of the Wellington tramways (Messrs. M'Elroy, Macartney, and Co.) have received a demand from the Government for the payment of 1s. per cent. upon the capital of the company. The tax is being made upon all persons or firms from outside the colony entering upon a contract to do certain works in New Zealand. The *New Zealand Times* states that there is a probability of the claim being contested on the ground that the New Zealand Government is levying the tax on the whole capital of the company, including that part employed in the progress of works at Durban, Malta, and other parts of the world. This, they claim, does not represent the standing capital of the company, and it is not a fair computation upon which to base such a claim. All the papers in connection with the demand have been forwarded to the head office of the firm in London for their decision. It is understood the contractors for the Auckland tramways (Messrs. White and Co.) are also making a request for a readjustment of their claim on similar grounds.

Norwich.—At its last meeting the Town Council considered the recommendation of the General Purposes Committee that the vacant land at Orford-place be purchased from the New General Traction Company, Limited, and the Norwich Electric Tramways Company for £2,000, the Corporation consenting to the company advertising on the tramway cars during the unexpired portion of the term of 50 years specified in Section 40 of the Norwich Electric Tramways Act, 1897, the Norwich Electric Tramways Company paying to the Corporation 25 per cent. of the gross receipts receivable in respect of such advertisements up to £600, and half of any such gross receipts over and above £600. In the event of the Corporation desiring to purchase the undertaking of the Norwich Electric Tramways Company, on giving notice of such of their intention, the receipts in respect of advertisements are not to be taken into account in ascertaining the then value of the undertaking. An amendment was moved that the term of the arrangement in regard to advertising should be restricted to 10 years, and subject to this the proposition was adopted.

Tipton.—At the meeting of the District Council a letter was read from the South Staffordshire Tramway (Lessee) Company stating that they had received a report from their mining engineer in reference to the subsidences of the road from Dudley to Wednesbury, which was of an unfavourable character. They called attention to the fact that when the Bloomfield Ironworks were offered for sale reference was made to the mining rights, and that if the new owners availed themselves of these rights further subsidences would take place. In the event of the electrification of the line being proceeded with, the deflections of the line would cause a leakage of electricity at the joints. Under the circumstances, the directors of the company were not able to proceed with the electrification of the line as requested by the committee. A further communication was received from the company inviting a deputation from the public authorities concerned to meet representatives of the company at Birmingham. The opinion was expressed that the company were endeavouring to evade their responsibilities, and it was resolved to take immediate action for a conference between the local authorities.

Aston.—The official inspection of the first completed length of the Aston tramways from the city boundary to Aston Cross was held on the 22nd ult. by Colonel Yorke on behalf of the Board of Trade. There were also present Mr. Trotter, electrical expert to the Board of Trade; the Mayor of Aston; Mr. Ballard, borough electrical engineer; Mr. Robert Green, consulting tramway engineer to the Council, and many others. The City of Birmingham Tramways Company was represented by Messrs. Connaty, Barling, R. H. Dickinson, and Pinkerton. A special car had been provided for the trial trip, and the inspection passed off without a hitch of any sort. On the following day an inspection was held of the Cotteridge section, which is leased to the British Electric Traction Company. From the point whence it leaves the Bristol-road line to the terminus, the new branch measures three miles, and is a single line with occasional loop crossings. Provision is made at the depôt for eight cars, and the total cost of constructing the line has been between £30,000 and £40,000. The lease granted to the company will expire at the same time as that for the Bristol-road route in 1911. The trial trip passed off smoothly, and Colonel Yorke expressed his satisfaction with the arrangements generally.

North-Eastern Railway.—Commencing to-day, a complete service of electric trains is to be run on the 37 miles of railway in the neighbourhood of Newcastle, upon the conversion of which from steam to electric traction the North-Eastern Railway Company have been engaged for the past 18 months. Sir George Gibb has thus fulfilled the promise he gave when the first section of these lines was opened for electric working that the whole work should be completed by June 30. In the time-tables of the company for July to September, which have just been published, 4½ pages are occupied by the electric trains. There is to be a circular service running every half hour between Newcastle (Central) and Newcastle (New Bridge-street) *via* Wallsend, Tynemouth, and Monkseaton, in addition to the local services between the Central Station, Newcastle, and Monkseaton, and between Benton and New Bridge-street, Newcastle. Then hourly trains are to be run by electricity between Newcastle (Central) and Tynemouth over the Riverside branch, and, further, there is to be a service of express electric trains between Newcastle and Monkseaton, Whitley Bay, and Tynemouth *via* Backworth, covering the journey to the coast in 20 minutes. Doubtless the trains will be made more frequent as matters progress. The electrification has been accomplished with a celerity that reflects great credit upon the company and the contractors.

Newcastle.—A deputation consisting of the members for Newcastle-on-Tyne and several parliamentary friends who support their views had an interview with the President of the Board of Trade and Mr. Bonar Law on the inter-running question, and expressed the opinion that compulsory running powers were undesirable. Mr. Gerald Balfour made a non-committal reply, and it is understood that the Government will maintain a neutral attitude. A number of new double-decker cars have been placed on the Osborne-road and Elswick sections of the Corporation electric tramway system. The inside arrangement is altogether different from the older cars, the garden seats of the larger bogie cars being adopted. The seats are placed four single at each entrance to the car, and eight double in the body of the coach, this arrangement affording better facilities for ingress and egress. Ten

Digitized by Google

passengers are also allowed to stand inside. Outside 34 passengers can be seated, the cars being constructed to carry 68 persons. The protecting rail round the top of the car has been raised considerably. During race week the Newcastle tramcars carried 990,067 passengers, ran 94,190 miles, and earned £4,988 in fares, the average receipts per car mile being 12·71d. These returns show an increase on the returns of race week last year of 117,602 passengers, 9,120 miles, £656 in fares, and ·49d. per car mile. A new record for one week's traffic is thus established.

Manchester.—The report for the year ended March 25 shows a total revenue of £611,881. When the last annual report (March, 1903) was presented the routes open for traffic aggregated nearly 78 miles of single track. During the past 12 months, however, an additional length of nearly 60 miles has been opened, thus bringing the aggregate length of single track to about 138 miles (137 miles 1,602 yards). The working expenses were £392,504. This left a balance which, with bank interest, make a total profit of £222,456, against £126,566 last year. A sum of £50,000 was paid in relief of the rates, £52,000 for interest on mortgage debt, £27,000 for redemption of debt, £70,000 went to reserve, renewals, and depreciation, £20,000 in rent charges, and £2 012 for street improvements round the infirmary. In the year 1903-4 the cost of electrical energy per car per mile was 1·84d., as against 1·94d. in 1902-3; and the salaries, wages of drivers, guards, and traffic staff 2·35d., as compared with 2·27d. in the previous year. The total traffic expenses were 3·41d. per car mile, against 3·53d. in 1902-3, and the total management expenses ·67d., against ·75d. Repairs and maintenance cost ·86d. per car mile, as compared with ·73d. in the previous 12 months. The total operating expenses were 6·78d. per car mile last year, compared with 6·95d. in 1902-3. The total number of passengers was 120,772,368. The average traffic revenue per car mile was 10·52d., the average traffic revenue per mile of single track £4,468, and the average total revenue per car mile 10·67d. The working expense per car mile, excluding power cost, was 4·94d., while including power cost it was 6·78d. The average fare paid per passenger was 1·2d., the average number of passengers per car mile was nine, and the average number of journeys per head of the population per annum was 161. The electrical energy used amounted to 16,815,764 units, the number of units per car mile being 1·23. The percentage of working expenses to receipts was 64. The total borrowing powers of the department stand at £1,805,500. Of this sum £1,505 668 has been taken up. The gross capital expenditure to date is £1,485,162.

Aberdeen.—The official statement of the Corporation tramway accounts has just been issued, and shows highly favourable results. The revenue amounts to £64,071. 9s. 9d., as compared with £50,986. 0s. 7d., an increase of £14,085. 9s. 2d. over the revenue of the previous year. The total is made up thus: passenger fares, £63.246. 2s. 8d., representing 15,538,167 passengers, as against 12,152,774 passengers last year; advertising on cars, £552; and rents and miscellaneous receipts, £273. 7s. 1d. The average income per mile was 11·14d. The working expenses total £38 997. 0s. 3d., compared with £27,571. 4s. 6d. last year, leaving a profit on the actual working of £25,074. 9s. 6d. to be carried to the net revenue account. The working expenses include: traffic expenses, £16,810. 11s. 7d. (2·929d. per mile); electric current, £9,626. 9s. 6d. (1·675d. per mile); maintenance and repairs, £6,677. 13s. 8d. (1·162d. per mile); general charges, £3,939. 18s. 7d. (·680d. per mile); and depreciation on cars, plant, office furniture, and buildings, £1,942. 6s. 11d. (·338d. per mile). The average working expenses per mile work out at 6·78d. The balance of £25,074d. 9s. 6d., carried to net revenue account, is disposed of thus: interest on mortgages and loans, bank interest, and commissions and stamp duty, £9,449. 13s. 11d. (last year £7,666. 8s. 8d.); amount written off preliminary and parliamentary expenses, £889. 7s. 6d. (last year, £734. 3s. 4d.); carried to credit of sinking fund, £2,396. 8s. 10d. (last year, £1,884. 5s. 2d.); carried to credit of renewal account, £8,000 (last year £8,458. 18s. 9d.); capital account written off value of buildings, £4 288. 19s. 3d. The length of the system is: double track, 11 miles 3 furlongs 114 yards; single track, 2 miles 5 furlongs 140 yards; length of street in which tramways are laid, 14 miles 1 furlong 34 yards; total length of single track, 25 miles 4 furlongs 148 yards; depôt lines, 7 yards; crossings and sidings, 151 yards. The best week was that ending July 25 last, when £1,597. 7s. 6d. was drawn, representing 356,810 passengers. In the previous year the high-water mark was reached in the week during which the Highland and Agricultural Society show was held on the Links, when £1,647 16s. 1d. was drawn, representing 380,958 passengers carried. The Corporation have resolved to run, as an experiment, a service of cars for the convenience of workmen in the early morning, the fare to be 1d. on each route, except where the ½d. rate at present exists. In order to meet the convenience of the public three cars were run on Sunday by the Suburban Tramways Company on the new route between Mannofield and Bieldside, one of them being provided with the new covered top. The service was one of 20 minutes, starting from Bieldside at 10 o'clock and stopping at 10 o'clock at night. Two of the cars were run all the way between Castle-street and Bieldside, and the third was kept between Mannofield and Bieldside, being fed by the Corporation cars. The service was popular beyond all expectation, and thousands of intending passengers could not be accommodated. A time-table will be issued by the company this week.

London County Council.—The motion, of which notice had been given, to refer to the Improvements Committee a proposal for the acquisition by the Council of Hungerford Bridge and Charing Cross railway station, and constructing a new road bridge with a double tramway line, has been withdrawn. Upon the recommendation of the Highways Committee the Council have decided to make application to Parliament in the next session for powers to enable the Council to construct tramways from the present terminus in Westminster Bridge-road across Westminster Bridge and along the Victoria-embankment, and the portion of the subway authorised by the Council's Act of 1902, from the Victoria-embankment to the north side of the Strand, with a connection between the proposed tramways and the tramways in Lambeth Palace-road. The reconstruction for electric traction of several further routes has now been completed, comprising those from the Elephant and Castle to St. George's Church and Old Kent-road several in and around Southwark, and one from Grange-road to New Kent-road. Some additional sections authorised by the Council's Act of 1901 have also been constructed, and have been certified as satisfactory by the Board of Trade. The report presented to the Council on Tuesday comments upon the disparity between the amount (£91,363) awarded by the arbitrator to the London, Deptford, and Greenwich Tramways Company, and the value of the undertaking as estimated by the Council's witnesses. The Council put the figure at £53,329. A vote of £95,000 has been made to cover the cost of acquisition. The company desire that the Council shall take over the service at as early a date as possible, and the Highways Committee recommend that they be authorised to make all necessary arrangements for this purpose. The Camberwell Borough Council have agreed to petition the House of Lords not to make any alterations in regard to tramways Nos. 4 and 10 in the County Council's Bill now before a committee of the House, the London, Camberwell, and Dulwich Tramways Company having lodged an objection to same. The County Council having enquired whether the Camberwell Borough Council would contribute a third of the cost of certain street widenings in connection with the construction of the County Council's tramway from Lordship-lane to Stuart-road, a recommendation was submitted at Wednesday's meeting of the Borough Council that the suggestion should be acquiesced in. The Council has adopted the recommendation of the Highways Committee that the underground conduit system of electrical traction, approved by the Council on Nov. 10 and Dec. 1, 1903, and on Feb. 23, 1904, for adoption for the reconstruction of the first sections of the Council's (Northern) tramways, and for the construction of certain new lines in connection therewith, be modified so as to provide for the use of a conduit slot 1in. instead of ¾in. in width. Application is being made to the Board of Trade for approval. The receipts for the four weeks ended June 18 amount to £12,488, against £8,596 last year, and for the period April 1 to June 18 the total is £130,202, against £108,071.

LIGHTING AND GENERAL.

Ellon.—The cost of installation of the electric light into the burgh is estimated at £2,950.

Hanley.—Sanction has been received to the borrowing of £5,800 for the purposes of electric lighting.

Portsmouth Telephones.—The subscribers connected to the Corporation exchange on June 16 totalled 1,761.

Wrexham.—Sanction has been received to the borrowing of £5,600 for extension of electric lighting cables and plant.

Annfield Plain.—The Urban District Council are corresponding with the Northern Counties Electricity Supply Company, Limited.

Holyhead.—Application is to be made for sanction to borrow an additional £1,000 for the extension of mains and sources of electric light.

Beckenham.—The consideration of the proposals for the extension of the electric lighting undertaking has been adjourned for three months.

Maskelyne Wireless Telegraph.—The De Forest Wireless Syndicate has acquired all the Maskelyne patents in respect to wireless telegraphy.

Tewkesbury.—The Chepstow and Rose Electricity Company intend to apply for a provisional order for the district, including the borough.

Erith.—Application is to be made for sanction to the borrowing by the Council of the further sum of £2,500 for extensions to the electricity supply works.

Poplar.—Cotton-street and return to Bow-lane is to be lighted by five arc lamps, and the necessary mains and also distributors are to be laid, at an estimated cost of £388.

Eastern Extension Australasia and China Telegraph Co.—The directors have declared an interim dividend for the quarter ended March 31 of 2s. 6d. per share, tax free, payable on the 15th inst.

Epsom.—The Urban District Council have agreed not to reduce the price of current to private consumers until that consumption, which stood at present at 5,548 8-c.p., reached an equivalent of 7,000 8-c.p.

Hackney.—From Jan. 1 next the charges for current will be as follows: for an hour's use per day, 7d. per unit for lighting and 3d. for power; for three hours, 3d. and 2d.; and for six hours, 2d. and 1½d.

Caerphilly.—The Barry Railway Company have deposited in the Private Bill Office of the House of Commons a requisition for leave to withdraw their opposition to the Caerphilly electric lighting provisional order.

Ware.—The Urban District Council's draft agreement with the North Metropolitan Electricity Company for the taking over and working of the Council's electric lighting order has been approved by the company.

Sale of Plant.—The Council of Exeter have for disposal various plant. Particulars of this sale and of another, concerning an electric dynamo, switchboard, etc., at the Glanne Wells, Builth, will be found in another column.

City and Guilds of London Institute.—Particulars of session 1904-5 of the courses of instruction at the institute's central technical college (Exhibition-road) and at technical college (Finsbury) will be found in another column.

City of London Electric Lighting Co.—The following dividends have been declared on account of the distribution for the year 1904:

Digitized by Google

on the preference shares 6s. per share, and on the company's ordinary shares 5s. per share, less tax.

Southend.—Cables are to be laid in Station-road and Chalkwell-avenue. During the month 19 consumers, with the equivalent of 1,068 lamps, have been connected to the mains, bringing the total number of lamps connected up to 37,201.

Refuse Removal.—Matthews and Yates, Limited, ventilating heating electrical engineers, of Cyclone Works, Swinton, are manufacturing a cyclone collecting plant for the car building sheds of the Brush Electrical Engineering Company, Limited, Loughborough.

Keighley.—The electricity sold during May amounted to 11,315 units, an increase of 2,219 units upon May, 1903, and there was also an increase of 42,757 units, or 32·7 per cent., in electricity sold from July 1, 1903, to May 31, 1904, upon the corresponding period 1902 3.

Swansea Telephones.—The Municipal Telephones Committee were on Monday considering the advice to apply for a mandamus to compel the National Telephone Company to grant intercommunication. After various points had been discussed the meeting decided to adjourn for a week.

Gillingham.—The last report of the engineer showed that 227 8-c.p. lamps, with three connections, had been connected to the mains since the last meeting of the committee, making a total of 10,730 8-c.p. lamps with 185 consumers connected. The laying of new mains is under consideration.

Stockwell.—At the recent festival of the Stockwell Orphanage Colonel Nisbet made an appeal for funds to provide an installation of electric light in the orphanage, which would, it was estimated, cost £1,400, but towards which £100 had been promised if the work were completed during the autumn.

Gloucester.—An agreement has been entered into between the Standing Joint Committee and the city authority in respect of lighting the shire hall with electricity. The city authorities will pay £100 towards the expenses. The Highways Committee have decided to appoint a consulting electrical engineer and obtain tenders for the work.

York.—The extensions at the electric lighting station are now almost completed, and it will be formally opened on the afternoon of July 18 It has become necessary to extend the mains throughout Coney-street and Spurriergate in consequence of the heavy demand for lighting and power purposes. The estimated cost of the work is £275.

London County Council.—On Tuesday tenders were received for the installation of electric light at the Poplar Technical Institute. It was agreed to lend the Fulham Borough Council £25,000 for electric light installation, and the Hampstead Borough Council £4,300 for electric light meters. Several notices of intention to lay mains were agreed to.

A.B.P. Accumulators. — The A.B.P. Accumulator Company report that they have just completed the erection of a battery, consisting of 256 cells, at the Leek electricity generating station, also 250 cells of their 23-plate type at the Corporation power station, Northampton. They have also delivered a complete battery of 58 27-plate cells to Constantinople.

Gravesend —The Town Council are about to extend their mains to the Milton Ironworks at a cost of £180. Applications have been received from intending consumers in Rosherville parish, and it has been arranged for a deputation from the Northfleet Council to confer with the Electric Committee on the subject of the extension of the Gravesend electric lighting order.

Bo'ness.—The Scottish Secretary has reversed his former decision, and has now sanctioned the loan of £25,000 for the proposed electric lighting of the burgh. The contractors provide, erect, and fit up the installation for the lighting of the whole of the burgh, the Town Council paying 2½d. per unit for public lighting. The contractors are bound to pay 6 per cent. on the capital expenditure.

Chertsey.—The Board of Trade having written to the Urban District Council in reference to the Staines, Egham, and Chertsey electric lighting order, and enclosing correspondence between the department and the Thames Valley Electric Supply Company, Limited, it has been decided to intimate to the Board that the Council are willing to support them in revoking the order.

"Malite" Fire-Resisting Cable.—The makers, Messrs. Johnson and Phillips' Electric Cable Works, Old Charlton, inform us that their Patent No. 24,755, dated as far back as Nov. 11. 1902, gives them the right of finishing these cables with flat leather strip braided around the core. This arrangement makes an extremely safe and neat design for car-shed flexibles and connections to mining plant.

Sunderland.—The Corporation Electricity Committee, which was muleted in costs owing to a misunderstanding, which involved their non-appearance before a Parliamentary Select Committee in connection with a petition against the Rural District Lighting Bill, have decided to protest against the order of the Select Committee as to costs. They contend that the committee had no power to order them to pay costs.

Aberdare.—The District Council recently decided to consider the destructor, electric lighting, and electric tramway as one scheme, and the surveyor was instructed to report thereon. At the June meeting it was resolved to allow the electric lighting scheme to stand over, and to obtain the report of expert engineers on the tramway and refuse destructor, and Messrs. Medhurst and Lloyd will be asked to report thereon.

Carnarvon.—The Council are about to purchase a site in Balaclava-road for the erection of electric light works at £1 000. The agreement with the National Construction Company is to be altered so that the maximum price to be charged should be 5d. per unit instead of 6d., and that the period for which the works should be maintained by the construction company be extended from 20 to 25 years. Mr. Price White, electrical engineer, Bangor, has been appointed engineer to supervise the work.

Holiday Sailings.—Messrs. J. and D. Robinson, Limited, 48, Wellington-street, Leeds, have again, in conjunction with Mr. Effingham Wilson, 11, Royal-exchange, E.C., issued "Robinson's Handbook," for holiday makers in all parts of the United Kingdom It is a most complete record and gives all the information required by the intending tourist from port to port in England, or thence to foreign ports, with the railway connections, etc.

Clyde Valley Electric Power.—The Clyde Valley Electrical Power Company's provisional orders in respect of the burgh of Milngarvie and portions of the parishes of Old and New Kilpatrick, in the county of Dumbarton, and in respect to portions of the parishes of Glasgow and Old Monkland, in the county of Lanark, have been granted. The Board of Trade have decided to dispense with the consent of the respective county councils.

Islington.—The electrical engineer has found that a certain amount of wear is taking place on the low-pressure pistons of the three 1,000-h.p. engines, and as this tends to reduce the efficiency of the engines by allowing steam leakage, his suggestion that tail rods be placed on the ends of the cylinders for the purpose of supporting the heavy pistons, and thereby preventing the wear, has been adopted. The estimated cost of the work is £100 per engine.

Swansea.—A notice has been issued by the electricity department of the Corporation in connection with the forthcoming Royal visit, informing persons who apply for a supply of electrical energy for illumination purposes on July 19, 20, and 21, 1904, that from 6 p.m. on July 19, 1904, the demand indicators installed will be "short-circuited," and that current will be supplied at a flat rate of 2d. per Board of Trade unit as measured by the meter fixed by the Corporation.

Stock Exchange.—The Stock Exchange Committee have ordered British Westinghouse Electric and Manufacturing Company's further issue of £116,353 4 per cent. mortgage debenture stock (redeemable) to be quoted in the official list. Application has been made to the committee to appoint a special settling day in Rhodes Electrical Manufacturing Company's 6,135 ordinary shares of £1 each, fully paid, Nos. 35,001 to 41,000 and 43,101 to 43,235; and 33,000 vendors' ordinary shares of £1 each, fully paid, Nos. 5,001 to 35,000, 41,001 to 43,100, and 43,236 to 44,135.

Swindon.—At the last Council meeting a report was read from the electrical engineer with regard to the extensions which would be required to the generating station in order to meet the demands for current for lighting and power purposes (other than tramways) for the autumn of 1905. Mr. Griffin was instructed to prepare plans and estimates of the cost (and so far as relates to the buildings in conjunction with the borough surveyor) of the required extensions, so as to provide for the estimated increased demand for the autumn of 1905, and also for laying the additional cables mentioned.

Long-Distance Telephone.—Telephonic communication will be opened between Manchester, Liverpool, Leeds, Hull, Wakefield, etc., and the chief exchange at Brussels to-day. The charge will be 8s. for a period of three minutes. Not more than two consecutive periods will be allowed to the same subscriber if other applications are on hand. The service, it should be understood, will be available only from call offices of the Post Office, and by the renters of telephone lines provided by the Postmaster-General. Double periods will be allowed at night on reduced terms to regular subscribers.

Removals.—Mr. A. R. Bennett, M.I.E.E., has removed from 66, Renfield street, Glasgow, to Queen Anne's-chambers, Broadway, S.W., where he will continue his practice as a consulting telephone and general electrical engineer. Mr. Walter P. Adams, M.I.E.E., of 35, Queen Victoria-street, E.C., has removed to new offices at 28, Victoria-street, Westminster, S.W. Saxby and Farmer, Limited, have removed their head office from Kilburn to 53, Victoria-street, S.W. Messrs. S. Parsons and Co. have removed to larger premises at Horton Ironworks, Beckside-road, Bradford. They have also opened a town showroom at 7, Aldermanbury.

Inquest.—Mr. R. A. H. Tovey, the Doncaster borough coroner, held an enquiry on Saturday into the death of John William Hankinson, of 8, West-street, electric lamp cleaner and motor attendant in the boiler shop at the Great Northern Plant Works, which took place in the infirmary on Friday. Mr. Phillips, assistant manager at the works, represented the railway company, and Mr. Jos. Roddis (from the offices of Mr. Gichard, of Rotherham) represented the widow. Mr. Joshua Dodgson, factory inspector, was present, and occupied a seat by the side of the coroner. After hearing the evidence, the coroner said that there was not the slightest evidence to show that the deceased was actually cleaning the machinery when the accident happened. It was one of those unfortunate accidents which would happen. One of the jurymen had suggested that the belt and pulley might have been protected. They had heard the questions put by the Government inspector, and they might take it for granted that there had been no neglect, or the inspector would have seen to it. He thought they might assume that everything had been done which the law required for the protection of this machinery. It was a case which seemed to resolve itself in effect to some thoughtlessness or forgetfulness on the part of the deceased. They could not but come to the conclusion that it was a pure accident. The jury retired and were absent nearly half an hour. Their verdict was "Accidental death, caused by the pulley and belt not being properly protected." Mr. Phillips said he would like, on behalf of himself and the officials, to express their sympathy with the widow and children in their sad bereavement. It was a very regrettable affair and particularly painful. The Coroner: I am sure the jury will concur in that, as I do. These things will happen, and there does not appear to have been anybody to blame. The jury have added a rider. It is their rider, not mine,

Digitized by Google

Sunday Telephones.—At the last meeting of the Newport Chamber of Commerce the president alluded to the want of facilities for the public for using telephone call offices on Sundays. The matter had come under his personal consideration at Bristol a little while ago, when he found that the main office of the National Telephone Company was closed. He stated that since he had complained of that the main office had been opened on Sundays, and he understood that the telephone company were ready to open an office at Newport on Sundays if the site for such office could be settled.

Retford.—A committee has been appointed with power to employ an expert in order to present an electric lighting scheme to the Town Council. It is estimated that to begin with they would have to provide for about 2,000 lights. Public lighting is not proposed at present. A consumption of about 105,000 units for the first year is anticipated, which, at 4d. per unit, would be an income of over £1 700. A system to cover about five miles is estimated to cost £3 000. This would require two or three gas-engines of 150-h.p. in a building which would cost not more than £800. Altogether it is thought that the whole could be carried out for an outlay of £8,000.

Persian Telegraphs.—The telegraph line is completed as far as Kerman. Finally, it will connect direct with India, and besides relieving the heavy pressure on the cable, will, it is thought, prove cheaper to maintain. It will also produce various incidental improvements along its course. Progress in the first part was at the rate of 15 miles per week, but the line is now proceeding at 20 miles per week, and no fanaticism or hostility has been aroused. The line is expected to be complete by the end of this summer. It costs £130 per mile. The wire has been supplied by Messrs. Docman, Long, and Co., of Middlesbrough, and the posts by Messrs. Siemens Bros.

Pontypool.—The Urban District Council recently asked the Pontypool Electric Light Company for permission to fix a gas bracket on a company's standard. This the company declined, but made an offer, which has been accepted, to the effect that if the Council would bear the cost of fixing a lamp, bracket, and fittings, to be supplied by the company, and find the renewals that would become necessary from time to time, the company would find the necessary energy to supply a lamp of 30 c.p., to be switched on from the time the other arcs are switched off to sunrise, for a nominal consideration of 15s. per annum; or they would give a small arc of about 200 c.p. on the same terms for £3 per annum.

Derby.—The National Telephone Company are now transferring the wires from overhead to underground. The town has been divided into over 40 areas, in each of which is to be fixed a distributing point. From the exchange to these distributing points the wires will be placed underground. At each distributing point a special post will be fixed, to which, by means of overhead wires, the subscribers of that particular area will be connected. As the areas are not large, only one span of wire will be necessary between each building supplied and the distributing point. This will very considerably reduce the number and length of overhead wires, and as these remaining will be very short, there will be little possibility of breakage.

St. Marylebone.—The Borough Council have adopted a report of the Electric Supply Committee recommending the Council to empower them to enter into an agreement with the Metropolitan Company to supply electricity until March 31, 1905, and to entirely cease not later than March 31, 1906. The company were to take the revenue and pay to the Council a sum in respect of the interest on the amount and the capital sums payable by the Council to the company under the award, such interest to range from 4 to 3 per cent. The Council were to have complete control over capital expenditure, and the charges were to remain the same. Councillor Debenham remarked as soon as they completed the purchase it would be necessary to put in fresh engines and take over the other responsibilities.

Bury.—The charges for current have been fixed as follows: Lighting—places of worship, offices, banks, workshops, warehouses, public halls, and other short hours unclassified consumers, 5d. per unit flat rate instead of 6d., and 3d. per unit on the maximum demand system; shops, 4½d. per unit; hotels, public-houses, private houses, and other unclassified consumers, 6d. per unit. Any consumer included under these classes whose average account on the maximum demand system this year is lower than it would be under the proposed flat rate, is to have the option of continuing under the maximum demand system. For motor power—the initial price of 3d. per unit is to be reduced to 2½d. for the use of the maximum demand for an average of one hour per day or 1,000 units per quarter, and all additional units to be 1d. per unit as at present.

Hammersmith.—The last report of the Electricity and Lighting Committee shows that the premises of 12 additional consumers, representing a maximum of 388 8-c.p. lamps, have been connected to the mains, that seven consumers have been disconnected, and that the present number of consumers taking current from the mains is 1,482. It has been decided to lay a new main in continuation of that in Great Church-lane, at an estimated cost of £127. We deal elsewhere with the tenders for supplying the additional plant required in connection with the extension of the electric lighting installation. The tenders include the supply of two 1,500-kw. generating sets. The Guardians have appointed Mr. J. S. Enright, 68, Lincoln's-inn-fields, W.C., as electrical engineer to prepare specifications in connection with, and to superintend the carrying out of, the electric installations at the workhouse and infirmary buildings now in course of erection at Wormwood Scrubs, Shepherd's Bush, W.

Strike of Telephone Operators.—The strike of telephone operators engaged at the Holborn Exchange of the National Telephone Company was brought to a satisfactory conclusion on Monday, after a conference between three representatives of the girls and the manager, Mr. E. L. Gaine, and several of the officials of the company, at Telephone House, Victoria-embankment. The operators laid before Mr. Gaine their grievances, especially with regard to the extra hours of work they had recently been called upon to undertake through the introduction of a new schedule of duty. Mr. Gaine pointed out that no duty had been imposed upon them in excess of their contract with the company, but he thought that some of the hours of duty were unduly long and should be modified, and gave instructions for new time-tables of duty to be prepared accordingly. In consequence the operators will now be engaged for 8½ hours per day from Monday to Friday, and on Saturday about six hours, whereas under the schedule to which the operators objected the hours were nine, and in some cases ten, each day. One hour will be allowed for dinner and tea inclusive.

Grimsby.—The electrical engineer's last report contains the following: "With reference to the flame arc lamps recently tested, I have to report that they proved satisfactory. Comparing them with the ordinary 10-ampere street arc lamps, the chief points I noticed were: (1) That they gave from two to three times as much light. (2) That the annual cost of running, including the cost of current and carbons, but excluding trimming, repairs, and interest on capital, would be about £20. 19s. 6d. per lamp for 3,600 hours, as compared with £14. 15s. 4d. The cost of the special carbons required is five times as much as the cost of ordinary carbons. (3) The lamps are not quite steady, they feed irregularly, and this causes a flickering in the light. (4) The cost of the lamps only without any accessories is about £8. 10s. each, as compared with £4. 10s. (5) If a smaller lamp were used, the annual cost of running might be reduced to about £14, and the light would, I think, be greater than it is at present. To alter the existing lighting would be a serious expense, as all the existing lamps would have to be scrapped, and some of the accessories would have to be altered. The capital cost of the alteration would be from £10 to £12 per lamp. I would suggest, however, that when any extension to the public lighting is proposed this matter be further considered."

Curtis Turbines Supplanting other Apparatus in St. Louis, U.S.A.—The Union Electric Light and Power Company of St. Louis, which is a consolidation of the Missouri-Edison Electric Company, the Imperial Electric Light, and the Citizens' Electric Light and Power Company are building a large power station on the Mississippi River in North St. Louis. This power station when completed will supply all of their demands, shutting down three existing power-houses with miscellaneous types of apparatus. This power station will have installed therein four 5,000-kw., and two 2,000-kw., 25-cycle, 6,600-volt alternators, direct connected to Curtis turbines. In several sub-stations throughout the city motor-generators will be used for distributing direct current on 110 and 220 volt systems. The power-station is being designed with a view of securing the highest possible economy of operation. Being located on the river front and also having railway switching facilities, coal may be received by barges and by rail. The two 2,000-kw. turbines will be operated with Wheeler condensers, the four 5,000-k.w. turbines with Worthington condensers. The Union Company is to furnish the St. Louis Transit Company with 9,000 kw. continuously, and the St. Louis Transit Company is now installing two sub-stations. Sub-station No. 1 will have seven 1,000-kw. converters, sub station No. 2 will have two 1,000-kw. converters. The distribution mains to the Transit Company's power stations will be underground.

Shipley.—The rapid progress of the District Council's electricity department has made it necessary to almost double the station. In the year ended March 31, 1903, 470,530 units were generated, of which 169,294 units were required for traction and 90,780 units for private lighting and power purposes, the remainder being used for public lighting, the lighting of the works, and for motive power required at the sewage works. In the year ended March 31 last 926,244 units of current were generated, of which 362,411 units were for traction and 190,115 for private lighting and power purposes. The output has thus nearly been doubled within one year, and the total income has grown in the same proportion—*i.e.*, from £2,725 to £5,210. The loss in 1903 of £446 has fallen to £125. To meet the growing demand contracts have been let for an additional 300-h.p. turbine and dynamo, and the switchboard is to be extended to provide for three additional generators. Another boiler, superheater, and mechanical stoker, and other necessary apparatus are also about to be added, which will increase the producing power of the station by 60 per cent. The extensions at Dockfield have just been opened, and comprise a building covering 418 square yards. There are new offices, battery, storage, and testing rooms. The building has been erected from the plans of Mr. Sam Bradley by Messrs. Hartley and Kemplay (masons), and Mr. Joshua Hobson (joiner), the other contractors being Mr. Samuel Rushworth (plumber), Mr. W. Holmes (plasterer), Mr. T. Thornton (slater), and Mr. H. Hirst (painter).

London Gazette.—The first meeting in the estate of Henry Binks, electrical engineer, carrying on business at 34, Leaderhall-street, London, and residing at 4, Highbury-crescent, Highbury, Middlesex, will be held at 11 a.m. on July 7 at Bankruptcy-buildings, Carey-street, London, W.C. The public examination in the estate of Carl Vigant Tyge de Falbe (lately carrying on business as the Electrical and General Contracting Company), now residing at 1, Penywern-road, Earl's Court, and lately trading at 17, Shaftesbury-avenue, London, will be resumed at 11.30 a.m. on July 20 at Bankruptcy-buildings, Carey-street, W.C. A first and final dividend of 2s. 6½d. in the £ has been declared in the estate of Gilbert Jackson and David Smith (trading as Jackson and Smith), electrical engineers, 6, Annes-well-street, Carlisle, now payable at the Official Receiver's Office, 34, Fisher-street, Carlisle. The partnership between Henry Turner and Charles Richard Douglas Bearcroft, electrical engineers, 15, New Broad-street, London, E.C. (trading as H. Turner and Co.), has been dissolved by mutual consent. The Reliance Electric Company, Limited, will be wound up on account of liabilities. Mr. E. W. Bundy, 35, Philips Park-road, Bradford, Manchester, has been appointed liquidator. The final meeting of the Blake-Morscher Electrical Ore Separator Syndicate, Limited, will be held at 20, Copthall-

Digitized by Google

avenue, London, on July 26 at 3 p.m. Royal assent has been given to the Electric Lighting Orders Confirmation (No. 1) Act, 1904; Govan Electric Lighting (Further Powers) Act, 1904; Chesterfield Corporation Tramways and Improvements Act, 1904; St. Marylebone Electric Lighting Act, 1904.

Newcastle.—With regard to the opening of the electric light station, mentioned in our last issue, we cull from the *Staffs Advertiser* as follows: "The new works have been erected on land adjoining the gasworks. The buildings have been put up by Mr. S. Wilton, jun., of Newcastle, and they comprise an engine-room 50ft. square—a lofty apartment, the walls of which are entirely lined with glazed bricks—and a battery room 50ft. by 12ft. The machinery comprises two 60-h.p. gas-engines, made by Messrs. Andrew and Co., Limited, Stockport, rope driven, with two 30-kw. dynamos by the Electric Construction Company, Bushbury, Wolverhampton, and a switchboard by Messrs. Crompton and Co., London, arranged for a three-wire continuous current supplying 230 volts pressure to consumers. The board is arranged for running the machines on the town, together with a storage battery for the same when required. Automatic circuit breakers are provided. The battery, constructed by the Electric Power Storage Company, London, comprises 130 cells, arranged for a 230-volt supply, and has a capacity for supplying about 200 8-c.p. lights for eight or nine hours. The battery is provided with a switch on the board by which the supply is regulated. The cables were supplied by Callender's Cable Company, London. A feeder, consisting of three cables, carries the total current required to a feeder pillar in the centre of the town, from which distributing cables are taken through distributing pillars over the compulsory area. These pillars are so arranged that any section of the town can be cut off independently. In the engine-room are a five-ton crane over the engine beds, and a two-ton crane over the dynamo beds. When the supply was first turned on a month or two ago about 430 8 c.p. lamps were connected up, and it was considered a very good start, but so rapid has been the extension that the total capacity of the works is already almost exhausted, and nearly 2,000 8-c.p. lamps are now connected. It is intended to supply current for power as well as lighting purposes, if required. The price charged for the light at present is 6d. per unit. The electrical engineer in charge of the works is Mr. J. F. Shoolbred, formerly of the Stockport electric light station.

Coventry.—The Electric Light Committee's annual report states that the capital expended during the year has been £16,758, bringing the total expenditure to date up to £119,470. The amount raised on loan is £93,474, and £12,000 has been received on temporary loan, while the receipts on various accounts have amounted to £1,543. The balance of £26,011 has not yet been raised. The total capital sanctioned is £110,485. The amount of capital repaid is £788, and the sinking fund amounts to £9,231. During the year the number of consumers has increased from 449 to 536, and the equivalent of lamps connected from 39,605 (8 c.p.) to 53,746. Further connections are being made. The number of units sold has increased from 566,731 to 920,192, and the revenue from sale of current and meter rental from £8,076 to £10,844. The increase in units sold to private consumers has been from 504,218 to 857,242, and the revenue from this source is £9,581, against £7,057. The working expenses are £4,598, as against £3,691 in the previous year. The profit on working is therefore £6,245. 11s. 9½d., against £4 385. 2s. 10½d. last year. The capital charges amount to £5,470. 0s. 3d. The net profit therefore is £775. 11s. 6½d., as against a loss of £189. 2s. 3½d. last year and £1,807. 19s. 7½d. the year before. The committee recommend that the balance of profit, £775. 11s. 6½d., be carried forward to next year's account. The sale of current shows a profit of ¼d. per unit, against a loss in every previous year, varying from 8d. per unit in the first year to ·08d. in 1903. Coal cost last year £1,461, which was an increase of £376 on the previous year, when the cost was £1,085. The manager in his report states: "During the year we have connected 87 consumers, which are represented by 4,871 lamps and 309 h.p. of motors. We have laid 6¼ miles of mains, besides 4¼ miles of spare pipes." The total number of lamps connected at the end of the year, including motors, was 53,746, and the number of lamps which were connected at the end of 1903 was 39,605, showing a total increased communication of 14,141. The cost of manufacturing current amounted to only 41 per cent. of the revenue, against 45·7 last year. The station costs having been reduced to the very low price of 1·15d. per unit, Mr. Jeckell in his report said: "With regard to the cost of manufacture at the works, though it was very low for the last year, it has been reduced still further—viz., it has been reduced from 1·513d. per unit to 1·159d. per unit."

PROVISIONAL PATENTS, 1904.

JUNE 20.

13902. Improvements in terminating insulators. William Aitken, care of British Insulated and Helsby Cables, Limited, Milton-road, Edge-lane, Liverpool.

13903. Improvements in means for producing electric arcs from alternating currents also applicable for rectifying alternating currents. Ezechiel Weintraub, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, June 20, 1903, being date of application in United States.) (Complete specification.)

13925. Improvements in electric arc lamps. George Willis Matthew, 22, Southampton-buildings, Chancery-lane, London.

13927. An improved system and apparatus for electrically operating bulkhead doors, hatches, or the like. Allen Parry Jones, 55, Chancery-lane, London. (Long Arm System Company, United States.)

13928. Improvements in automatic electric cut-out mechanism. Allen Parry Jones, 55, Chancery-lane, London. (The Long Arm System Company, United States.)

13933. Improvements in or relating to storage battery separators. Alfred Julius Boult, 111, Hatton-garden, London. (Norman Dodge, United States.) (Complete specification.)

13937. Improved system of installation of electric apparatus for traction in mines or other places containing explosive gas. Edgard François Joseph Modesse, 111, Hatton-garden, London. (Complete specification.)

13945. Improvements in power transmitting devices. Franklin Wise Howorth, 46, Lincoln's-inn-fields, London. (Electric and Train Lighting Syndicate, Limited, Canada.)

13947. Improved construction of electric tumbler switch. George Smith, 173, Fleet-street, London.

13952. Apparatus operating with automatic regulation for submitting gases and vapours to the action of the electric arc. Oliver Imray, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Société Anonyme d'Etudes Electro-Chimiques, Switzerland.)

13979. Improvements in electric lamps. Edgar Alfred Carolan, 83, Cannon-street, London. (General Electric Company, United States.)

13984. An improvement in electric fuseboards and fuses. George Mark Pinkerton, 10, Camomile-street, Bishopsgate-street Within, London.

JUNE 21.

14020. Improvements in electrostatic apparatus for measuring electrical potential differences. Edgar Walford Marchant and Gladstone Walter Worrall, The University of Liverpool. (Complete specification.)

14032. Improvements in miners' and other portable electric lamps. William Edwin Gray, 53, Bayham-place, London.

14058. Improvements in solutions for the electro-deposition of metal. Louis Potthoff, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

14059. Improvements in apparatus for electro-galvanising. Louis Potthoff, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

14066. Improvements in conductor and collector devices for electric railways and tramways. André Bolzano, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

14066. An improved high-voltage battery. Lionel de Gournay, 40, Chancery-lane, London. (Complete specification.)

14071. Improvements in raising and lowering of arc lamps. Herbert Henry Berry and Ernest Skinner, 78, Upper Thames-street, London.

14072. Improvements in the transmission of vibrating or wave-sounds, messages, signals, and the like. Robert James White, 28, St. John's-park, Holloway, London.

JUNE 22.

14097. Improved box and lid for electric accumulators on board ships, motorcars, and the like. Arthur Albert Smethurst and Thomas Henry Bishop, 44, Lodge-road, Southampton.

14105. Improvements in and relating to electric cells. Ernst Wichmann, 112, Potsdamerstrasse, Berlin, Germany. (Complete specification.)

14111. A self-locking contact maker. Joseph Henry Golding, Amhurst Electrical Works, Garnham-street, Stoke Newington, London.

14117. Improved form of protected conductor rail for electric railways. Richard Owen Sullivan, 170, Portland-road, Jesmond, Newcastle-upon-Tyne.

14128. Improved method of preliminary treatment for accumulator plates. Henry Leitner, Lynton, Dartnell Park, Byfleet, Surrey.

14135. Improvements in or relating to apparatus for supplying current to electrically-propelled vehicles and the like. Torius Larssen Kolkin, The Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London.

14136. Improvements in brush-holders for electrical machines. William Horace Foot, The Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, June 24, 1903, being date of application in United States.) (Complete specification.)

14139. Improvements in and connected with arc lamps. Francois de Zea Bermudez, 33, Cannon-street, London.

14145. Improvements in or connected with telephonic instruments. Charles William Fisher, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

14147. Improvements in and relating to the electrolytic deposition of metals. Sherard Osborn Cowper-Coles and The Metals Corporation, Limited, 70, Chancery-lane, London.

14148. Improvements in vapour electric lamps. Osias Otto Kruh, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, June 22, 1903, being date of application in United States.) (Complete specification.)

Digitized by Google

14166. Improvements in or relating to electric clocks and electromotive apparatus thereof, and for other purposes. Sebastian Palmer, Palace-chambers, Westminster, London. (Complete specification.)

14163. Improvements in movable overhead frogs or switches and section insulators for electric railways and tramways. Charles Hesterton Merz and Sydney George Redman, Norfolk House, Norfolk-street, Strand, London.

JUNE 23.

14170. Improvements in electrical accumulators. Thomas Rigg, 5, Corporation-street, Birmingham.

14176. Improvements connected with electrical collector rails. Thomas Francis Jones, 9, Tempest Hey, Liverpool.

14195. Improvements in electric conductors for tramways worked on the conduit system. Wilfrid John Aris Watkins, 106, Chichele-road, Cricklewood, London.

14196. Improvements in electrodes for arc lighting. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

14221. Improvements in and relating to galvanic batteries. Reinhold Dréibholz, 6, Lord-street, Liverpool. (Complete specification.)

14231. Improvements in electric sparking plugs for internal-combustion motors. Hippolyte Joseph Le Force, 70, Chancery-lane, London. (Date applied for under Patents Act, 1901, June 24, 1903, being date of application in France.) (Complete specification.)

14239. Improvements in or relating to electric traction engines. Coloman de Kandó, 111, Hatton-garden, London. (Complete specification.)

14250. Improvements in dynamo-electric machines and the like. Ludwig Torda, 40, Chancery-lane, London.

JUNE 25.

14281. Improvements in the method of and means employed for supporting and connecting the trolley wires of overhead electric systems and in the method of insulating such connections. James Haydock and Thomas Smith Jones, Penny Bank-chambers, Halifax.

14294. An improvement connected with the "live rails" of electric railways. Thomas Massey Lynch, 15, Water-street, Liverpool.

14300. Improved arrangement of plant for generating stations. Bernard Mervyn Drake and Drake and Gorham, Limited, 66, Victoria-street, Westminster.

14326. Improvements in and relating to the generation of electricity. William Strickland, 70, Chancery-lane, London.

14250. Electrically-operated signalling and braking devices for railway trains. Peter Krause, 65, Chancery-lane, London. (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published July 14, 1904.

1903.

11760. Electrical switch apparatus. Jones.

13741. Dynamo-electric machinery. Midgley and Wright.

13746. Method for operating signals on electric railways. Young.

13822. Dynamo brushes. Siebers.

14173. Breaking and controlling electric circuits. Le Tall. (Cooper Hewitt Electric Company.)

16534. Secondary galvanic batteries. Schneider and Beissbarth.

18253. Magnetic controlling devices. Carolan. (General Electric Company.)

18343. Electric vapour lamps. Carolan. (General Electric Company.)

18344. Electric lamps. Carolan. (General Electric Company.)

19366. Process relating to the reducing of metallic compounds and the fusing of metals, in particular of nickel and iron in the electric furnace. Abel. (Siemens und Halske Aktiengesellschaft,)

26850. Selective signalling systems. Fairweather. (Stromber Carlson Telephone Manufacturing Company.)

26851. Central telephone exchange apparatus and connection. Fairweather. (Stromberg Carlson Telephone Manufacturing Company.)

1904.

2008. Electric induction motor meters. Compagnie pour la Fabrication des Compteurs et Matériel d'Usines à Gaz. (Date applied for under International Convention, Feb. 26, 1903.)

3221. Electric telegraph apparatus. Brown and Hardie.

3692. Electric bells or gongs. Heyes and Heyes.

4567. Electric controllers. Eastwood.

7224. Cluster sockets for electric lamps. Fairweather. (Benjamin Electric Manufacturing Company.)

9647. Electromagnetic machines for igniting in explosion motors. Pichard and Meunier.

9375. Electrical resistances. Vedovell (nee Del Castello). (Date applied for under International Convention, Oct. 19, 1903.)

9950. Collector rings of alternating-current generators and motors. Kandó.

10171. Electric converters. Müller.

10623. Automatic trolley controlling devices for electric tramcars and the like. Nichols.

10986. Printing telegraphs. Sheehy.

11525. Magnetic compasses. Lilley.

11568. Electric current switches. Hall and Hackblock.

NOTES.

Radium.—Prof. Geitel, of Wolfenbuttel, has just been successful, it it reported, in discovering comparatively large quantities of radium in the thermal mud used during the last few years at Baden-Baden for medicinal purposes.

Royal Institution.—A general monthly meeting of the members of the Royal Institution was held on Monday afternoon, the Duke of Northumberland, K.G., president, in the chair. Viscountess Gort, Mr. M. H. Speilmann, and Mr. W. R. W. Sullivan were elected members.

Wireless Telegraphy.—It is reported that the Marconi system of wireless telegraphy is being introduced on board the Northern Lights Commissioners' steamer "May." The system is also being installed at the light-house on Inchkeith, chiefly as an experiment with a view to the introduction of it to other steamers and lighthouses under the control of the Commissioners.

The New Telegraphic Code.—The new code decided upon by the International Telegraph Convention last summer came into operation last Friday. Its advantage to concerns trading abroad is shown by the fact that the cost of cabling in cipher is reduced by something like one-half. Any pronounceable combination of 10 letters may now be employed, subject to the proviso that combinations formed by the union of two or more actual words are inadmissible. It is calculated that the enormous total of 20,000 million combinations can be used.

N-Rays.—A suggestion is advanced by M. Jean Becquerel that there are two elements in the N-rays, consisting of an undulatory movement propagating itself with the speed of light, and another mode of energy propagating itself more slowly. It will be remembered that M. Becquerel demonstrated that metals transparent to N-rays become opaque to them when their surface is subjected to the influence of chloroform or ether. M. Becquerel considers that it is the latter of the elements now attributed by him to the N-rays which is arrested by metals under the action of an anæsthetic.

Electrical Ore Finding.—The Daft and Williams electrical prospecting system, of the results accomplished by which we recently gave some particulars, is to be employed on some mines in the Coniston district, near Barrow-in-Furness. The experiments, which will be carried out entirely at the expense of the Electrical Ore Finding Company, are intended to prove whether it is worth while spending further capital upon what has hitherto been an unremunerative undertaking. Upon metalliferous lodes being located by the electric waves, a bore or shaft will be sunk to verify the indications. The results are expected to be ascertained definitely within a few days.

Atmospheric Pressure.—Now that the working of the Meteorological Office is under consideration, it is interesting to note the opinions recently expressed by an official of the Norwegian Meteorological Institute. He considers that too little attention has been paid to the electrical conditions of the atmosphere, and that such investigations as have been carried on in this sphere are impaired by the observations being generally made in the lowest strata of the atmosphere. He also remarks that the distribution of atmospheric pressure and temperature is often quite different from what might have been expected from the telegraphic reports of the previous day, leaving the impression that there are unknown factors in co-operation.

Electric Arcs between Mercury and Carbon.—In No. 10 of the *Physikalische Zeitschrift* Dr. L. Cassuto describes some experiments on electric arcs in mercury and carbon. From measurements of the electric tension and current intensity made with both directions of the current and with different electrode distances, it is inferred that for equal current intensities and equal electrode distances the electrode tension of the arc will be higher if the mercury be the cathode and the carbon the anode than in the opposite case. The sum of the anode and cathode tension falls is practically identical for both senses of the current, whereas the tension fall in the arc column is higher in the case of the mercury being cathode than *vice versâ*. These phenomena are accounted for as follows: The column of the electric arc between the mercury and carbon will show nearly throughout its length, irrespective of the direction of the current, the bluish light characteristic of mercury vapour, mercury being vaporised much more strongly than solid carbon. Now the vaporisation of a mercury anode is greater than that of a mercury cathode, the potential fall being higher in the former case. A mercury anode will therefore supply the electric arc column with more vapour than a mercury cathode. The potential fall in the arc column, however, depends on the amount of vapour derived from the electrodes, increasing as the latter decreases. The potential fall in the electric arc column must, therefore, be smaller in the case of a mercury anode than in that of a mercury cathode with less vaporisation.

Aerial Electricity.—Some particulars are given by the *Scientific American* of the growing use of windmills in the Western States for generating electricity in connection with agriculture. The question of utilising the wind for driving farm machines is of great importance to farmers in those regions, as there are no large streams for them to harness, while wind is abundant. The wind has now been harnessed for generating electricity for use generally on the farm. The earlier mills were employed experimentally to generate electricity for lighting the barns and homes, but their success stimulated some to more ambitious efforts. To-day a good many of them are being run to generate sufficient power to operate small motors. Several windmills are worked together on some farms to operate the generators, and in this way 10-h.p. motors are working in the field continually. Several motors of 2 h.p. and 3 h.p. are operated in the field, and better results are obtained in this way than by one large single motor. By distributing the windmills and motors in different parts of the farms, more favourable results are obtained than by any other method. Another example of the use of the windmill for generating electricity is provided by the village of Askov, in Denmark. The windmill can be supplemented by a small petrol engine in case of a period of quiet weather. There is storage capacity for four or five days, so the engine is seldom required—only about 30 days every year. An ingenious contrivance enables the speed of the dynamo to be controlled and regulated. From this station the whole village is supplied with light, and power is provided for industrial and agricultural purposes. A farm in the neighbourhood, about 80 acres in extent, has a private plant of the same type, from which illumination and also power for driving all the machinery is obtained. The whole of this latter installation, including windmill, dynamo, etc., cost only £230.

Disruptive Discharges at Very High Tensions.—According to a communication recently made before the French Academy of Sciences, Mr. de Kowalski has performed some experiments with three continuous-current machines of the Thury system, built by the Compagnie de l'Industrie Electrique et Mécanique, of Geneva, and capable of yielding a current intensity of one ampere under a maximum tension as high as 20,000 volts. By connecting these three machines in series potential differences as high as 70,000 volts could readily be obtained at the

Digitized by Google

terminals of the machine. The results of de Kowalski's researches are as follows: (1) Continuous-current electric arcs at high tensions and small current intensities will, generally speaking, show the same behaviour as the alternating-current arc investigated by Messrs. Guye and Monasch. The author suggests a similar distinction between a stable and an unstable zone, while the critical zone observed by the above investigators with alternating arcs has not been found to exist in the present case. (2) In the stable zone, the ratio between the length of the arc, the potential fall, and the current intensity, appears to be expressed by a linear equation. (3) The limiting length of the stable arc depends on the current intensity and on the potential difference on the terminals of the machine, as may be inferred from the following figures:

V =	20,500	30,400	25,600	40,000	40,000	30,000
I =	0·023	0·024	0·031	0·032	0·08	0·04
δ =	1·45	3·48	1·82	5·15	7·60	4·70

In the above table V represents the potential difference at the terminals of the machine in volts; I the current intensity in amperes; δ the length of the stable arc in centimetres. (4) In the unstable zone the continuous-current arc shows an asymmetrical aspect, while being nearly fixed at the cathode it will tend successively and rather rapidly towards different points of the anode.

Calcium Carbide.—A patent has been granted in the United States to Mr. A. H. Cowles, of Cleveland, for a process intended for the continuous production of calcium carbide, which is maintained in a molten condition in order to remove it from the furnace. *Electrochemical Industry* of New York gives a description of the process. The charge is used as resistance conductor. The furnace used is illustrated in vertical central section in the accompanying

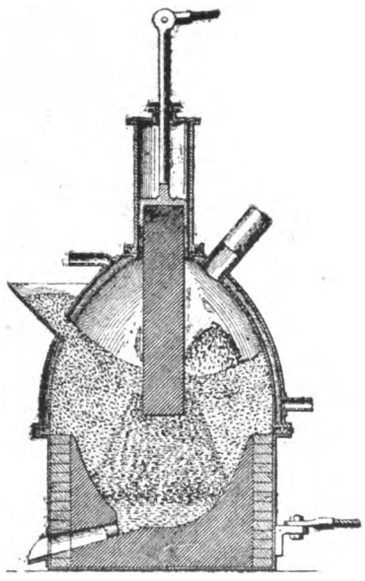

diagram. It has a solid carbon hearth surrounded by a layer of firebrick and a sheet-iron casing. A tapping-hole is provided, and a terminal, which connects the hearth with the source of electric current. An insulating ring of asbestos separates the hearth casing from a dome-shaped, water-jacketed, sheet-iron structure, with water inlet and outlet. A pipe for carrying off waste gases and charge openings are also provided. The other electrode is made of carbon and suspended vertically in the furnace. It is intended to produce superheated molten carbide, which means that the carbide has not only been produced and melted by the heat from the resistance conductor, but has also been raised to such a temperature that it will run through a tapping-hole without requiring an additional supply of heat.

Power Factor Regulation.—At a recent meeting of the American Institute of Electrical Engineers at Chicago Mr. B. G. Lamme was the contributor of a paper on "The Synchronous Motor for Regulation of Power Factor and Line Pressure." The conclusions of the paper, taken from an advance proof, are as follows: (1) A synchronous motor can be used to establish leading or lagging currents in its supply system by suitable field adjustment, and can thus affect or control power factor or phase relations of the current in the alternating-current system. (2) A synchronous motor will set up leading or lagging currents in its supply system if its field strength is held constant, and the pressure of the supply system is varied above or below that generated by the synchronous motor. Such leading or lagging currents in the supply system will tend to vary the pressure of the system. A synchronous motor can thus act as a regulator of the pressure of its supply system. (3) This regulating action is greatest with synchronous motors, which have the closest true inherent regulation (as indicated by high field magnetomotive force compared with the armature magnetomotive force) in distinction from machines which have close apparent regulation obtained by saturation of the magnetic circuit. (4) If the synchronous motor is used both for regulating the power factor for neutralising the effect of other apparatus on the circuit, and for regulating or steadying the pressure of the supply system, its normal capacity for regulating will be diminished. (5) The most suitable speeds for best electrical conditions will in general be considerably below highest possible speeds as limited by mechanical conditions. (6) Heavy dampers will increase the effectiveness of the regulating tendency. (7) If the synchronous motor can be used for power purposes as well as for regulation, its apparent capacity is increased. This is due to the fact that the regulation is obtained by means of a wattless component and the power from the energy component, and the algebraic sum of these two is greater than their resultant which fixes the current capacity of the machine. (8) Synchronous converters in general are not suited for regulating the pressure or controlling the power factor for an alternating-current system. (9) The cost of synchronous motors for regulating purposes will in general be lower than for alternating-current motors or generators of customary speeds, and will approach more nearly to turbo-generator practice.

The Disappearance of the Radioactivity Produced by Radium on Solid Bodies.—Messrs. P. Curie and J. Danne a short time ago investigated the law representing the disappearance of the radioactivity of a solid body which had been exposed to the radium emanation for a certain length of time. In a communication to the French Academy of Sciences they recorded graphically the results of their experiments by means of a set of curves where logarithms of the intensity of the radiation were plotted as ordinates and the time as abscissæ, being counted from the moment of the plate being withdrawn from the action of the emanation. It was shown that the intensity of radiation in terms of time is given by the difference of two exponential functions. These results, as pointed out in a recent note presented to the same academy, may be accounted for theoretically on the basis of Rutherford's views, supposing the emanation to act on the solid walls so as to give rise to the formation of a radioactive matter, B, disappearing spontaneously according to a simple exponential law with a coefficient, *b*. While disappearing this matter, B, would give rise to the formation of another radioactive substance, C, disappearing in turn according to another simple exponential law with the coefficient, *c*. Supposing both of these two substances to emit Becquerel rays, the above law could be readily accounted

Digitized by Google

for. In the special case of the substance C radiating alone a remarkable coincidence would be obtained between the formula and the experimental results. According to the above, is would seem as though the substance B were devoid of any radioactivity, being converted into a substance, C, which alone would emit Becquerel rays. Now, in the case of *b* being superior to *c*, the inactive substance B would disappear more rapidly than the substance C; some hours after the beginning of the disactivation, the substance C would exist alone at the surface of the body. In the case, however, of *b* being smaller than *c*, the substance B would be destroyed more slowly than C. As, however, this substance gives rise to the formation of C, both substances would disappear at the same time during disactivation, the mixture existing up to the disappearance of any activity. In order to decide between these two hypotheses, other phenomena, such as, for instance, the distillation of the activity on the bodies being heated, will have to be resorted to. The authors have made some experiments in this line which are going to be published, and according to which the former hypothesis is the true one. According to this theory the inactive substance B is the one which disappears with the greater rapidity.

New Equipment for Fire Protection.—The Metropolitan West Side Elevated Railway Company, of Chicago, have recently installed a novel car equipment for fire protection at terminals and yards, of which some particulars are given in the *Street Railway Journal* of New York. It is composed of an outfit of large chemical extinguishers of the Nott Fire Engine Company's manufacture, which are housed in a fireproof car body. The car is 30ft. long and 8ft. wide, the house being 20ft. long and extending clear across the car, with a door at each end and a window on either side. The house is cased in corrugated iron, and the floor on the platform at each end is of ¼in. steel plate. In the car, at one side near the end, two duplicate horizontal pressure tanks are mounted side by side on the floor, occupying a space of 6ft. by 4ft. 6in., leaving a 3ft. passage. Through the centre of each tank from end to end runs a shaft, carrying two paddles, and terminating outside one end in a crank. In the top of each tank near the crank is a large hole, closed by a cap. Immediately under this hole the inside shaft and paddles are so bent and shaped as to form a cradle, in which the acid solder or jar is fixed while the whole shaft is rotated. This rotation of the shaft and paddles causes the acid to be spilt, and at the same time agitates the whole mixture, thus keeping up the pressure during the discharge. The water and soda are also introduced through this hole. Two 150ft. chemical hoses are provided, which can be worked singly or together from either tank, each hose line having a 250lb. pressure gauge mounted near its controlling valve. In the corner opposite the tanks stands an upright water-supply tank of 250 gallons capacity. The apparatus is operated by giving the crank a few swings and opening the valves. Only one tank is discharged at a time, the second one being reserved for discharge while the other is being refilled, thus maintaining a continuous stream. On the second pressure tank being put into action by turning its crank after the first one has been exhausted, the pressure rapidly rises, and the hose lines are cut off from the first tank and thrown on it instantly by the valves. The gas is then blown off from the empty tank by a drain valve and pipe, a fresh charge of soda is emptied into the cap-hole, a 3in. pipe with a gate-valve refills the tank with water from the supply tank, and after a few turns of the paddle crank, to stir the soda solution, the fresh acid-holder is set in, the cap screwed on, and the tank is ready for use again, the recharging being completed in four minutes. One tank will run seven minutes when supplying both hoses simultaneously at 150lb. pressure. The tests were so satisfactory that the Metropolitan Company is building four similar cars.

The Faraday Society.—In a paper on "The Hard and Soft States in Metals," read at a meeting of the Faraday Society, Mr. G. T. Beilby remarked that an exclusively crystalline theory of metal structure was insufficient to fully explain the wide range of phenomena associated, directly or indirectly, with the hard and soft states in metals. The author observed that the crystalline was not the only form of solid aggregate; the movement of the molecules in the liquid state may be so suddenly arrested that they have no time to fall into the regular formation of the crystalline state, so that the solid which results is amorphous, not crystalline. A suddenly congealed liquid may be likened to an instantaneous photograph of the rapidly moving molecules of the liquid state. As the result of the author's investigations, the view is advanced that the mechanical, electrical, optical, and thermo-chemical properties of metals, as well as the micro-structure, show that the two states are perfectly distinct phases, the soft phase, C, being crystalline and the hard phase, A, amorphous. The transformation of A into C is effected by heat, and takes place at a definite transition temperature. On either side of the transition point the various properties are characteristic and distinct; for instance, an E.M.F. of 120 microvolts may be developed in a thermo-junction of silver in the two phases. The E.M.F. falls to zero after the junction has been heated to 260deg. for a few seconds. The transformation from hard to soft is thermally irreversible, but is readily effected mechanically. This reverse transformation—soft to hard—takes place when the metal is deformed by overstrain, however slight. It takes place through an intermediate mobile phase, in which the molecules have a freedom analagous to that in the liquid phase. This freedom is produced by motion directly imparted to the molecules during the slipping of one portion of the material over another. The transformation C – M – A, while it occurs at every moving surface, does so as a rule in extremely thin layers. The layers of the hard phase which result supply a rigid casing for the unaltered crystalline elements, and thereby give a granular and cellular structure to metal which has been overstrained by having any kind of work done on it. The coexistence of the two phases in this way accounts, the author explained in conclusion, for the variety of structure which may be developed in malleable and ductile metals. The view was expressed by Dr. T. M. Lowry that the temperature which Mr. Beilby called the transition point was not a true transition point, such as exists, for example, in sulphur at 96deg. C., at which the rhombic passes into the monoclinic phase, but really the stability limit—*i.e.*, the temperature at which the mobility of the molecules enables a change which has been trying to take place all along to do so at a visible velocity.

Chemical Effects of Cathode Rays.—Dr. E. Bose, of Göttingen University, has for two years past made a close investigation of the simplest possible case of a chemical action of cathode rays, with a view to ascertaining whether or not the chemical conversion due to the rays is a purely electro-chemical phenomenon according to Faraday's law (see *Physikalische Zeitschrift* No. 12, June 15, 1904). A solution of caustic potash, saturated in the hot state, was exposed for a long time to the effect of cathode rays in a convenient outfit, allowing of an electrolyte surface of about 80 square inches being radiated upon intensely, when a reduction attended by the formation of hydrogen was noted. The amount of electricity absorbed

Digitized by Google

by the electrolyte was measured with the aid of a hydrogen voltameter under reduced pressure, this electricity being drawn off through a platinum electrode sealed into the bottom of the testing tube. As the hydrogen present in the vacuum where the discharges took place was partly dissociated into hydrogen and oxygen, a mixture of hydrogen and oxygen, containing hydrogen in excess, was withdrawn by means of the mercury air-pump, and after the gases due to this dissociation were eliminated by an explosion, the hydrogen in excess could be measured, and its pure condition confirmed. Now, in the case of the chemical effect of the cathode rays following Faraday's law—*i.e.*, being a purely electro-chemical phenomenon—the amount of hydrogen derived from the vacuum should be strictly the same as that evolved in the voltameter. A high degree of accuracy was not to be anticipated on account of the smallness of the effects and amounts of electricity in question, but the invariable result of the experiments was in opposition to the above hypothesis, 10·30 and even more times the amount obtained in the voltameter being derived from the vacuum. There must therefore be, in addition to the electrochemical action, another chemical effect of cathode rays, due, obviously, to the kinetic energy of the cathode ray particles, this hypothesis being borne out by the theoretical considerations of the author. It is shown that in the most favourable case an amount of hydrogen even 1,600 times the electrochemical amount would be obtained, but it should be remembered that in most cases the greater part of the kinetic energy of the rays is simply transformed into heat. The author thinks his experiments are likely to bring about an agreement between existing divergent views as to the chemical or physical character of the effect exerted by cathode rays, as both kinds of effect seem to be present at the same time. Similar conditions will be met with in the case of Becquerel rays, though on account of the higher *fors viva* the dynamical effect is likely to prevail much more. On the other hand, passing to slower cathode rays, the dynamical-chemical effect should play a more and more secondary part, an effect of practically purely electrochemical character being eventually noted. The author opines even other forms of electrical discharges in gases to be likely to afford interesting material for the investigation of the electrochemical effects of electrons, allowing of a theory of electrochemistry without metallical electrodes being elaborated.

Incorporated Municipal Electrical Association. The annual general meeting of this institution, with which the convention terminated, was held at Derby on Saturday. The report showed that there had been a continued increase in the membership, which now aggregates 387. The balance-sheet, which showed a slight deficit, was adopted. In the course of the year the Parliamentary Committee dealt with a large number of enquiries from corporations and individual members upon various matters affecting municipal electrical undertakings, and gave careful consideration to the Supply of Electricity Bill, taking steps to ensure that the objections it had raised to several points in the Bill would receive attention. A case of drawing instruments was presented to Mr. Hedley Howard, of Manchester, for having won the associate's prize for a paper on "Steam-Turbines and their Efficiency Compared with Reciprocating Engines," the president remarking that the paper exhibited considerable ability and originality. The election of officers for the ensuing year resulted as follows: Mr. F. A. Newington (Edinburgh), president; Messrs. R. A. Chattock (Birmingham), and S. E. Fedden (Sheffield), vice-presidents. Council — Messrs. J. K. Brydges (Eastbourne), J. Christie (Brighton), A. S. Giles (Blackburn), H. Kilgour (Cheltenham), V. A. H. M'Cowen (Belfast), Councillor Panton (Bolton), H. F. Proctor (Bristol), Alderman J. P. Smith (Barrow-in-Furness), H. Talbot (Nottingham), Alderman Bruce (Sunderland), W. A. Chamen (Glasgow, past-president), S. L. Pearce (Manchester), Councillor Sinclair (Swansea), Bailie Willcock (Glasgow), and G. Wilkinson (Harrogate). The six last-named gentlemen are newly-elected members of the Council. Alderman G. Pearson (Bristol), Mr. J. H. Rider (London), and Mr. J. E. Edgcome (Kingston-on-Thames) were unanimously re-elected to the honorary positions of solicitor, treasurer, and secretary respectively. It was agreed to hold the next annual convention at Edinburgh, and Bailie Willcock (the chairman of the Glasgow Electricity Committee) invited the members to visit the latter place for an inspection of the extended generating stations and the turbine plant, which are expected to be completed by the date of the next convention. A resolution was passed at a special meeting amending the articles of association in regard to the qualifications for membership. The new articles read as follows: "Members.—10. Every member shall come within one of the following descriptions: (*a*) the member shall at the time of his election be the chief electrical engineer engaged on the permanent staff of an electrical undertaking owned by a local authority, or the chief assistant or head of any engineering department in connection with such an undertaking of an actual or constructing capacity of not less than 5,000 kw.; (*b*) the member shall be the committee appointed by a local authority to have control over a municipal electrical undertaking within the area of such local authority, and shall be represented as regards its qualification to vote by one member of such committee. Associate members.—11. Every associate member shall at the time of his election be an electrical engineer engaged on the permanent staff of a local authority in the capacity of assistant in a position of responsibility in connection with an undertaking having a plant capacity of at least 2,000 kw. Associates.—12. Every associate shall be an electrical engineer engaged on the permanent staff of a local authority in a position of responsibility in connection with an undertaking whose plant capacity does not exceed 2,000 kw." This resolution will be submitted for confirmation at a future meeting.

Tests of Cooper-Hewitt Mercury Vapour Lamp.—The *Electrical World* of New York describes some candle-power tests of a Cooper-Hewitt mercury vapour lamp of the type known commercially as Type H-4. The lamp, which is rated at three amperes and designed for a 110-volt circuit has a tube diameter of $1\frac{1}{16}$in. and a length of arc of 45·67in. The lamp was mounted at one end of a 5m. photometer bar and enclosed in a long wooden box at right angles with the axis of the photometer bar. At the middle of the box, in line with the axis of the bar, was a 2in. by 2in. opening. The box was well ventilated so as to give conditions as near normal as possible. The illumination from a 2in. length at the middle of the Cooper-Hewitt light was measured and the corresponding candle-power multiplied by the ratio 45·67/2, the length of the light-giving arc to the length of the tube used. The lamp and box were inclined to the horizontal plane through the axis of the photometer bar by an angle of 11deg. 20min. The lamp was compared with a standardised 32-c.p. incandescent lamp. The screen used was a Lummer-Brodhun. The balance point on the photometer bar could easily be located within 1cm., although the two sides of the screen showed a great contrast in colour. In the course of taking readings the screen was, of course, reversed, and the average reading taken. In the

Digitized by Google

first of the accompanying diagrams Curve 1 represents the variation of candle-power and current; Curve 2 the variation of watts in lamp per candle-power; Curve 3 the variation of total watts per candle-power with current; Curve 4 the variation of current and volts across tube. In Fig. 2 Curve 5 represents the variation of candle-power and current; Curve 6 the variation of watts in lamp per candle-power and current; Curve 7 the variation of total watts per candle-power and current; and Curve 8 the variation of current and volts across the tube. The curves of Fig. 2 were taken when the lamp was new. The curves of Fig. 1 were taken after the lamp had been running about 24 hours. The reduction in candle-power noted is due to a coating, at first gray and afterward black, which gradually forms all over the inside of the tube. No life tests of the lamps were made, but of two lamps which had been run continuously, one burned out after 800 hours, and the other had not burned out after running 1,000 hours. The used-up lamp blackened somewhat similarly to an incandescent lamp. The immediate failure was due to the

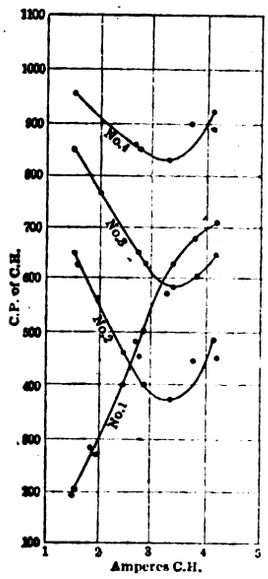

FIG. 1.

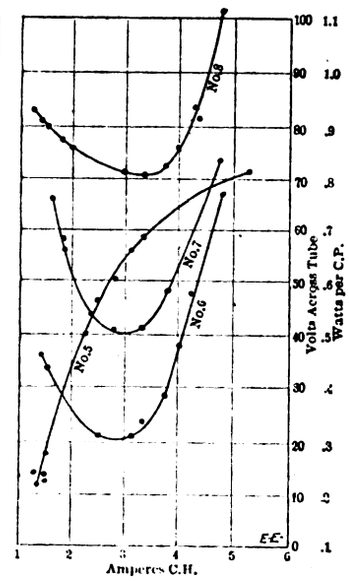

FIG. 2.

impairment of the vacuum, principally through leakage at the leading-in wires. For all curves the currents were read after the lamp had settled to steady temperature conditions, and the values used as abscissæ. All instruments were calibrated by means of standard cells and standard resistances. Curve 6 on Fig. 2 was obtained by multiplying volts across the tube by current and dividing by the candle-power corresponding to the current. It represents the watts per candle-power consumed by the lamp itself. Curve No. 7 was obtained by multiplying line volts (assumed constant at 110 volts) by current and dividing by corresponding candle-power.

The Rate Question.—A great deal of attention is being given in Germany to the question of rates of payment for electricity supply. Prof. Dr. Rasch discusses it in a recent issue of the *Electrotechnische Zeitschrift*. In his opinion the price per unit per annum, taking into account all concessions, should work out at the rate of

$$S = A + \frac{B}{T} + C \cdot n,$$

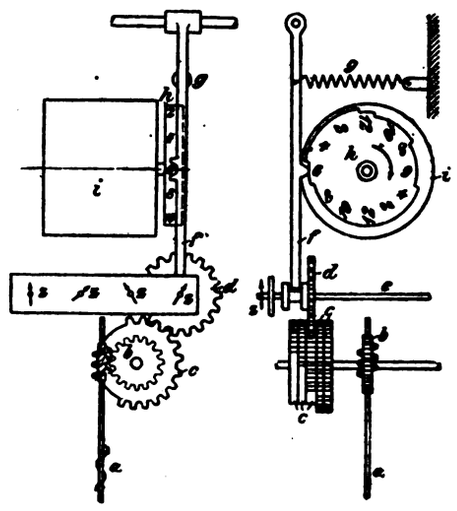
S representing the average price per unit, A B and C constants, T the mean demand $= \frac{\text{total annual consumption}}{\text{maximum demand}}$, and n the average load on the generating plant during the hours of demand. For example, suppose a consumer having a maximum demand of 2 kw. uses 200, 500, and 1,000 units at times when the load on the station plant is 100, 60, and 20 per cent. respectively. Then

$$n = \frac{200 \cdot 1 + 500 \cdot 0{\cdot}6 + 1{,}000 \cdot 0{\cdot}2}{1{,}700} = 0{\cdot}412.$$

and

$$T = \frac{1{,}700}{2} = 850.$$

The values for A B C need not be uniform for all consumers on a given supply. It may, of course, be advisable to give preferential rates to large consumers. The use to which the energy is put is of less importance than the time at which it is used. That this is now being recognised is proved by the introduction of the two-rate meter, which has already been adopted in some few instances. But while the institution of the two-rate system of payment marks an undoubted advance, it cannot be said to completely solve the question. Those who have recognised that it pays to sell current in the daytime at a cheaper rate than during the evening hours cannot deny that it could be supplied still cheaper during the night. If engineers have paused at the two-rate system it is not because it represents the acme of perfection, but rather that no cheap and reliable multi-rate meter has hitherto been obtainable. The author goes on to describe the Baumann multi-rate meter, which, in his opinion, fills the want. Accompanying are front and



side views of this meter. A motor, not shown, drives the toothed wheel, *b*, through the vertical spindle, *a*, the revolutions made by this wheel corresponding to the number of units consumed. Mounted on the same shaft with *b* are the toothed wheels, *c*, distinguished in that each has a different number of its teeth cut away, those remaining being arranged to coincide exactly, as shown, with the teeth of the companion wheels. Each of these wheels, in turn, serves to drive the gear wheel, *d*, the latter being mounted on the rectangular shaft, *e*, along whose axis it can be moved. This movement is effected through the lever, *f*, which is held in contact with the dial, *h*, of the clock, *i*, by means of the tension spring, *g*. By the movement of the dial, *h*, which occurs at intervals of an hour it follows that the gear wheel, *d*, will engage successively with the wheels, *c*, as the lever, *f*, is displaced by the steps provided round the circumference of the dial in question, a varying motion being thereby imparted to the rectangular shaft, *c*, and the attached hands, *z*. In other words the ratio of the gear through which motion is imparted to these hands is varied automatically with the time of day, hence also the price charged to the consumer for current, since the amount due from the consumer is indicated direct. A meter for, say, eight different rates costs little more than one for two rates. In conclusion, the author dilates upon the inherent possibilities of the system and points out its manifold advantages.

THE VERBAND DEUTSCHER ELEKTROTECHNIKER.

Twelfth Annual Meeting. — Cassel.

[FROM OUR SPECIAL CORRESPONDENT.]

(Continued from page 8.)

In regard to the standards for the use of electricity on ships which were approved by the meeting, as reported in the first instalment of this article, the desirability of the universal adoption of some such set of standards admits of no question. At the same time it is somewhat remarkable

Square—Old Cassel.

that it should have been left to Germany to take the lead in this matter, considering the preponderating interests of England afloat. It is, however, so far satisfactory that the importance of these standards has been practically recognised in England; the principal shipping companies having already signified their willingness to adopt them. The advantages to be derived cannot well be over-estimated. It was pointed out that their universal adoption would enable a uniform system of electricity supply to be introduced at the different ports of call throughout the world, thus enabling a ship in harbour to take a supply of current

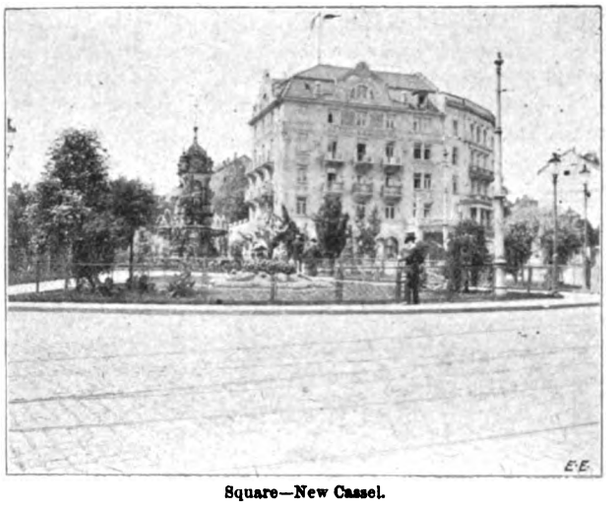
Street—Old Cassel.

from the shore station for power and lighting purposes, at a considerable saving in cost, not to mention the convenience of shutting down the ship's own plant. Moreover, the safety of ships would be increased not a little, since in the case of damage involving flooding of the boiler compartments, electric energy for driving pumps and auxiliary machines might be obtained from any steamship standing by. Or a stranded vessel might obtain current for lighting purposes in a similar manner, thereby enabling the salving of life and property by night.

Any one of the advantages enumerated is in itself sufficient justification for the introduction of these standards.

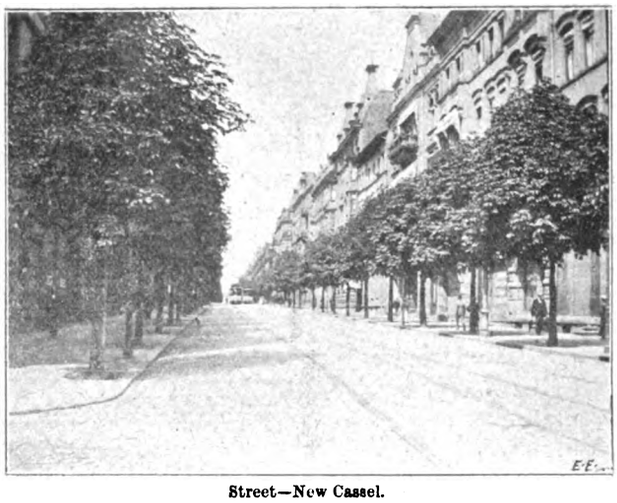
WAYLEAVES FOR TRANSMISSION LINES.

Three papers in all were contributed to the proceedings. One of these was read by Dr. Fick, of Berlin, and dealt with the question of wayleaves for power transmission lines. In the course of his remarks the author said that German legislation had maintained a wise reserve towards the new conditions which the growing importance of electricity had brought about. As a consequence, the development of the German electrical industry had hitherto been free and unhindered, while, on the other hand, that of England had been checked by the Electric Lighting Act of Aug. 18, 1882. In regard to transmission work, it was requisite that they should obtain that freedom of action so



Square—New Cassel.

essential to the continued development of the electrical industry. Not only must it be acquired in the interests of the latter, but also in that of the whole community, if the possibilities of electric transmission were to be developed for the common good. Wayleaves were already provided for in the case of Government telegraphs. What they wanted was a similar right of way for their transmission lines, thereby enabling electrical energy to be distributed as an ordinary article of commerce. As the law stood to-day it might depend, in certain circumstances, on the mood of a single stubborn landowner whether



Street—New Cassel.

a community could be supplied with electrical energy from a central station. That was an impossible state of things, and must be rectified. Streets were poorly lighted; blacksmiths, joiners, locksmiths, glaziers, all suffered from the want of a suitable supply of energy for power purposes, while hundreds of others had to make shift with oil lamps or candles, as a source of artificial light, in dwellings and places where electric light might have been established to-day, had not the projected transmission line met with opposition from some obstinate landowner, who either absolutely refused right of way, or made an exorbitant demand for the concession, thereby wrecking the scheme. Even when consent was obtained, the landlord almost invariably reserved unto himself the right to withdraw the concession. Not until the principle

Digitized by Google

of compulsory wayleaves for electric transmission lines was recognised and provided for by legislation could it be hoped that there would be any general development of the electrical industry by the erection of large works for the supply of electrical energy over wide areas. Legislation to the end in question would not only benefit already established undertakings, but also enable a large number of schemes to be carried out which were impossible now for economical reasons. In conclusion, the author hoped the Verband would do all in their power to promote the question.

In the course of the discusion which followed, it was suggested that wayleaves over public property should also be provided for by the law.

Subsequently, it was decided to appoint a special committee to deal with the question, its members to include some experts on cablelaying.

(To be continued.)

SOME NOTES ON TESTING.

BY C. H. R. T.

A good deal has been written at various times on the subject of testing, and the different tests to which dynamos and motors are usually subjected by manufacturers for the purpose of finding their efficiency, behaviour on load, etc., have many times been more or less fully described, but there are several simple little tests which are constantly made use of in the test-room, but which are never mentioned in articles and papers on the subject. Possibly it is owing to their simplicity that they are passed over, but as many of them come in very useful outside the test-room, and are not, in spite of their simplicity, too generally known among average engineers, it may be worth while mentioning a few which occur to the writer.

If a motor has to be tested, it is, of course, best to run it *as* a motor, but if current at the voltage for which the motor is designed is not available, it may be (and in practice often is) more convenient to run it as a dynamo. In the same way it may happen that no convenient means are to hand for mechanically driving a dynamo which has to be tested, whilst electrical power of the right voltage, by which it can be run as a motor is available. In the first case the motor is preferably run as a dynamo, at such a speed as to give the full voltage for which it is designed as a motor—and its speed will obviously be high. In order to find, from its behaviour as a dynamo, at what speed it will run as a motor on its proper volts, the following formula is used:

$$\frac{DS}{MS} = \frac{DV+LV}{MV-LV},$$

where DS = speed of machine running as a dynamo;
MS = speed at which machine will run as a motor on its proper volts (viz, MV);
DV = volts generated as a dynamo;
MV = volts for which machine is designed (as a motor);
LV = volts lost in armature and series field coils (if any).

In the second case, the dynamo under test is run as a motor on the voltage which it is designed to give as a dynamo, and its speed will, therefore, be low. In this case the same formula is, of course, applicable, the only difference being that the meaning of the symbols is slightly altered, they being now as follows:

DS = speed at which machine is designed to run (as a dynamo);
MS = speed machine runs at as a motor;
DV = volts machine will give as a dynamo at its correct speed (DS);
MV = volts on which machine is running as a motor;
LV = as before.

In both cases the resistance of the armature and series field coils, for calculating the lost volts, should be taken when the machine is hot after a run, but it is sometimes convenient to take a rough reading of the resistances before the run, in order to get at the size of pulleys, etc., required for the test.

Owing to the fact that when a motor is running as a dynamo, and *vice versâ*, either the speed or the volts (preferably the former) must differ somewhat from the speed or voltage for which the machine is designed, tests taken in this way are not absolutely reliable, but the error is usually very slight, and for most purposes negligable.

In compound motors and dynamos, it is often difficult to see which way the two coils on the bobbins are wound, and consequently they are often coupled up for testing with the series winding opposing the shunt. This, if at first overlooked, is generally noticed on starting up in the case of a motor, or in putting the load on in the case of a dynamo (or a motor which has started up all right). When, however, the amount of series compounding is comparatively small, a machine may often be started up and loaded without anything uncanny happening, and the high speed in the case of a motor, or low voltage in the case of a dynamo (neither being very marked), may be put down to faulty calculations on the part of the designer. If there is any doubt about the matter, a convenient and much-used way of satisfying oneself is to short-circuit the series winding for a few seconds, and observe the result on the load. In the case of a *dynamo*, the load—*i.e.*, external amperes—goes *up* if the series winding *opposes* the shunt, and it goes down if the machine is correctly coupled. In the case of a *motor*, the load—*i.e.*, the external amperes of the driven machine—goes *down* if the machine is *wrongly* coupled, and up if it is correct. The reason is obvious. The test is, of course, never required with heavily compounded machines, as the "nigger" will be discovered before getting much load on.

It is usual in manufacturing works to send machines in to be tested when they are in the rough state and not coupled up, in case any alterations are required in the windings. Although, therefore, a machine may have run correctly on test, it is not safe to send it away without a final inspection and coupling-up test by the test-room officials. These coupling-up tests are, of course, very simple, but mistakes are nevertheless sometimes made in carrying them out, and it may, therefore, be of some service to mention the points to be noticed. In these tests it is only necessary to run the machines round for a few seconds without any load, and the quickest and simplest way of doing this is to connect them up to an electrical supply and run them round as motors, even if they are going out as dynamos.

In the case of shunt and series motors these tests are very simple, as they should, of course, run in their proper direction if coupled up correctly. Compound motors should be run on the two windings separately—*i.e.*, the machine should be first run as a shunt motor, the series winding being short-circuited or cut out, and then as a series motor, the lead from the starter to the shunt terminal of the motor being left out. Both on the shunt and the series windings the machine will run in the proper direction if correctly coupled up.

In the case of dynamos a little more attention is required. Shunt dynamos, if correctly coupled up, will run as motors in their proper direction, but *series* dynamos will run in the *wrong* direction, or against the brushes. Compound dynamos will therefore run in their proper direction when running on the shunt winding only, and in the *wrong* direction on the *series* winding if correctly coupled up.

For these coupling-up tests it is most convenient to have supply mains of fairly low voltage—say, about 100 volts—laid on in a handy place so that all machines above that voltage may be run on them. Very low-voltage machines are scarce, and special arrangements must be made when they come along for their final test. In running, say, a 500-volt shunt machine on 100 volts, it will often require a push round by hand to start it, but once started, care must be taken that it does not attain a dangerous speed, owing to its weak field. The same also applies, of course, to running a series machine, or a compound machine with the shunt disconnected, on no load. If gauze brushes are fitted on a series or compound dynamo, it is advisable to only let the armature make one or two turns, or even only part of a turn, in the wrong direction, as otherwise the brushes may be damaged.

Digitized by Google

When running shunt or compound dynamos as motors, one end of the shunt-winding must, as a rule, be temporarily disconnected from a main terminal, in order to connect it up to the "shunt" terminal of the motor-starter; but this temporary alteration to the final coupling up of the dynamo cannot, of course, affect the direction of rotation. In many cases provision is made on the dynamo for the insertion of a regulating rheostat in the shunt circuit, and then no alteration whatever has to be made in the connections when making the final test.

INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

Ninth Annual Convention.

(Continued from page 16.)

Commercial Practicability of Electric Traction by Surface Contacts.

BY C. E. C. SHAWFIELD, A.M.I.E.E., M.I.MECH.E., BOROUGH ELECTRICAL AND TRAMWAY ENGINEER, WOLVERHAMPTON.

(Concluded.)

In the case of the Lorain system as installed at Wolverhampton, the current required for the operation of the circuit-closing mechanism in the track equipment, which is in this case the energy required for the excitation of the magnets, represents a power consumption of 670 watts per hour, which is equivalent, under ordinary conditions of service, to ·11 unit per car mile. The additional energy required to propel the cars owing to the extra weight carried must, of course, vary in different localities, being obviously more in a hilly district than in a flat. It would also be affected to a certain extent by the type of rolling-stock in use and the distance apart of the stopping places. It is therefore impossible to give a general estimate as to the additional energy consumed under this heading. In Wolverhampton the routes at present in operation include some rather severe gradients, and owing to the fact that a large proportion of the road surfaces in the vicinity of the routes are macadamised, the track is always very muddy and greasy in wet weather, and correspondingly dusty in dry weather. The tendency is therefore for the current consumption per car mile to be rather heavy, the average during the past 12 months being 1·49 units. The average total weight of a single-truck double-deck car, together with driver and conductor and an average number of passengers, but *exclusive* of Lorain equipment, is 8¾ tons. To this must be added the weight of the magnets, collecting skate, battery, cables, and connections of the surface-contact apparatus, amounting in all to one ton. The steepest gradient has a rise of 1 in 17, and there are a number of sharp curves varying from 40ft. to 37ft. 6in. radius. Under these conditions the author has calculated that the additional current consumption due to the weight of the Lorain equipment is approximately equal to ·13 unit per car mile. The *total* additional current consumption to be debited against the surface-contact system is in this case ·24 unit per car mile, or approximately 19 per cent. in excess of what would have been required by the overhead system.

Cost of Installation.

Although perhaps not of such vital importance as the cost of operation, yet nevertheless the capital cost of installation must weigh heavily in considering the merits of any system, and it is obvious, therefore, that any system of electric traction which desires to enter into competition with the overhead trolley system must be capable of being installed at a cost not very much in excess of the latter. It is very difficult, if not impossible, to give a general figure for the difference in first cost of the overhead system and the surface-contact system, owing to the fact that whilst the cost of the former is practically the same for either double or single track, the cost of the electrical equipment of the latter is obviously twice as much for double track as for single. Consequently the amount of the extra cost of installing a surface-contact system necessarily depends upon the proportion of double to single track on the routes concerned. Speaking generally, however, it may be taken that first-class overhead construction costs from £1,500 to £2,000 *per mile of route*, whether double or single, whereas the cost of the surface-contact system will be from £2,000 to £2,500 *per mile of single track.*

Disfigurement of Streets and Obstruction to Traffic.

It seems at the present time to be almost an article of faith amongst those in charge of the promotion of tramway schemes that the adoption of electric traction must of necessity involve the disfigurement of the streets, either by the erection of tramway poles and overhead wires or by the construction of an open slot between the centre of each track. It is true that great progress has been made in the direction of rendering modern overhead construction less unsightly and obtrusive than was the case formerly, but, nevertheless, it must be generally admitted that the introduction of the overhead system into towns like Manchester and Liverpool has to a very large extent spoilt the appearance of some of the finest streets and buildings in those cities. One has only to compare the present appearance of St. George's-square, Liverpool, or Piccadilly, Manchester, with what it was before the introduction of electric traction to realise the great disfigurement due to the erection of poles and wires along these fine thoroughfares. The author was speaking not very long ago to a Liverpool photographer, who informed him that at the present time it is practically impossible to get a satisfactory photograph of St. George's Hall from any point of the compass owing to the interposition of the network of overhead wires. Where centre-pole construction is in use, there is, in addition to the unsightliness involved, another very serious objection—namely, the obstruction to traffic. There can be no doubt whatever that the introduction of centre poles into a street of average width very largely reduces the accommodation for vehicular traffic, and materially adds to the congestion of the already overcrowded streets in many of our large towns. Where side-pole construction is adopted, this inconvenience is not so marked, although the presence of a large iron pole with massive base every 40 yards along the side walk is not by any means conducive to the comfort and convenience of pedestrians.

It is claimed for the surface-contact system that it offers less impediment to the free use of the streets and side walks than any other system of electric traction in which the energy for the propulsion of the cars is collected from an external source, and the experience of the author in connection with the Wolverhampton tramways leads him to believe that this claim is justified. It was anticipated when the system was first installed that trouble would be experienced through the metallic studs between the rails projecting above the normal level of the paving, proving a source of danger to the ordinary street traffic and to horses in particular, and that considerable expense would be occasioned through the extra wear and tear of the paving surrounding the studs. During the 2½ years that the system has been in operation no complaint of any kind has been received as to any obstruction or inconvenience to traffic having been caused by the iron top plates in the street surface, and, so far as the author is aware, no accident of any kind has ever been attributed to them. There is, moreover, no indication of any abnormal wear of the paving surrounding the studs, neither wood nor granite paving in the immediate vicinity of the metal top plates appearing to wear any faster than at any other parts of the track. On the score of appearance it may fairly be said that the surface-contact system is the least conspicuous and the least objectionable of any system of electrical traction; in fact, it is the author's experience that unless the track is abnormally clean and free from dirt it is very difficult to distinguish the studs from the remainder of the paving. During dusty or muddy weather it needs a close examination of the track to detect the exact whereabouts of the metal top plates, and probably owing to this reason a very large proportion of visitors to the town go away with the impression that the electric energy for the propulsion of the cars is carried in storage batteries on the cars themselves. There can be very little doubt that from the point of view of the property owner in good residential districts, the surface-contact system is distinctly preferable to the overhead system, as it is much less likely to cause depreciation in the value of the property adjoining the tramway routes. To illustrate certain points raised on this question of disfigurement of streets and obstruction to traffic, the author hopes to be able to exhibit several lantern slides of streets in Wolverhampton where the Lorain surface-contact system is in use, and of similar streets in other towns where the overhead system is installed.

In considering the results achieved at Wolverhampton in the operation of tramways by a surface-contact system, it should be borne in mind that in many respects the local conditions at Wolverhampton are probably more unfavourable to the successful operation of a surface-contact system than in almost any other town in the United Kingdom. Owing to the large number of factories in the town engaged in the production of stamped steel and iron articles, a very large quantity of scrap iron of all sorts and sizes is produced and has to be carted away from the various works. This scrap iron is usually very carelessly heaped in open carts, with the result that a considerable percentage of each load is scattered in the streets, and it unfortunately happens that the principal repositories for scrap iron are situated on the busiest tramway routes. As previously explained the presence of this scrap iron constitutes the most serious difficulty the system has had to contend with. The heavy rainfall of the last two years, in conjunction with the very general use of macadam in the majority of the streets in the town, has resulted in a clean track being a luxury but rarely attained, the track being usually covered with a sticky mud, which an hour or two's wind and sun speedily converted into equally objectionable dust. It should be pointed out, moreover,

Digitized by Google

that in Wolverhampton the track is laid to a 3ft. 6in. gauge, and consequently the space available between the rails and between the side frames of the trucks for the reception of the surface-contact apparatus is comparatively limited, and the author believes that with the standard 4ft. 8½in. gauge many of the troubles experienced with the upkeep of the magnet and collecting skates would largely, if not entirely, disappear, and the arrangement of the track equipment at points, crossings, and other special track work would be considerably simplified.

The conclusions arrived at in the foregoing paper may be briefly summarised as follows: A well designed and carefully installed surface-contact system is superior to the overhead trolley system in respect of the questions of safety, reliability, disfigurement of streets, and obstruction to traffic. The overhead system is considerably cheaper both as regards the capital cost of installation and the annual cost of operation and maintenance. For tramway systems where low initial cost and low annual charges are the first consideration, and especially for light railways in thinly-populated districts, the overhead system is to be preferred. In many of our larger towns, and especially at watering places and other pleasure resorts, the surface-contact system has many claims for serious consideration in preference to the overhead trolley system. The author has made no attempt to treat this subject at all fully in the limited scope available in a paper of this discription, his object being merely to provide a basis for discussion of a subject which has previously been brought very little before the notice of tramway engineers as a body.

Discussion.

Mr. J. H. Rider, of the London County Council, opened the discussion, and congratulated the association on having such an excellent paper from Mr. Shawfield. Wolverhampton was the only town in the British Isles which had a surface-contact system of electric traction, and Mr. Shawfield was the only engineer who was able to give them his experience of working such a system. He asked the author how he arranged his car-sheds, as he did not see that there could be the pits which were required below all the tracks for inspection purposes. As regarded safety, which was the all important question, Table I. showed that there were on the average 21 studs alive per mile of roadway per annum. No system of overhead construction would be permitted with such a record. With respect to the trouble from scrap iron on the track he thought that Wolverhampton was the last place in which to try a surface-contact system. A parallel case was that of the first conduit line at Blackpool. The local conditions interfered with the working and threw back the development of the conduit system in other places. He then quoted the following extract from the paper: "The author has on more than one occasion watched a pedestrian step on a box which he has known to be alive at a pressure of 500 volts, as recorded by a Weston voltmeter, but in all cases the individual was apparently quite unaware of the fact." A little farther on the author stated that with falling trolley wires and lines and "live" tramway poles occurring frequently on the overhead system, the absence of injury to human beings and animals appeared "to be largely due to the beneficent interposing of providence." Mr. Rider thought that providence was a new name for a thick and dry leather sole, but he did not fancy a system which made the engineer so careless as to stand and watch pedestrians stepping on a live track. The author's comparisons of the overhead system and the surface-contact system were not fair, because there were 100 overhead lines to only a few equipped on the surface-contact system. Without doubt, trolley poles and the tramway poles in the streets should always be earthed up, but this could not be done with the studs of the surface-contact system, and there was absolutely nothing to show whether they were alive. Referring to the effect of a breakdown on one stud, Mr. Rider proceeded to argue that this would cause the current to be interrupted at the carbon contact in the previous switch, and that in consequence there was more chance of studs being left alive. He said that the author's remarks on the faults of overhead system were only applicable to cases of very bad design, he knew of no case where single insulation of the overhead wires was used. It seemed to the speaker that the heavy skates under the car hampered access to the motors. He concluded his remarks by repeating a conversation he had recently had with a Wolverhampton gentleman. This gentleman said that he was very pleased with the tramway system, and that they had the quickest service he knew of. It was due to the fact that the horses and carts always kept off the tracks.

Mr. Wedmore, of the Lorain Company, who spoke next, said that they preferred to try their system under the worst possible conditions, as if it was successful in Wolverhampton it would be much more successful in other towns where the conditions were better. He thought that the scrap iron which had caused trouble in Wolverhampton would also have seriously upset the conduit system of the London County Council. Wolverhampton had the only commercial system of electric traction by surface contact, and Mr. Wedmore proceeded to review the troubles which had prevented the continuation of the use of rival systems in other places. Mr. Rider was wrong in his supposition that the armature might be held up by friction, as the design of the apparatus absolutely prevented any friction between the carbon contacts. With respect to the weight of one ton of the magnet and skate, this compared with the half-ton of the plough on the conduit system. He had calculated that the extra electric energy required for moving this extra one ton per car was more than was required to excite the magnet.

Mr. Raphael commented on the lantern slides of overhead work which had been found on the screen. His experience of photographs of overhead construction was that the wires were difficult to see, and they always had to be thickened up before they could be used for reproduction purposes. He had never seen, however, a case in which this thickening up had exaggerated the appearance of the overhead wires as much as in the author's lantern slides. (N.B.—This invisibility of overhead wires in photographs is due to an halation effect with which all amateur photographers are conversant.—Editor *E E.*)

Mr. J. F. C. Snell (of Sunderland) confined his remarks to questions to which he would like further information. For instance, he wished to know the average leakage and how this complied with the Board of Trade requirements; how long it took to place a defective box, and whether they had trouble with horses sliding on the studs. If Mr. Rider's story was a true one, he congratulated Mr. Shawfield on being able to keep horses off the track. At Sunderland they had to bear on the average an expense of about £50 per annum per mile for repaving the tracks owing to wear. This was out of a total of £74 per annum per mile. If Mr. Shawfield with the surface-contact system was able to reduce this charge, it would go towards the extra capital charges on the cost of the system.

Mr. Stanley Clegg (Lincoln) was interested in the paper because they had practically decided to use the surface-contact system in the city of Lincoln. They were inclined to favour the Griffiths-Bedell system. He would like to know what was the drop in volts between the live cable and the motor terminal. He thought that Mr. Rider was wrong in his remarks as to the effect of a faulty stud, as all the arcing would take place at the road surface and not in the switch. The author in Table IV. had given the cost of repairs and maintenance of the track equipment at £21. 6s. per mile of single track. He had recently obtained from 30 different towns this cost for the overhead equipment, and the replies ranged from £5 to £95 per mile.

Mr. G. E. C. Shawfield, in reply, said that in their new car depôt they were having inspection pits under all the tracks. They found the best way of moving the cars in the shed was by means of a wandering lead. They had not had any extra labour in consequence of the increased difficulty of inspecting the motors and gearing under the car. The 119 studs which had been found alive in the course of a year rather exaggerated the matter, as although they were alive a shock could not be got from them for reasons explained in the paper. He thought that Wolverhampton was the best town in which to try the system. The studs were only found alive after a short-circuit, usually due to scrap iron, had occurred on the street surface. The small boys with bare feet made a practice of investigating the studs whenever they saw the flash under the car, in order that they might run to the power station and claim a small reward for reporting the live studs. In the same way the conductor, after a short had occurred,

Digitized by Google

always went to feel the studs to see if they were alive, and in no cases had accidents occurred from this practice. He would inform Mr. Rider that, from his (Mr. Shawfield's) experience, the British Electric Traction Company used single insulation on the majority of their overhead work. Mr. Rider was wrong in his supposition that with one defective stud the current would be broken at the carbon contacts of the switch. The magnets held up the contact in this case until the circuit was broken at the street surface. He knew of 50 miles of track owned by the British Electric Company on which the troubles from this system mentioned in his paper obtained. In reply to Mr. Snell, he said that in dry weather the leakage current per car was inappreciable. In extremely wet weather, again, it was not more than one-tenth of an ampere. When the streets were extremely muddy, it was anything from 1 to 1½ amperes. The average leakage over the year worked out at about 0·008 of a unit per car mile. They could remove a box easily in 15 minutes and replace it with a new one; he could do it in 10 minutes. There was no need, however, to replace these boxes in the daytime, as the leakage was so small that they could be left in until the night. In the course of 2½ years they had had no accidents from horses or pedestrians sliding on studs.

The Organisation and Management of a Central-Station Meter Department.

BY A. J. CRIDGE, SHEFFIELD.

The object of this paper is to outline some of the methods adopted in the equipment, maintenance, and working of a meter department in connection with an electricity supply undertaking. In small stations it is usual for the mains engineer to take charge of the testing and installation of the meters required, but when the system has increased to a sufficient extent, it will be found advisable to start a separate department to deal with this work.

In describing the arrangements of the work of a meter department it will be convenient to divide it under heads, thus: I. Work in connection with meters. II. Work in connection with instruments and general testing. III. Work in connection with consumers' installations. IV. The commercial and clerical side. These heads may be further divided, as follows: I. Work in connection with meters includes (1) testing and calibrating meters; (2) fixing meters; (3) reading meters; (4) the maintenance of the station meters in a satisfactory condition. II. Work in connection with instruments and general testing includes: (1) testing and calibrating voltmeters, ammeters, etc.; (2) testing resistances; (3) testing lamps for candle-power, efficiency, and life; (4) testing appliances, such as fuses, switches, etc., when submitted for approval. III. Work in connection with consumers' installations includes: (1) the examination of new wiring while in progress on consumers' premises; (2) testing and connecting such wiring when satisfactorily completed; (3) attending to complaints of poor light, extinctions, etc., received during the daytime. IV. The commercial and clerical side includes: (1) entering up the monthly readings of the consumers' meters and making out the accounts ready for the general office; (2) keeping the records of the installations of all the consumers, noting alterations, disconnections, etc.; (3) keeping the meter stock, meters changed, reports, work, and other books of the department; (4) attending to consumers' complaints of accounts; (5) the consideration of any application for the supply of electricity at reduced rates, or for discounts; (6) the allocation of wages, expenses, and costs in connection with the department; (7) buying meters and looking out for the newest and best that are on the market.

A description of a system of interdepartmental working in use at Sheffield and some other towns may possibly be of interest, but as it is not entirely the work of the meter department it has not been placed under any of the foregoing heads. It will now be convenient to consider the internal equipment of the test-room. The test-room should be provided with sufficient shelves for storing meters; nothing is worse than to have meters on the floor or piled upon each other. There should be plenty of spare bench room, and a small vice attached to the bench is very handy.

I.—Work in Connection with Meters.

1. For the purpose of controlling the supply of electricity for testing a switchboard will be required. The one here described controls a maximum supply of 10 kw.—*i.e.*, 50 amperes at 200 volts single-phase alternating current. By means of a suitable transformer it is possible to get almost any voltage from 28 to 300 by altering the connections. This is done by causing the turns on the secondaries of the transformer to help or to oppose each other. Similarly, it is possible to get any current up to 300 or 400 amperes. The link connectors of the transformer therefore give a coarse adjustment, and the fine adjustment is made by means of suitable rheostats. The voltage is measured by Kelvin voltmeters, the current by Kelvin ammeters, and the wattage by a Kelvin balance. There are six main circuits, which branch off from the switchboard as follows: (1) experimental, (2) rheostat (large), (3) rheostat (small), (4) meter bench (one), (5) meter bench (two), (6) main coil of Kelvin balance. These are put in or taken out of circuit by plugs, and the ammeters are connected by plugs with flexible conductors attached. There are 12 pressure circuits provided, six on either end of the board. Only four of these are in use on one end and three on the other. They are as follows: I. (1) meter bench (1) top shunt circuit, (2) meter bench bottom shunt circuit, (3) experimental, (4) photometer; II. (1) meter bench (2) top shunt circuit, (2) meter bench bottom shunt circuit, (3) shunt of Kelvin balance. Two-pin plugs are placed across each of the main circuits for the purpose of measuring the pressure between any pair of circuit leads or absorbed in any piece of apparatus. The use of the main circuits is: (1) Experimental.—A pair of heavy cables run to a pair of big terminals on a bench. The current and the pressure can be adjusted to any figure desired, so that the circuit may be used for any purpose. (2) Rheostat (large).—This is for the control of currents up to 125 amperes. It consists of carbon plates, and the resistance is increased or diminished by slackening or tightening a screw. (3) Rheostat (small).—This is for the adjustment of small currents, from ·1 to 5 amperes. (4) and (5) Meter benches.—These are arranged to hold a total of 48 meters. The meters are placed in position on the bench and the series coils are disconnected from the shunt coils. The series coils are then connected to terminals on the bench by flexible connectors and the shunt coils joined across the proper pressure circuits by small flexibles, to which are attached two-pin plugs. Attention has been given in the design of these benches to the need of fixing up a number of meters for testing in the most expeditious manner possible. All connections are made by plugs or clips. To join up any terminals not in use, copper bridge pieces are employed. (6) Main coil of Kelvin balance.—The balance shunt coil is disconnected from the current coil, and the latter, which constitutes circuit 6, is plugged in in series with the meter benches and rheostats. The shunt coil is connected across pressure circuit II., sub-circuit 3. The use of the pressure circuits is almost obvious. On circuit I. the first two sub-circuits are for the shunts of meters connected to the top or bottom racks of meter bench I. The third sub-circuit consists of a pair of leads which run to two terminals on the working bench, and to which may be connected any apparatus which does not take very much current. The most frequent use to which it is put is that of running incandescent lamps which are undergoing a life test. Sub-circuit 4 belongs to the photometer, to which reference will be made under the heading II. 3. Two sub-circuits are not yet in use. On circuit II., the first two sub-circuits supply the shunts of meters on meter bench II., and the third is the shunt of the Kelvin balance. There are therefore three spare ways on this circuit. The testing of meters is carried out as follows. A number of meters having been joined up in series on the benches with their series coils disconnected from their shunt coils, the current flowing through them is adjusted by means of the rheostats and measured by the balance. A few revolutions of the disc are observed, and the time taken is noted by means of a chronograph. The testing constant of the meter being known, the percentage accuracy can be calculated from these observations. The practice seems to be becoming general among meter makers of constructing all their meters in such a manner that the disc revolves a certain round number of times per minute at full load. Thus Ferranti meters make 40 revolutions per minute at full load, Westinghouse and Schuckert 50, Electrical Company 60. Other makes of meters have a constant marked on the dial, giving the number of watts which cause the disc to make one revolution in an hour. Thomson-Houston meters form a well known example of this kind. A few words on the different kinds of meters will not be out of place here, but it is difficult to say anything new on this subject. The object of this paper is not to say which type of meter is best nor to go into many constructional details. It will suffice to say that any induction meter which is suitable for inductive as well as non-inductive load is usually good. The day of meters with commutators is over; there are now so many good types of induction meters which are greatly superior if only for this reason. The Aron meter is good, but the winding gear has been found to give a lot of trouble on alternating-current circuits; the contacts get dirty because of the sparking which takes place so frequently. Some meters are now constructed with cyclometer dials, and most manufacturers are willing to supply their meters fitted in this way. These are infinitely to be preferred to the old type; the possibility of error on the part of the meter reader is entirely eliminated, and consumers like them because they are easier to read, and they are thus enabled to check their consumption. It will be seen by making a small calculation that testing meters

Digitized by Google

as described above is far more economical than the old-fashioned method of using a bank of lamps. A 10-ampere meter under the old method required two kilowatts at full load, the pressure being assumed at 200 volts. By the use of the transformer we have 10 amperes at 28 volts = 280 watts, plus, say, four to six watts in the meter shunt, or a saving in power of nearly 87 per cent. This saving will amount to a considerable number of units during a year.

2. *Fixing Meters.* — The meter, after being tested and adjusted, is sent out to an installation. The meter reader has to note the reading of the old meter, take out the fuses, take down the old meter and fix the new one, replace the fuses, note the reading of the new meter, and try it for starting with an 8-c.p. lamp. If it is a new installation, he has not to put in the fuses nor to try the meter, this being the duty of the testing inspector.

3. *Reading Meters.*—This will be described under IV., 1, referring to consumers' accounts.

4. The maintenance of the station meters is an important matter, and they should receive frequent attention. It is useful for many reasons to know the total number of units generated; the works costs, percentage of waste, etc., are all determined from this total. A small error in large meters such as these makes a lot of difference, and great care should, therefore, be taken that these meters are kept in an accurate and satisfactory condition. Demand indicators are not in use at Sheffield, but for the purpose of testing these a circuit would be run to a suitable rack, and the indicators would be connected in series and set to zero. The required current would be passed through them for 30 or 40 minutes, and readings would be taken. The necessary adjustments would be made from these observations.

II.—Work in Connection with Instruments.

1. *Testing and Calibrating Voltmeters, Ammeters, etc.*—Any instrument which needs testing is connected across the experimental circuit in series with a rheostat and a standard instrument, and comparisons are made at a number of points in the range. No detailed description of this work is necessary.

2. *Testing Resistances.*—A Wheatstone bridge is the best thing to use for this work. The Vulcan ohmmeter is a cheap and useful instrument, the range being from ·1 ohm to 20 megohms, and the method of using the instrument is the same as the bridge.

3. *Testing Lamps.*—It is very useful to be able to test the candle-power and wattage of lamps, and to know the best lamp to recommend for consumers' use. One of the pressure circuits is in use for this work. A voltmeter, ammeter, and rheostat are connected on this circuit, together with the lamp to be tested. The standard light is a Simmance's 1-c.p. pentane lamp, and the comparisons are made on a direct-reading scale by means of a Bunsen disc. The photometer should be constructed for use in a light room, as space cannot often be spared to build a dark room. The results obtained by careful use of the photometer are very reliable. They agree closely with independent tests made elsewhere, although lamps often come out rather worse than the makers advertise. The lamps are put on for life test in a bank constructed to hold 25 at a time. Tests of the candle-power, etc., are made at intervals of 24, 100, 250, 500, 750, and 1,000 hours. The reason for the test at 24 hours is that some lamps increase in candle-power after they have been running a little while. It is frequently supposed by non-technical people that the energy taken by a lamp increases as time goes on. This, of course, is not the case; the total watts fall slightly, but as the candle-power falls more quickly the watts per candle increase.

4. Not many appliances for use in consumers' installations are submitted, but when they are offered for examination, tests are made under both normal and abnormal conditions. For switches, fuse-boxes, etc., the abnormal conditions are to operate on double their stated capacity at double the proper pressure. The testing of time switches, prepayment devices, etc., may be placed in this division. Two types of time switches which have been submitted for testing may be noticed with advantage. One, known as the tariff contractor, was designed for opening and closing the shunt of the second meter on two-rate systems. It is not intended for use on large circuits. It consists of a clock, driving two cams, which can be set to act at any desired times. When the proper time arrives the first cam causes the contact to spring together, the shunt of the meter is closed, and it registers. At the end of the peak time the second cam comes into operation and the circuit is broken. The second time switch, submitted by a Birmingham house, was operated by two clockwork movements, one of which indicated the time, while the other came into action when released at the time at which the switch was desired to operate. This second clock is driven by a powerful spring, and lifts the switch up or pushes it down by means of a connecting rod and suitable gearing. The few prepayment meters in use in Sheffield are of the vulcan type—1d. in the slot—which have proved quite satisfactory. The penny is inserted, and the handle turned until the coin is heard to drop, when the switch is closed, and the spring wound up to a certain amount. Eight pennies can be inserted at one time. Sixpence per unit is charged for current supplied through prepayment meters, this includes meter rent. The revolution of the meter armature causes the spring to unwind gradually, and when all the energy prepaid has been consumed, the circuit is broken. Practically no

trouble has been experienced with any of these meters since they were installed, with the exception of one or two cases where bent coins have been used.

III.—Work in Connection with Consumers' Installations.

1. *The Inspection of New Wiring while in Progress on Consumers' Premises.*—This is an important part of the duties of the testing inspector. It is difficult to make a thorough inspection of a completed installation; consumers naturally object to having floor boards lifted, capping taken off, etc., when the job has been finished off. It will therefore be found advisable for the inspector to visit new installations while actually being wired, when joints can be examined, samples of cable can be taken, the methods adopted for laying concealed wires can be enquired into, and any other examination can be made. By this means it can usually be assured that the job when finished will be satisfactory, and that all parties will be saved the inconvenience and annoyance entailed by repairs having to be made.

2. *The Testing and Connecting of New Installations when Satisfactorily Completed.*—After the inspection referred to in the preceding paragraph, very little remains to be done except to test the insulation resistance to earth and between leads. There are, it is well known, several ways of doing this. A convenient way is the use of Evershed's ohmmeter and generator, but it is more satisfactory to use the current from the town mains when possible. By this means any possible defect in the generator of the testing set, causing it to give less than the required voltage, is removed. Recently a useful little testing set has been introduced for use on alternating-current mains. Its only fault is that the top reading is only one megohm. It can be made to transform up to double the pressure on the mains and thus comply with the I.E.E. rules. When short-circuited it may be used as a voltmeter. Testing on direct currents may be carried out on the town mains with a Silvertown set, using a 5-c.p. lamp in series, or with a Kelvin set. This is obviously open to the objection that the test is carried out at the declared pressure, instead of twice that amount. In testing on the town mains with direct current, care must be taken to connect the set up properly, or the reading will simply show the resistance of the instrument itself, and not the insulation resistance to earth. The use of batteries is objectionable; they are messy and unreliable, besides which they are awkward things to carry about when they are made for 400 or 500 volts. The insulation test, then, being made, main fuses of the proper size are put in, the main switch is turned on, and all the lamps and other consuming devices are tried to see if they are in working order. The inspector should also try the meter for starting before leaving the job. It will be found convenient to test the amperes on the distribution circuit for a final check. It is not always easy to find the exact number of points on a circuit before the job is completed. For this purpose any small ammeter may be used; one of the watch pattern, reading up to five amperes, is sufficient for installations of incandescent lamps.

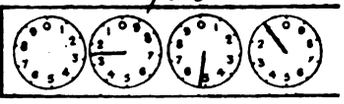
3. *Attending to Complaints of Poor Light, Extinctions, etc., Received During the Daytime.*—In the case of a complaint of poor light, it will be advisable in most cases to send up and see if it is possible to advise the consumer to make any little alterations to the distribution of his lamps, or to put in new lamps. This, of course, is in addition to taking pressure tests. It may be found that a consumer is using three five-light fittings in a shop where 10 lights placed in the proper positions would give him a better result and cost him less money. It is necessary to send a capable and tactful man on work of this kind. Extinctions may be attended to by meter readers, as they are generally due to a fuse having blown for some reason. The instructions given in the Sheffield meter department are as follows: (1) a form must always be taken and the consumer's signature obtained before commencing work; (2) the Corporation's apparatus must first be inspected and afterwards the consumer's installation—defects must be rectified as far as possible, and a full report made on the fuse form; (3) the new fuse inserted must always be of exactly the same size as the fuse blown, and if the new fuse blows it should not again be replaced. On the form referred to the consumer applies to the manager to remedy failure of electric light at premises situated ————, for which service the consumer agrees to payment of a fee, which is 1s. or 2s. 6d. according to circumstances. The inspector makes his report on the same form, and it is handed to the meter superintendent, who decides whether a charge is to be made or not and sends it down to the general office. The third instruction is given in order to ensure that no additional lights are connected without the knowledge of some of the staff. It will be noticed that the meter reader is not allowed to increase the size of the fuse, and thus neither can extensions be connected nor faults burnt out by the insertion of an excessive fuse. During the evening fault work is attended to by the mains department, but the procedure is similar in every way to that of the meter department described above.

IV.—The Commercial and Clerical Side.

1. *Entering up the Monthly Readings of the Consumers' Meters and making out the Accounts ready for the General Office.*—The procedure during meter reading will be readily understood from the following extracts from the meter inspectors' instructions. It should be understood that dial cards are used for taking the readings of the meters.

STREET East Street N° 99.
NAME Smith, J.
METER N° 123456 K 1
10/200

DATE 22-4-04



1. Meters must be read in the exact order in which the cards are placed, and each circuit must be completed before commencing another.
2. The exact position of the hands of the meter must be sketched on the reading card, commencing with the unit dial on the right hand; if a meter has more than four dials the reading of the others may be put down in figures at the left of the card.
3. The readings of meters must be entered on the consumer's meter cards with the date of reading, and initialled by the inspector. Readings should be compared month by month, and any abnormal increase or diminution in the consumption should be reported, in order that the same may be enquired into.
4. Each meter must be tried for starting with one 16-c.p. lamp, and any meter not doing so must be tried with more until it does start.
5. The number and size of any meter running on shunt, not starting with one 16-c.p. lamp, or being otherwise defective, must be taken, and entered in the report book the same day as found.
6. All Corporation seals on cut-outs, meters, etc., must be intact, and the Corporation's "Caution" label must be on every meter. Anything contrary to this rule must be entered in the report book the same day as found.
7. Inspectors must not make any remarks whatever on the state of the Corporation's apparatus or of the consumer's installation. All enquiring consumers must be referred to the office.

The monthly reading takes about 10 days. It is commenced every fourth Monday, so that there are 13 readings in the 12 months. Entering the readings up and settling the queries takes about 14 days. The readings are entered on account cards. The cards are arranged in the most convenient order for reading, and the town is divided into districts. Four men are engaged meter reading, and these follow each other on the different circuits every month: thus in January, A would take circuit 1, B circuit 2, etc.; in February, A would take circuit 2, B circuit 3, and so on. In this way each inspector checks the man who preceded him, and the perpetuation of errors is avoided. If the clerk considers any reading doubtful, he notes the name and address of the consumer with the suspected nature of the fault, and the foreman meter reader examines the meter, checks the reading, and decides whether or not the meter should be changed and tested. When all accounts are entered up and queries settled, the cards are sent down to the general office, where the invoices are made out and the ledgers entered up. Reading and account cards are ruled on both sides.

2. For keeping the records of consumers' installations cards are used giving full particulars.

3. It is almost impossible satisfactorily to keep meter stock records in books. It is better to use cards giving a description of the meter written along the top of the card, and below the movements of the meter are set forth, with dates against them, thus:

No. 123,456	Type N.	Volts 200.	Amps. 10.	K 1.	Testing K 20.
In from makers					20 . 4 . 04
Out to J. Smith, 99, East-street.....					22 . 4 . 04

Received from makers.	Date.
Sent to.....	,,
In from.....	,,

The tests made should be immediately entered in a day book, and with the aid of the date shown on the card it will not be difficult to find any desired test. It is advisable to change consumers' meters at intervals not exceeding two years. A convenient method of keeping up the proper rotation is to use a meter-changing card, ruled on one side, and giving particulars of consumer's name, address, district, pressure of supply, type, constant, size, and date fixed of the meter. This card should then be placed behind a guide card, showing the same month two years ahead.

Name: J. Smith. *Address:* 99, East-street.
District: 3. *Pressure:* 200.

Capacity.	Type.	Constant.	Notice sent.	Fixed by.	Date fixed.
10A	N	1	New consumer	Jones	22 . 4 . 04

Digitized by Google

The balancing of the three-wire low-tension network is in the charge of the meter superintendent, and to keep this correctly recorded cards are used, showing the consumer's name, address, demand, polarity, and time of extinguishing. For a two-wire installation with two service lines, a white card is used; for a two-wire installation with three service lines, a salmon-coloured card; and for a three-wire installation, two blue cards. A "totals" card is put at the beginning of each street or section of a street, and this indicates the state of the balance on any particular section at a glance. The card which is left on the consumer's premises is ruled in three columns for date, reading of meter, and inspector's initials. It is made to fold double, and on the outside are placed the consumer's name and address, the number and size of the meter, and its constant for units. There are also a few printed notices and instructions for consumers.

3. The books used in the meter department need not be many. For the use and direction of the workmen three books are needed. They are: (1) the work book, in which particulars of fuse replacing, special meter readings, disconnection, reconnections, etc., are entered; (2) the meter-changing book, in which particulars of all meter changes are recorded; and (3) the inspector's report book, in which workmen report any remarks made to them by consumers, any defects in meters or other apparatus, or any similar matter. The installations connected are entered in a day-book, known as "Watts Wired Book." This book merely shows the name and address of the consumer, the distance in miles from the station, the wiring contractor, the consuming devices connected or disconnected, and the date. For noting particulars of installations, the testing inspector carries a pocket-book with the necessary headings printed in it.

4. It is the duty of the meter department to attend to consumers' complaints of accounts. This is rather a delicate matter at times. Consumers often do not sufficiently appreciate the fact that a few foggy days during a winter quarter make a difference in the amount of their accounts. They then make complaints and the matter is looked into. If the meter is apparently correct the consumer is asked if he will agree to pay the expense of testing if found so, while the Corporation make no charge if the meter is found to be inaccurate. This is, however, a rule which it is often advisable to break through to conciliate consumers. It is also advisable to send up to see if the consumer cannot economise by re-arranging his installation, as in the case of the complaint of poor light mentioned in III. 3.

5. Consumers who use a large amount of power frequently apply for a reduction in the price per unit, and this may often be profitably given. The calculation involved is simple. Taking the total units during a year, divide by 365; the result is the units used per day. Dividing this by the maximum number of kilowatts demanded, the number of hours per day during which the demand is maintained is found. The price to be charged may then be worked out on any two rates, such as 7d. for the first hour and 1d. afterwards. This is, of course, the maximum demand system without the demand indicator.

6. The allocation of wages, etc., is done weekly. It is hardly the object of this paper to advise as to financial management, but it is well to have as few accounts open as possible. Most wages are covered by the four accounts—meters, capital and maintenance, and testing, capital and maintenance. Tools and instruments are charged in separate accounts. The wages of meter readers are charged to revenue, but the wages of men engaged on new work are charged to capital. This, however, as stated above, is not the business of this paper.

7. The purchase of meters is an important matter, but it is more important to see that good meters are bought when a purchase is made. Most makers are willing to go to the trouble of sending a sample meter for examination, and whenever the superintendent of a meter department or the manager of a supply undertaking comes across a meter with which he is not familiar, he should at once endeavour to obtain one for testing. Manufacturers will always send if the user undertakes to buy the instrument if satisfactory.

The staff of the Sheffield meter department consists of meter superintendent, testing inspector and boy, chief clerk, two junior clerks and office boy, foreman meter inspector, meter tester, four meter inspectors, relief man—a total of 14 individuals. Their duties are obvious and have already been referred to in the descriptions which have been given of their work. The system of interdepartmental working before referred to will now be described. It is worked from the general office by mans of the "Ticket Book." The operations in connection with this book are the following: The intending consumer signs the application form and the clerk in the office writes the first ticket, giving particulars of the application. This is sent to the meter department, and the polarity, voltage, and number of service lines to be installed, are decided, and the counterfoil is sent back to the office. At the same time a ticket is issued from the general office to the mains department, directing it to prepare plans, etc. The third ticket to be written is sent from the general office to the mains department, and contains instructions to lay the service as decided above. When the service is laid, the counterfoil is sent to the office, which then sends out instructions to the meter department to fix meters. This is done, and the counterfoil returned. When the contractor's test notice is in and the meters are fixed, instructions to test and connect are sent from the office to the meter department, and when the job is completed the final particulars of the service are sent to the drawing office. Additions are dealt with in a similar way, and thus the necessity of allowing the consumer's application to go out of the office is avoided. This system has been employed at Sheffield for nearly four years, and has been found satisfactory.

This paper has been written with the intention of setting forth clearly and intelligibly a method of running a meter department, which has been tried for a number of years, and has been found to have few defects. The importance of the work of a meter department is not always realised, and if this paper succeeds in causing it to be better understood and appreciated it will have fulfilled its object.

Discussion.

Mr. J. Christie, of Brighton, thanked the author for the valuable paper which he had read. The difference between the units generated and units sold in electricity supply systems was more than could be accounted for by the distribution losses. If this difference could be reduced, as he thought it could, the saving would more than repay the extra cost incurred in meter testing as recommended by the author. He did not believe in a Corporation inspecting consumers' wiring as this should be done by the fire office.

Mr. Dick, of the Reason Manufacturing Company, lamented the fact that there was not a good English treatise on electricity meters. The German and American books did not cover the range of English meters. If they could make 2 per cent more revenue due to more accurate metering it was equivalent to a 15 per cent. saving in the coal bill. In testing meters they should distinguish between the inherent accuracy and the apparent accuracy of the meter. It was no use reading a large number of figures when the accuracy of the last two or three was nil. He thought it was best to buy the most accurate meter and not the cheapest. He quoted an American expert to the effect that the errors averaged against the supply company, and that the possible saving would often more than convert a non-paying company into one earning a good dividend.

Mr. J. Venner made some remarks as to commutator meters, and promised the author a new type of prepayment meter to test shortly.

Mr. W. A. Chamen, of Glasgow, was much in favour of cyclometer dials for meters, but had not found makers very ready to supply them. As regarded staff, Mr. Cridge seemed to recommend two classes of employés, both of which fixed and inspected meters. Was this so? They in Glasgow had put off the introduction of the penny-in-the-slot type of meter. Experiments in the gas department had shown that these meters were often tampered with.

Mr. J. K. Brydges, of Eastbourne, had had quite as much trouble with the permanent magnets of the commutator type of meter as with the commutators. He described a testing battery he had set up of test-tube accumulators with lead wires as electrodes. It was a cheap and effective form, and quite light. He asked the author if it was not illegal to give special reductions to large consumers.

Mr. G. Wilkinson, of Harrogate, criticised the large staff required by the author to look after meters. In his own case one meter man and two lads did the work, with 1,300 meters out on circuit. He made a point of advising all consumers whose consumption was found to be very small as compared with previous quarters that their meters had stopped, and that they would be charged for a consumption based on previous years. This always brought a reply if the reduction was due to the consumer not using the light. They had recently had an inspector appointed by the Board of Trade at Harrogate after much agitation on the meter question. The testing of 120 meters, all of which had been complained of, showed that out of bills totalling £6,000, the total errors were as low as between £30 and £40.

Mr. Cridge, in reply, said he had found that the fire offices did not test insulation often, but preferred to rely on the Corporation tests. He had only got 12 commutator meters, and thought that the commutator troubles were

Digitized by Google

more than those due to demagnetisation of the permanent magnets. He had found makers most willing to use cyclometer dials for an extra charge of 1s. 6d. to 2s. per meter. This meter maker had also to do outside work, such as the fixing of meters, etc. There was no more illegality in special rates to large consumers than in the maximum demand system; both gave preferential treatment. The meter readers had always to test the starting up of the meter on one lamp when taking the records.

Polyphase Sub-Stations: Their Equipment and Working.

BY S. L. PEARCE, CHIEF ELECTRICAL ENGINEER, MANCHESTER.

Introduction.

The supply of electrical energy over very largely extended areas, either for traction or lighting purposes, or both, has necessitated the introduction of polyphase systems of generation, transmission at high voltages, and the distribution from corresponding sub-stations of low-voltage direct or polyphase currents. Again, the difficulty of securing convenient and suitable sites in the centre of the supply area has driven some municipalities to put down large generating stations on the outskirts of their towns, and in this case some system of high-pressure transmission and low-pressure distribution becomes a necessity. The sub-station and its equipment is, therefore, one of the most important factors in connection with such a system, and on its suitability success will largely depend. The author does not intend to put forward anything particularly original on this subject, but proposes to deal with the various types of sub-station equipments that have come chiefly within his own experience, and to consider some practical points that have arisen in connection with their working.

Considerations Determining Equipment.

There are several considerations which will determine the particular type of equipment to be employed, and it is desirable briefly to state these: (*a*) traction or lighting requirements; (*b*) frequency of the system; (*c*) two *v.* three phase. The first of these considerations is of great importance, as it will be seen hereafter that some equipments are more suitable for the ever-varying loads and overloads met with in traction work than for the steady lighting loads where a constant pressure is of prime importance. For "mixed" systems—*i.e.*, traction and lighting combined—it will be necessary to consider such equipments as will in a measure combine both the above points. The second consideration will depend almost entirely on the first. As the frequency of a system has such an important bearing on the capital cost, it is desirable wherever possible that this should be kept high, say from 40 to 50 cycles, otherwise the main generators, transformers, and motors will become much heavier, and therefore more expensive, and at this frequency "mixed" systems can be conveniently operated. The lowest frequency at which arc lighting can be done satisfactorily is about 42, and and incandescent lighting between 30 and 40. On the other hand, a low frequency of 25 is desirable for the operation of rotaries, as the difficulties of commutation and parallel running increase with the frequency. The third consideration—viz., the question of two-phase *v.* three-phase—will be decided on for reasons apart from those connected with the sub-station. The relative cost and efficiency of generating plant and transmission lines for two or three phase will have to be taken into account. It may fairly be stated that three-phase generators are cheaper to build and lighter than two-phase, whilst their efficiency is equally good, if not better. The transmission cables are simpler, as also are the switching devices. Theoretically, also, at any rate, a greater power can be transmitted in a three-phase system with a given weight of copper than on a two-phase system. As far as the machinery at the sub-station is concerned there is little to choose between two and three-phase where efficiencies and cost are concerned, as will be seen from Table I., which is taken from Mr. Field's paper on "Systems for Feeding Low-Tension Networks," read before the International Engineering Congress, Glasgow, 1901. Taking these various points into consideration there is little doubt that three-phase is to be preferred, as it is no more complicated than two-phase, has advantages in prime cost, gives a better over-all efficiency, and has been adopted in the majority of installations in this country. The author is aware, however, that there are one or two successful two-phase plants at work. In these cases two-phase has probably been adopted owing to a system of single-phase mains having previously existed. The change from single-phase to two-phase can be readily made, as has been done in the case of the Metropolitan Company, where two-phase motor-generators are used for that part of their system requiring direct current. The equipment to be considered in this paper will be of the three-phase type, with terminal voltages of from 5,000 to 10,000.

Converting Equipments.

(*a*) *Rotary Converters.* — The term "rotary converter" is intended to apply particularly to that type of machine in which the armature is provided with but one set of windings, the same winding serving to receive the incoming primary three-phase currents from the slip rings at one end and delivering the direct current on the secondary side from the commutator at the other end. The voltage on the alternating-current side between slip-rings is, therefore, a definite percentage of the direct-current voltage, being approximately 61 per cent. for three-phase working with three slip-rings, 70 per cent. for two-phase with four slip-rings, 35 per cent. for six-phase working with six slip-rings, and 50 per cent. for four-phase with four slip-rings. [These values are dependent on the pole width.] As rotaries must be operated at low-pressure, static transformers will be required to reduce the feeder pressure before applying to the slip-rings on the alternating-current side. The outstanding advantages to be obtained from the use of this class of converter are low prime cost, high efficiency, ability to stand overload limited only by the temperature rise, small floor space for a given output, and the high power factor which can be maintained over the system. On the other hand, there is a certain want of stability which manifests itself in sensitiveness to variations in the line voltage, causing difficulty in parallel running, and a tendency to hunt and get out of step. This want of stability is more noticeable in rotaries built with laminated steel poles than in those with solid pole pieces. The regulation also is not as flexible as in other systems, and switchgear and switching operations become somewhat complicated; but for purely traction schemes, their high efficiency, and ability to stand very considerable over-loads, are factors of great importance which more than outweigh the disadvantages named. Although the six-phase connection for rotaries is complicated, there is a considerable economy to be gained in the use of it—a fact which is being recognised in the latest installations in this country. Owing to the distributed nature of the tappings on the alternating-current side, the heating of the armature is more uniform, and there is consequently a considerable gain in the output, since this depends on the temperature rise. The step-down transformers may be connected up either "star" or "mesh." The advantage of the latter method lies in the fact that should one transformer be put out of circuit through any cause, the supply will not be interrupted; the remaining transformers will still maintain a three-phase supply to the converter, which can be run at its full load as long as the heating in the two remaining transformers does not become excessive. "Star" connected transformers are cheaper in first cost, since the pressure between the centre point of the star and the ends of either transformer is proportionately less than the line voltage. For lighting schemes with distribution on the three-wire or three-phase system, there is a distinct advantage to be gained by the "star" connection, since the centre point can be connected to the middle or neutral conductor for balancing purposes. It has been pointed out previously that rotaries should be operated at low frequencies of 25 to 30 cycles per second to attain the best results. This guarantees the more stable operation of the machines, and permits a wider range of compounding than is obtainable with higher frequencies. The author believes that the tendency in the future will be towards standardising periodicities of 25 and 50, as the latter, being an exact multiple of the former, enables the prime movers to be built on exactly similar lines, the only difference being in the number of poles. Where rotaries are being operated at 40 to 50 cycles, it would appear desirable to have connected on the same system a proportion of induction motors, which would tend to act as "electric dashpots" in the system, and thus help to make the rotary converters more stable than they would be in a system having nothing but rotories.

(*b*) *Synchronous Motor-Generators.*—This type of equipment

Table I.

Type of sub-station.	Cost.	Efficiency of equipment. Full load	¾-Load	½-Load	Total weight.
	£				Tons.
Three-phase rotary with transformers	A. 2,160	91	89·75	86·75	33
	B. 2,560	92	90·5	88	31

	B. 2,300	85	84	81	45

N.B.—A and B refer to different makers. All the above refer to 500-kw. converter equipment, operating at 25 cycles and 6,500 volts.

Digitized by Google

consists of a synchronous motor driving one or more generators, the whole constituting one complete and self-contained set. No intermediate transformers are necessary, as the line pressure is brought straight on to the terminals of the stator of the motor. It is usual to build the motors of the revolving field type, with the exciting current led up through slip rings to the field coils, either from an independent exciter mounted on to the end of the shaft from the generator terminals, from the low-tension lighting 'bus bars, or other means to be described later. The merits of this system in which higher frequencies can be employed are simplicity of operation, flexibility, high power factor in working, and the fact that the regulation of one direct-current side pressure is independent of the alternating-current voltage. As compared with rotaries, they are some 3 to 4 per cent. less efficient, and their ability to stand overloads is determined by the overload capacity of the generator. For lighting and "mixed" systems the synchronous motor-generator has much to commend it on the ground of stability, satisfactory parallel running, and ease of regulation.

(*c*) *Non-Synchronous Motor-Generators.*—This equipment differs from the former only in the employment of non-synchronous motors in place of synchronous motors, and is the simplest type of sub-station plant that could be devised. The high-pressure currents in this case also are led either through choking coils or direct to the motor, and the starting up is accomplished from the high-tension side. Consequently no complicated switchgear is required, and synchronising is obviated. As with synchronous equipments, the regulation on the direct-current side is independent of the alternating current. The great drawback to non-synchrous motors is the comparatively low power factor at which they work. For mechanical reasons the width of the air-gap in induction motors is considerable, more particularly with small units, and it is advisable to watch this closely with a view to keeping it equal at top and bottom of the rotors. In order to avoid heavy lagging currents on the system, the motors should be run well up to their full load. Lagging currents not only waste energy, but pressure regulation becomes exceedingly difficult owing to their demagnetising effects. It is for these reasons that the use of small non-synchronous motor-generators alone is not to be recommended, but a combination of the types (*b*) and (*c*) can be used with good results. In every sub-station means must be provided for starting up from the alternating-current side in the event of low-tension direct current not being available. For this purpose the motor-generator with an induction motor is specially useful owing to the rapidity with which it can be started to enable a supply of direct current to be obtained for starting up the synchronous sets. If the latter be run with their fields "stiffened" or slightly over-excited, the heavy lagging currents of the induction motor may in some measure be compensated for, and the power factor of the system thereby improved. A modification of the ordinary induction motor-generator has recently been brought forward by one firm in this country under the name of "motor-converter." This combination consists of a direct-current generator coupled to an induction motor, the two machines being electrically as well as mechanically interconnected. High-tension currents at 50 periods circulate in the stator windings of the induction motor. Owing to the back E.M.F. of the direct-current machine the speed of the rotor, however, corresponds to half synchronism only. Currents are therefore generated in the rotor windings at a periodicity of 25, and these currents pass into the direct-current armature by suitable cross-connections, and are there commutated. Theoretically half the power of the combination is transmitted through the shaft, and the remaining half through the electrical cross-connections. In the first case, the direct-current machine acts as a generator; in the latter case, the motor acts as a transformer, and the direct-current machine as a generator. To a certain extent, therefore, this machine appears to combine the advantages possessed by both motor-generators and rotary converters, and the practical results obtained therefrom will be of considerable interest. The following table shows the relative cost, efficiency, floor space, and power factor of various sizes of the three classes of equipment, (*a*), (*b*), and (*c*):

VOLTAGE 6,500. FREQUENCY 50.

	Asynchronous motor-generators.	Synchronous motor-generators.	Rotaries.
Output	220 kw.	220 kw.	220 kw.
Costs	£6·1 per kw.	£5·5 per kw.	£3·8 per kw.
Efficiency (full load)	86 per cent.	89 per cent.	92 per cent.
Floor space	12ft. 3in. × 8ft. 5in.	12ft. 3in. × 8ft. 5in.	7ft. × 7ft.
Power factor (full load)	Approx. 92 per cent.	Approx. Unity.	Approx. Unity.

Fig. 1 comprises three curves showing the approximate relative cost of three types of sub-station equipment.

(*d*) *Static Transformers.*—The distribution of polyphase currents at low pressure is undoubtedly coming to the front. There are already in this country instances of new and successful public lighting schemes on this system, and a considerable demand is springing up in various towns for a supply of three-phase current to large works, more particularly in engineering and shipbuilding districts. A sub-station of this type has recently been put down in Manchester for the supply of three-phase current at 200 volts to some extensive locomotive works, where it is expected that the ultimate demand will be approximately 700 kw. It seems reasonable to suppose that the present recognised systems of converting alternating current to direct current will in time be superseded by one embodying direct transformation from high to low pressure. When one considers the increased capital involved in respect of plant and buildings for sub-stations equipped with rotaries or motor generators, the increased labour costs for running and maintenance, and the moderate all-day efficiencies obtained, it would appear that the polyphase system of distribution for mixed "lighting and power schemes" has much to recommend it. The three-phase motor is proving eminently satisfactory where speed regulation is not a prime essential, and the difficulties even in this respect are not insuperable. Three types of transformers have been employed in the equipment of sub-stations for obtaining efficient cooling: (*a*) oil-cooled; (*b*) forced draught ventilation; (*c*) natural draught ventilation. The transformation of polyphase currents can be, and more frequently is, carried out by the use of three single-phase transformers, which may be connected up either "mesh" or "star" fashion. The advantage of using three-phase transformers is a saving in copper and iron, resulting in a lower first cost; further, their common magnetic circuit tends to reduce any variation in the pressure between the phases, and for this reason they are preferable for use on lighting

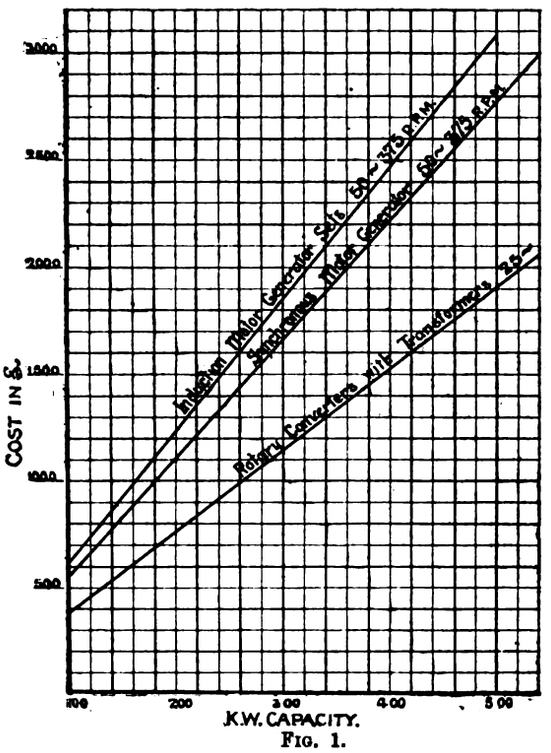

FIG. 1.

circuits. The great advantage in using the single transformer type is that breakdown risks are minimised, and a smaller amount of spare plant is required. These points largely counterbalance the advantages attendant on the use of three-phase transformers. Transformer units should be few in number, and of as large an output as possible, since, although any gain in efficiency by the employment of large units may be inappreciable, simplicity in the arrangement of the sub-station and the reduction of the switchgear required to a minimum are important factors. Either of the two first types (*a*) and (*b*) will give good results, particularly if in the former proper means are taken with the larger units for securing the cooling of the oil by circulating cold water through it, or *vice versâ*. The second method has been more generally used in the author's experience. This type of transformer constructed with sub-divided coils not only keeps the transformer cool by allowing the forced air to circulate, but renders it more easy to insulate for voltages up to 10,000 with perfect safety. Forced-draught cooling involves the use of a blower, which is usually driven by a small induction motor operating at low pressure. Such types of transformers are capable of giving very large outputs for their weights and high efficiencies. There is always the risk of breakdown of the induction motor to be reckoned with, a state of affairs which usually ends in the particular bank of transformers being put speedily out of commission. The third type has much to commend it, as without a doubt air blasts, oil, or any other cooling devices are somewhat open to objection. Given large radiating surfaces inside and out, combined with ample ventilating spaces through which currents of fresh air can continually pass, this

Digitized by Google

type should give as good results as either of the former. The following table gives the comparative cost for the various types of a 250-kw. equipment, working at 5,500 volts and 50 periods:

	Three-phase transformers. £ per kw.	Three single-phase transformers. £ per kw.
1. Oil cooled	·8	1·4
2. Cooled by air blast	·78	1·17
3. Natural cooled	·9	1·5

SWITCHGEAR.

The author proposes to deal briefly with this part of the equipment of a sub-station, which has been very truly named the "nerve centre of the system," and upon the high-tension side of which the greatest care and thought should be expended both as to the design and general arrangement, so as to ensure safety and reliability.

Position of Boards.—It will be found convenient to place the high and low tension boards on different galleries, either opposite to or at right angles to one another, but on the same level, with easy means of communication between the two. This arrangement, besides having the advantage of separating the high-tension and low-tension gear, will facilitate the wiring up of the station, and avoid any dangerous crossings of the cables.

Type of High-Tension Board.—Much has been written of this somewhat thorny subject, and the matter is still to a great extent *sub judice*. Three distinct types, however, have come within the author's experience—viz., the flat-board, the multi-frame, and the cellular or compartment board. The former, with its exposed switches, fuses, and wiring, etc., mounted sometimes dangerously low down, and small space provided at the back is quite unsuitable for high pressures, and is rarely seen now in later high-tension sub-stations. Several modifications of this type, however, are in use, such modifications consisting in raising of the height of the high-tension 'bus bars and partially covering them in, live fittings of any description being exposed only at the back and top, the front being absolutely free from any high-tension work, and the instruments mounted at the front being worked off transformers. Examples of high-tension switchboards on these lines have been installed at the Central London sub-stations, and are doing good service. The "multi-frame" type of board may be said to represent very largely the continental practice, and consists of practically two or more distinct frameworks, the first carrying the marble front on which are mounted the switch handles and instruments worked off transformers. The second framework may be behind or above the former, thus forming a second gallery. This latter carries all the high-tension work. Ample passage ways are provided all round, and in addition all high-tension parts are enclosed in caging of iron meshing, with suitable doors which can be locked as required. This type has the disadvantage of taking up considerable floor space, but the possibility of attendants getting round to the high-tension portions at the back is not great, and the boards are readily accessible for cleaning and repairs when required. Next to safety should come efficiency and reliability, and on these points the multi-frame board gives excellent results. The "cellular and backless" type of board in one of its particular forms is well known in this country, and has been most extensively used in single-phase systems. Its adaptation for two and three phase working will be watched with considerable interest, especially as in some schemes it has come into direct comparison with the multi-frame type. The whole arrangement of this type of board is too severely compact for the higher pressures and powers, and repairs are not easily effected when required, but the saving in floor space is considerable, which is a consideration when sub-station sites are restricted in this respect. Other types are generally modifications, combinations, or extensions in some form or other of those named. In some cases the switchgear is sub-divided into sections, occupying different galleries, or forming groups on the same gallery. In other cases all the high-tension gear is remotely controlled, operated by hand direct or auxiliary relay apparatus, either electrical or pneumatic.

Arrangement of 'Bus Bars.—The arrangement of the 'bus bars is the first question to decide when the type of board has been settled. Simplicity, as far as it is compatible with reliability of supply, is essential. With a mixed system the author considers that this is fairly obtained by using one set of 'bus bars for lighting and another set for traction, every feeder and every machine being provided with "change-over" or "selector" switches, so that they can be connected up to either set of 'bus bars. In effect a set of duplicate 'bus bars is thereby provided. Means can also be provided if desired for coupling together the two sets of bars in the sub-station, but where it is the rigid practice to keep the traction and lighting 'bus bars separate, it may be desirable that coupling switches should be provided at the generating station only. In the case of a lighting system only, it is still advisable as a stand-by and as a means of isolating any generator on to any feeder, that a duplicate set of 'bus bars should be provided. The use of a second 'bus bar has always been found invaluable in the testing of any faulty feeder or machine, as it permits of this being done during the hours of ordinary supply. Such an arrangement of duplicate bars is, in the author's opinion, preferable to the so-called ring systems with disconnecting links. For these reasons the extra capital cost involved will be well repaid by the increased reliability and efficiency of working. The question of "fusing" or not fusing is one that is still being much debated. If fuses be decided on, then two conditions may be laid down as essential: (1) they must open circuit cleanly and without enabling a rise in potential to take place; (2) they should be situated on a gallery or in a basement alone, in short they should be severely isolated from the rest of the high-tension gear, where in the event of failure of action the damage is confined to a comparatively small area. They should also be in duplicate. It may safely be stated that excessive rises in pressure on interrupting the circuit are not experienced with oil-break fuses, but whether this or the ordinary type be adopted, the employment of spark gaps in addition on the system is to be recommended, as the additional expense is trifling. Someone has truly said that fuses are very good things to do without, and from the author's recent experience he is inclined to the conclusion that fuses are not to be relied on in extra high-pressure work, and that the substitution of an "overload" oil-break automatic switch with time limit and mechanical or electrical control attachment will give the best results. Such an arrangement should be fitted to each high-tension machine in the sub-station, the high-tension feeder ends being connected straight on to the 'bus bars, and controlled by automatic oil-circuit breakers of the overload type at the power-house end only. In some cases reverse current circuit breakers have been fitted on the feeders at the sub-station ends to ensure continuity of supply in the event of a short-circuit occuring on any one feeder. For the protection of high-tension overload circuit breakers in the event of a feeder breaking down, and to ensure their reliable working, the arrangement shown in Fig. 2 has been adopted in one or

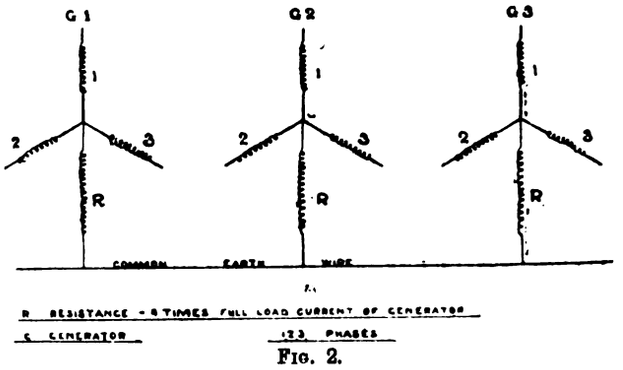

FIG. 2.

two systems in America, and is to be used on the Metropolitan District Railway, London. Between the centre point of the star winding of the main generator or the sub-station converters and the earth bar, a resistance is inserted which will only carry four times the full load current of the machine. As three-core feeder cables rarely break down between cores, but generally to earth, the amount of current passing can only with this arrangement equal four times the full load current of the generator.

Synchronising.—The tendency appears nowadays to be in the direction of synchronising at the line voltage. There appears to be little to recommend this, and it certainly is desirable on the grounds of safety to work off low-tension synchronising 'bus bars.

Cable-Charging Gear.—The question of the advisability of providing cable-charging apparatus is another moot point. The author believes that in the majority of case there is probably no need for this provision, and he would instance the Central London and Glasgow equipments with high-tension feeders some four to five miles in length. The American practice is decidedly opposed to the instalment of this apparatus, and there is hardly a power station in the States to be found so equipped. It would be out of place somewhat to consider the *pros* and *cons.* of the question in this paper, or of the various types used—viz., (1) separate motor-generator forming the cable charger; (2) water resistance; (3) the "Partridge" arrangement, involving the employment of a three-phase transformer, the primaries being connected in series with the three-core cables, and the secondaries connected up to a non-inductive resistance.

High-tension switchgear appears to be passing through a transition stage, designs seem to be changing almost every year, and nothing can be called standardised in this direction. Probably the design of the future will be one that combines the cellular or compartmental arrangement with remote control.

EXAMPLES OF ROTARY EQUIPMENT.

Fig. 3 shows the general arrangement of one of the rotary sub-stations in connection with the electrical equipment of the North-Eastern Railway. The size of rotaries employed is 800 kw. with three-phase connections. All the high-tension gear is placed down one side of the station, and the low-tension

Digitized by Google

gear on the opposite side, with the rotaries and their accompanying transformers between. The incoming high-pressure feeders are fitted with spark-gaps, provision being made by means of isolating switches to allow of their inspection while the feeder is alive. The feeder switches are of the oil type, capable of breaking the maximum current of the station, and electrically operated from the low-tension board. In connection with these switches are reverse current relays, which automatically open the switch should the current reverse. The main high-tension 'bus bars are placed on the top gallery and enclosed in fireproof cubicles—the main switches being situated

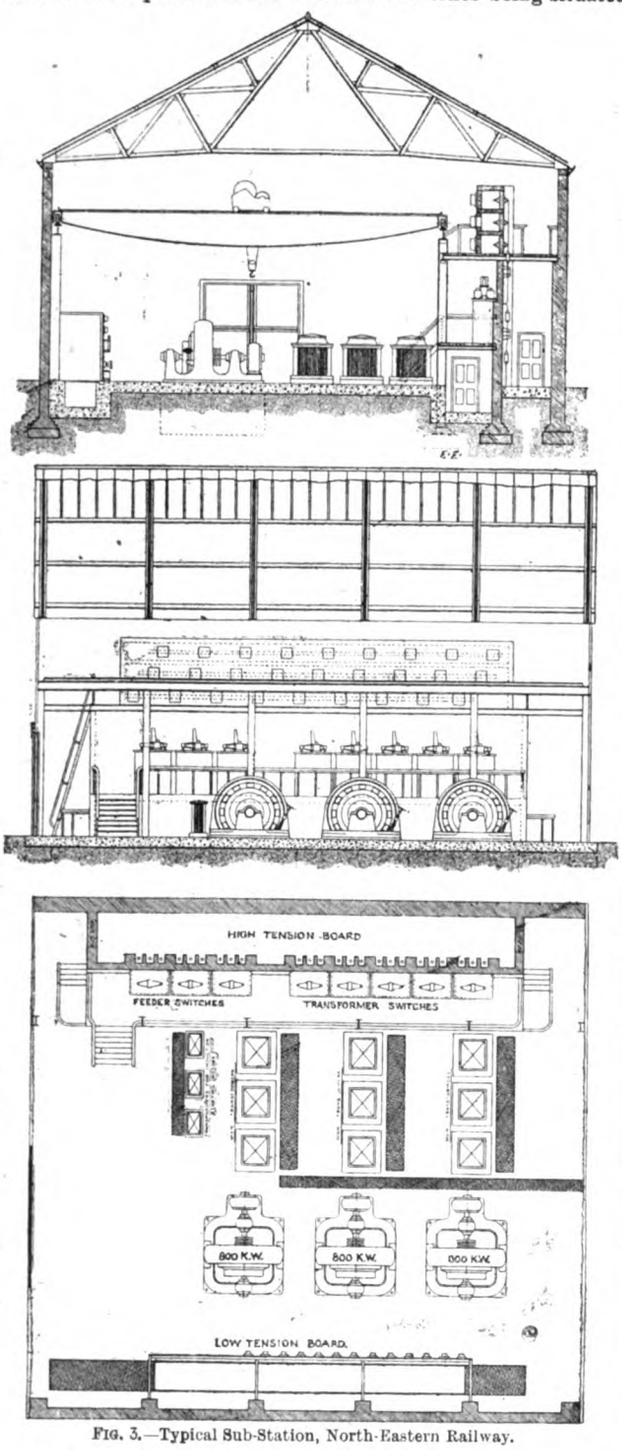

FIG. 3.—Typical Sub-Station, North-Eastern Railway.

on the intermediate gallery—the fireproof wall supporting the high-tension gear being built of cement blocks, with partitions between each phase and each circuit. Electrically-operated switches are placed in the circuit between the high-tension 'bus bars and the primaries of the transformers, fitted with time-limit overload cut-outs, the secondaries being connected straight on to the three slip-rings of rotaries. Provision is made for all high-tension circuit breakers to be inspected and cleaned with safety by means of isolating switches. The main transformers are of 280 kw. each, with a voltage ratio of 5,500/360 working at a frequency of 40. They are oil insulated of the self-cooling type, and are connected up in "delta." The rotaries are started up by means of induction motors mounted on an extension of the armature shaft, separate step-down tranformers being provided for the supply to these motors. The machines have an efficiency of 93·44 at three-quarter load to 93·94 at 1½ times full load. The low-tension switchboard, besides containing the ordinary panels for operating the direct-current side of the rotaries, comprises the panels for the operation of the oil-switches on the high-tension feeders and transformers.

(To be continued.)

PHYSICAL SOCIETY.

At the meeting of this society on June 24, Dr. R. T. Glazebrook, F.R.S., president, in the chair,

A paper on **"Chemical Dissociation and Electrical Conductivity,"** by **A. E. Garrett** and **Dr. R. S. Willows,** was read by Dr. Willows. It has been shown by Beattie (*Phil. Mag.*, 1899) that a mixture of salt and iodine, when placed on a zinc plate and heated, gives rise to electrical conductivity, although separately no such effect is produced. This is shown to be due to the formation of zinc iodide. Following on this the electrical conductivity produced by heating various salts is investigated under different conditions of temperature and electric field. A large excess of positive electricity is found in nearly every case.

Mr. Skinner expressed his interest in the paper, and pointed out that the chief leak did not begin until the iodine was completely vapourised. He asked if the ions were produced in the mixture or in the gas. Had the authors tried the effect of screening the mixture from the electroscope?

Dr. C. Chree remarked on the fact that the authors employed formulæ of the type $I = a t^n$, t representing absolute temperature under circumstances in which n was a large positive number, in one case as big as 100. To fit such a formula I must be practically either infinitely small or infinitely large, except over a very limited range of temperature. He should like some further details as to the method of arriving at formulæ of a type so remarkable physically, and as to the range of temperature wherein they were supposed to hold.

Dr. Willows, replying to Mr. Skinner, said that the effect was still produced when the mixture was covered with a metal plate, but they had not tried screening with mica. In reply to Dr. Chree, he said that their formulæ held over a range of 100deg. C., and that Dr. H. A. Wilson had arrived at a similar formula which applied over a range from 200deg. C. to 1,000deg. C.

A paper on **"The Magnetisation of Iron in Bulk"** was read by **Dr. W. M. Thornton.** The paper is in three sections. The first describes a method of measuring large quantities of magnetism by the use of an exploring coil placed around the core and an exciting coil in series with a recording milli-voltmeter. This was applied to determine the complete loops of magnetisation for two rings of cast steel and cast iron weighing respectively 3cwt. and 6cwt. The results were checked by a quantometer. The second section deals with the curves of rise of magnetising currents, when the core is solid and when laminated, as affected by the reaction of the core currents, and also by the change of permeability during magnetisation. A second simple method is given of measuring large quantities of magnetism in circuits having a large time constant, suitable for testing dynamo-electric machines. From two curves of rise, with the current in one reversed, expressions are given for finding the total induction in the core and its ratio to the residual magnetism. In the last section an example is given of the sudden dip in the curve of rise observed only with large cores. The growth of current in a coil surrounding a solid circular core is calculated by Heaviside's formula, assuming constant permeability. No dip is found in the calculated curve, and it is therefore caused by a brief magnetic impulse which corresponds to the slip of the molecules at saturation seen in Ewing's model of the magnetisation of iron. Photographs are given showing the direction of flow of eddy currents in cores of rectangular section of proportions 1 : 1, 1·5 : 1, and 2 : 1.

Prof. S. P. Thompson expressed his interest in the paper, and referring to the curves showing the rise of the magnetising current, said he thought the explanation given by the author was not the only possible one. He was not inclined to think that the effect was due to internal eddy currents in the core. The fact that the growth of the magnetisation current was irregular was well exhibited in separately excited dynamos with large field magnets, where the effect could be easily seen in the movements of the ampere-meter needle. In the author's curves showing the rise of the quantity of magnetism in a circuit with the current, first with the current direct and then with it reversed, he pointed out that a difference would be expected because the core would not be in the same magnetic condition at the beginning of the two experiments.

Mr. W. H. Pretty said that the question of magnetisation tests of iron and steel in bulk was a very important one. The curves shown by the author suggested the possibility of detecting cavities in steel castings, as such castings would doubtless give curves differing from those representing a truly solid block of the same material cast at the same time and subjected to the same after-treatment. It would be interesting to have a series of tests on the same block of steel, say, in which each process in the manufacture is represented—*i.e.*, as cast after annealing, and after the surface-scale or skin has been removed to various depths; also after the block has been cut up into slabs or laminæ and put together again. Referring to the dip in the curves of rise of magnetisation observed with large cores, Mr. Pretty said it was not unlikely due to internal mechanical stress and the accompanying strain, and that as it became possible to obtain steel more and more homogeneous such internal molecular changes would become more apparent.

Dr. Thornton, in reply to Mr. Pretty, said that he was now experimenting upon the effect of cutting up a large core into laminæ and then building up the core again.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

TRAMWAY ACCOUNTS.

Two sets of accounts relating to tramway matters have been recently issued, each of which is deserving of more than a passing notice, but we shall for the present confine our attention to one. The London County Council give the accounts for the year ended March 31, 1904, which shows a net capital expenditure in respect of the whole of the southern tramways of £2,124,228, of which £140,714 has been repaid out of revenue, leaving an outstanding debt of £1,983,514. The tramways include those worked electrically, with cables, and by horse traction. The detailed receipts and expenditure, unfortunately, give figures which are lump sums, and cannot, therefore, be read with any great amount of certainty. However, we give them as given in the report:

	Electric and cable.	Horse and cable.	Total.
Total receipts	£226,535 15 7	£309,703 11 11	£536,239 7 6
Working expenses	147,658 4 10	294,128 2 1	441,786 6 11
Gross revenue	78,877 10 9	15,575 9 10	94,453 0 7

The report remarks: "We wish to draw particular attention to these figures as showing the comparative receipts and expenses from tramways worked by electrical as against animal power, especially where the fact is taken into account that the total capital expenditure is about the same in each case." It would be much better if such utterly useless and misleading remarks were not made. They render such reports ridiculous, and tend to bring about the oft-repeated criticism that committees of the kind are incompetent and ignorant bodies. No useful comparison can be made from lump sums of the kind given. The whole of the conditions must be known and weighed before comparisons can be made. We must say we emphatically condemn the sentence quoted. It probably is the case that the percentage of working expenses to receipts is greater in the one case than in the other, and in favour of electricity, as has been proved in many instances, but these figures do not necessarily show it. The further figures given in the report do not help us, as they are not detailed. To really institute a comparison we must have not a combination of electric and cable, or horse and cable, but have electric, cable, and horse separately, the mileage receipts of each, and the working expenses per mile on each. No doubt such details are difficult or impossible to obtain; then why talk about comparisons. But we have said more upon this point than we intended. It is interesting to know that 133,139,085 passengers were carried during the year, an excess of 23,523,589 over the previous year, and that the car miles run was 11,536,534, an increase of 1,425,594 over 1902-3. It will be seen that the gross revenue balance is £94,453. The debt charges amount to £100,536, thus leaving a deficit of £8,283. We agree that this state of affairs cannot be regarded as unsatisfactory. The estimated deficit was £15,000. It must be remembered that the system has been in a transition state; hence the receipts will have been considerably diminished, and it is only just to admit that under normal working the deficit would have been changed into a very favourable surplus. Besides the lesser receipts there must necessarily be greater working expenses during temporary arrangements, so that on the whole as a business concern the management must be congratulated. The northern lines, being leased to a company, are not working under similar conditions to the southern lines, and the rent received from this source being brought into the totals gives a surplus revenue carried to appropriation account of £27,657. Roughly speaking, the foregoing gives the result of the year's working. Just a few words upon a subject to which it is well known we have given much thought. Even were the Council to proceed upon

Digitized by Google

the lines of the past year, it will be seen that quite early the balance must be on the right side, and that the reduction of debt charges due to reduction of debt really will play a most important part in all undertakings wherein a compulsory reduction of the kind goes on.

RHYMES FROM THE OFFICE.

BY PABLO.

No. 1.—Overtime.*

[* For many years past it has been the custom of a certain electrical engineering firm to furnish "special" teas for draughtsmen and clerks when, owing to stress of work, overtime has been necessary. For some reason, economic or otherwise, a notice was recently posted to the effect that "teas *a la carte*" would be discontinued, but that a "good plain meal" would be provided for men working over. This called forth protests in various forms, one being the set of verses here reproduced. It is pleasing to add that the old order of things has been restored.—P.]

When your neighbour leaves at five—
As he ought—
Consolation please derive
From the thought
That you're staying without fee,
Not for filthy £ s. d.,
That you do it all for glory—
And the tea.

Though lungs cry out for air,
Fresh and free,
And the day be clear and fair,
Heed not the plea.
Could you ramble in the wood,
When you'd left (as if you could !),
Left the glory and the tea,
Plain and good ?

Do you think of eyes of brown—
Or, may be, blue ?
Can you see the gathering frown,
Through lack of you ?
Could you choose a better part
Than the breaking of a heart,
Just for glory and a tea,
NOT *a la carte* ?

EARTHING ARRANGEMENTS AND LEAKAGE INDICATING DEVICES.

BY A. S. C.

The writer does not propose to consider broadly the question of earthing supply systems, but rather to present the everyday practice, more particularly in connection with three-wire distribution systems. It has been urged by some engineers that the middle wire of a three-wire system should be earthed throughout its entire length, or at a number of points on the network. The practice in England, however is to earth the middle wire at one point only, generally at the central station, or distributing sub-station. In almost all cases a switch or fuse is placed in the earth-wire connecting the middle wire to an efficient earth, and a recording ammeter should also be placed in the circuit. A very usual method is to place a light fuse or automatic switch in the earth-wire and to connect a fairly high resistance across the terminals of the fuse or automatic, so that when an excess current, due to a leakage from one of the outers, blows the fuse or opens the automatic, the resistance is put in circuit, and the middle wire is not disconnected entirely from earth. Some indicating device, such as a bell or lamp connected across the terminals of the fuse or automatic, is generally used to draw attention to the earth current passing, and steps should at once be taken to localise and remove the fault.

A very good arrangement which the writer has had in use on more than one three-wire system, and which has been found very useful in localising faults, etc., is described below. A small earthing bar is arranged so that it can be connected to the positive, negative, or middle-wire 'bus bar by means of a plug or three-way switch. The earth-wire is taken from this bar through an ammeter and an adjustable resistance to earth. In the ordinary way this bar is not connected to the 'bus bars, but is only used when a leakage occurs. The middle wire is kept at earth's potential by means of the leakage indicating arrangement, which consists of four lamps connected in series across the outers, with the middle point earthed through a switch, and with a switch in each of the outers. So long as the system is free from "earths" the lamps burn half bright, and on opening either of the outer switches the lamps go out. Opening the middle switch which connects the lamps to earth should make no difference. A leakage occurring on either outer at once lowers the potential of that outer to earth, which fact is indicated by the two lamps on the side on which the leakage is, burning dull or going right out according to the amount of leakage, and the other two lamps becoming brighter to the same extent. It will be seen that a very slight leakage current will be sufficient to cause a noticeable difference in the brilliancy of the indicator lamps. If the leakage current is sufficient to light an 8-c.p. or 16-c.p. lamp, the indicator lamps on the opposite side of the system burn brightly. An "earth" occurring on the middle wire will make no difference in the appearance of the indicator lamps; but when one or other of the outer switches is opened, only the two lamps on that side will go out instead of all the lamps, as is the case when the system is free from "earths." The leakage current, however small, returning by way of earth is sufficient to light the lamps on the side left switched on. By this arrangement an "earth" on either of the outer conductors is at once indicated, and any leakage on the middle wire can be ascertained by opening one of the outer switches. So long as all the switches are in the middle wire of the system is kept at earth's potential. As soon as an "earth" is indicated on one of the outers, the earthing bar referred to before should be connected to earth through the resistance, which can be gradually cut out if the current is not too great.

If the fault is on some consumer's wiring, it is probable that the blowing of his fuses will result from "earthing" the middle wire, and the system will be restored to its normal state. If, however, the fault cannot be removed in this way, it is probable that it is on the mains, and steps should be taken to locate the trouble. A middle-wire "earth" is not of such importance; but in the writer's opinion all faults, however small, should be at once dealt with, and it is by no means such a difficult matter to keep a system absolutely free from "earths" as some engineers maintain. If an "earth" is indicated on the middle wire, the earthing bar should be connected to one or other of the outer 'bus bars, and the same process gone through as before. In the latter case, however, it is not advisable to keep the outer earthed for any length of time.

Unless the trouble is on the mains, it is more than likely that the momentary earthing of the outer will be sufficient to blow the fuses on the faulty wiring and so remove the "earth." This earthing of the outers need not be done at times of heavy load. A little thought and discretion must be used in the matter. If the fault is on some consumer's premises, it is probable that it will occur at about the same time each day, and an attempt can be made to blow the consumer's fuses as soon as the fault is indicated. It is better to put a consumer to occasional inconvenience in this way than to allow faults to go on developing all over the system on the middle wire, as there is sure to come a time when one of the outers becomes earthed, and then *all* the consumers who have faults on the middle wire of their installations will have their fuses blown at the same time. By having the middle wire earthed in many places, it also makes it most difficult to locate faults on the outers of the system.

The arrangement of earth lamps above described can be adapted to suit a five-wire system by connecting two lamps across each circuit, the middle point being put to earth through a switch as before. Of course, if desired, one lamp made for twice the supply voltage may be used in place of the two lamps in series, but necessitates keeping lamps specially for the purpose, whereas if two lamps are put in series on each circuit, lamps for the ordinary supply voltage can be used.

For a two-wire system earth lamps are not required, but

Digitized by Google

the same form of earthing resistance with adjustable resistance may be used. The negative of the system should be kept earthed. But the positive should be earthed two or three times in the course of the day, so that any faults developing on the negative may be detected.

WIRELESS TELEGRAPHY.

BY R. G. BLAINE, M.E., A.M.I.C.E., ETC.

(Continued from page 20.)

GERMAN SYSTEMS.

The Arco-Slaby System.—This system, which is in successful use not only in Germany, but in various other countries, is the product of Prof. Slaby—who was present at some of Mr. Marconi's earlier experiments in England—and his assistant, Count Arco. Many of the ships of the German navy and German mercantile marine are equipped with the apparatus of these inventors, and over 50 new stations on this system have been installed during the one year. The various arrangements described by Prof. Slaby cannot be fully discussed here, but the principal features of the receiving and transmitting circuits will be given.

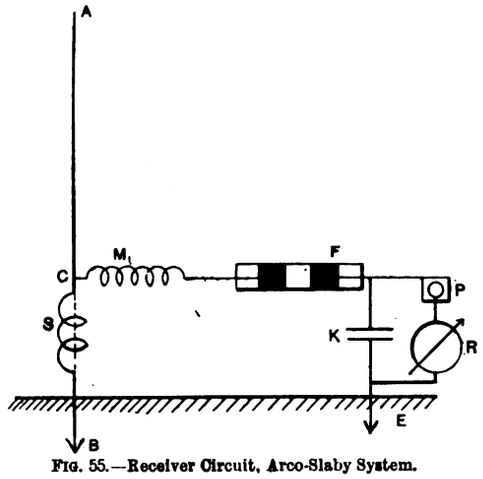

FIG. 55.—Receiver Circuit, Arco-Slaby System.

Fig. 55 shows one form of the receiving circuit, in which A is the aerial, M a coil "of special form and winding, producing at the coherer, F, a tension loop whose amplitude is considerably larger than at A." This coil, M, is called by Prof. Slaby a tension multiplier. Probably the reason for its use is the fact that at the top of an aerial the pressure is greatest (as shown in Fig. 3, p. 291), and hence the coherer ought to be placed there. This is, however,

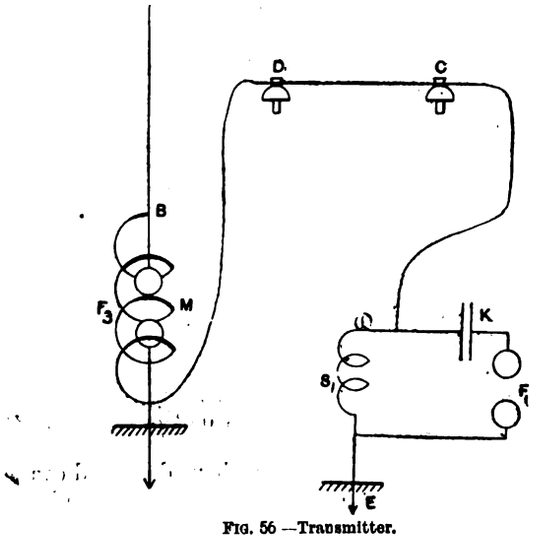

FIG. 56.—Transmitter.

not convenient, and Mr. Marconi got over the difficulty by introducing the transformer or "jigger" (nautical term for "hoister," used here because it hoists or raises the potential) at the foot of the aerial where the pressure is least, but the current greatest. Prof. Slaby by stretching a wire horizontally from the base of the aerial and making this wire of the same length (or inductance) as the aerial, gets a similar arrangement of pressure as in the aerial, and is thus able to place his coherer at a point corresponding to the top of the aerial. It is not necessary that this wire should be all stretched out straight, some of it may be in the form of a coil, and this coil is probably that to which Prof. Slaby refers in the passage quoted above. K is the condenser inserted parallel to the battery, P, of the relay, R. The capacity of K is about 100 times that of the coherer. Other arrangements are possible, for instance, in some cases two coils like M are employed, the coherer being connected to a point on the wire between them.

One form of the transmitting circuit, as used on warships, is shown diagrammatically in Fig. 56. The exciting circuit is earthed at E, and contains the variable self-induction, S_1, the condenser, K, the spark-gaps, F_1, and the insulated connecting wire, C D. In a watertight chamber on the deck is placed the multiplier, M, complete with spark-gap, F_3, and transmitting aerial, B. In the insulated wire, C D, there is, therefore, only the potential of the 15mm. spark-gap, F_1. In the aerial this is increased by the multiplier and spark-gap, F_3, to that of 150mm. or 200mm.

A complete station outfit for low-tension work is shown in Fig. 57, having the inductor (shown high upon the wall),

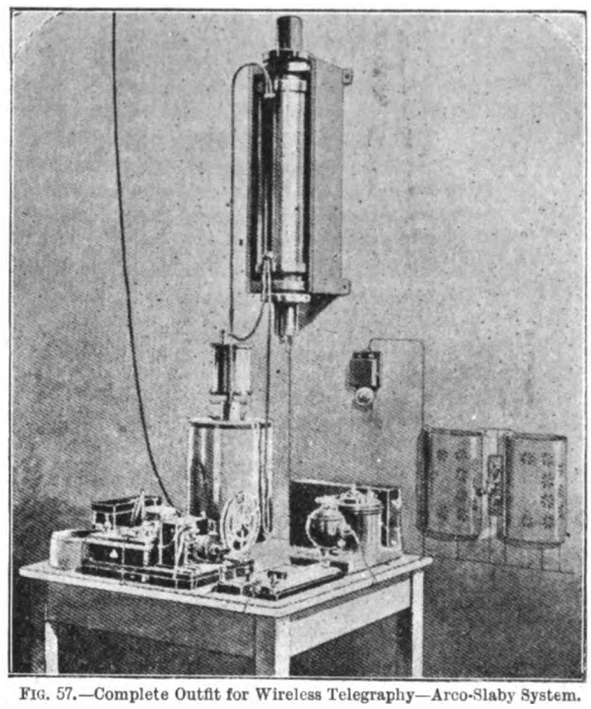

FIG. 57.—Complete Outfit for Wireless Telegraphy—Arco-Slaby System.

the primary condenser, turbine interruptor, Morse instrument, three-step regulating resistance, and lightning arrester. None of these call for special remark, except the mercury turbine interruptor (seen to the right on the table), which consists of a small turbine driven as a centrifugal pump by an electric motor. It squirts mercury through a small opening, two square millimetres in area, in a horizontal plane. A metal segment ring is placed on the turbine shaft, and the mercury strikes against this ring during a part of every revolution. The mercury is connected with one pole of the current supply and the segment ring with the other; the circuit is by this means opened and closed automatically with any desired frequency, which may be varied by varying the speed of the turbine. The turbine casing is filled with alcohol, to quickly extinguish the sparks caused by the break of circuit. For use on board ship the turbine is mounted on trunnions, so as always to remain with its axis vertical. This interruptor works very satisfactorily, but the use of several pounds of mercury is somewhat of a disadvantage, and to get over this difficulty another form has been devised, in which a disc provided with copper segments runs under carbon brushes, being driven by a motor, the variation of the speed of which gives the required variation of interruption.

For large electrical outputs the Grisson rotary converter is employed. This gives a true alternating-current instead

Digitized by Google

of the interrupted direct-current, due to the turbine interruptor. It is shown in Fig. 58. P is the inductor, which has besides its two main terminals, P_1 and P_2, a third terminal, P_3, which is connected as shown. Direct-current is sent into coil P_1, P_3, and is kept on till it reaches a maximum. When this is reached the current is passed through the circuit of a second coil, P_2, P_3. The coils have a common iron core, which they magnetise in an opposite

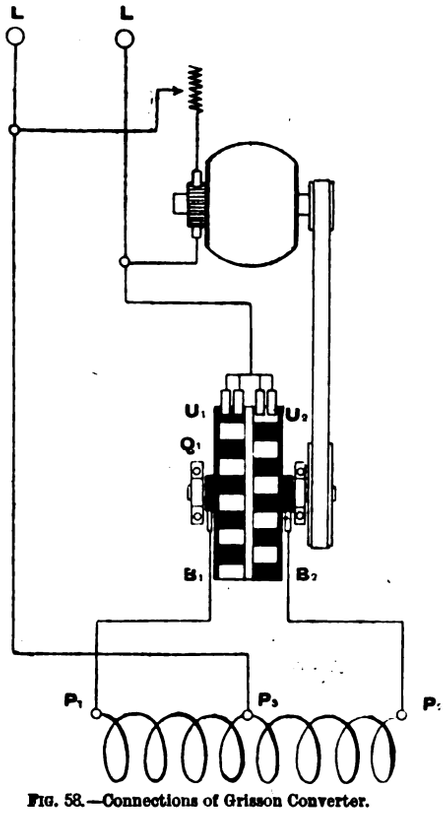

FIG. 58.—Connections of Grisson Converter.

sense, so that when the current is sent through P_2 P_3 a back E.M.F. is induced in the first coil, P_1 P_3, reducing the current flowing in it nearly to zero. At this moment the first circuit is interrupted, and the current in P_2 P_3 immediately rises to its maximum. These operations are performed automatically by a device consisting of two commutators, U_1 and U_2, insulated from each other and mounted on a common shaft, being fitted with collector

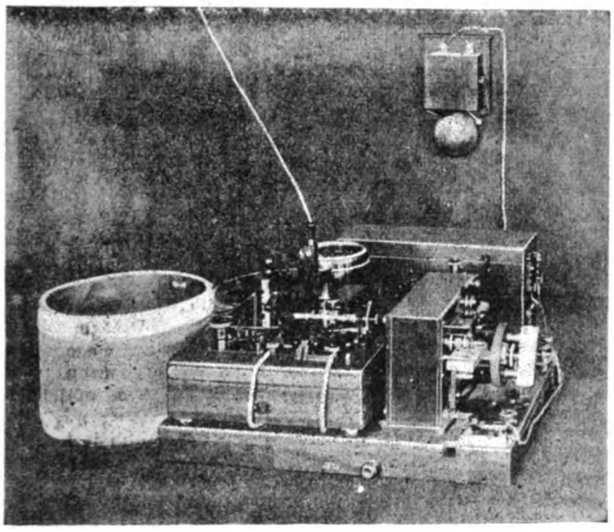

FIG. 59.—Receiving Apparatus.

rings, B_1 B_2, and on the other hand with a common brush, B_3, and makes contact alternately with the segments, U_1 and U_2, or connects them with one another. The contact device is driven by a small electric motor. This apparatus gives a pure alternating current, the frequency of which can be varied from 15 to 100 cycles per second. All the standard inductors of this company can be used with these converters by the addition of the connection P_3.

A view of the receiving apparatus for high-tension work is shown in Fig. 59. The receiver here consists of two separated circuits, which have been designated the weak current circuit and the heavy current circuit respectively. The weak current circuit includes the coherer (Fig. 60), interrupter, coherer cell, relay, condenser, regulating resistance, and make and break switch. The coherer is of special form (patented) which permits its sensitiveness to be varied at will. The ends of the silver plugs are *not* parallel, but taper. If placed with the smallest part of the opening

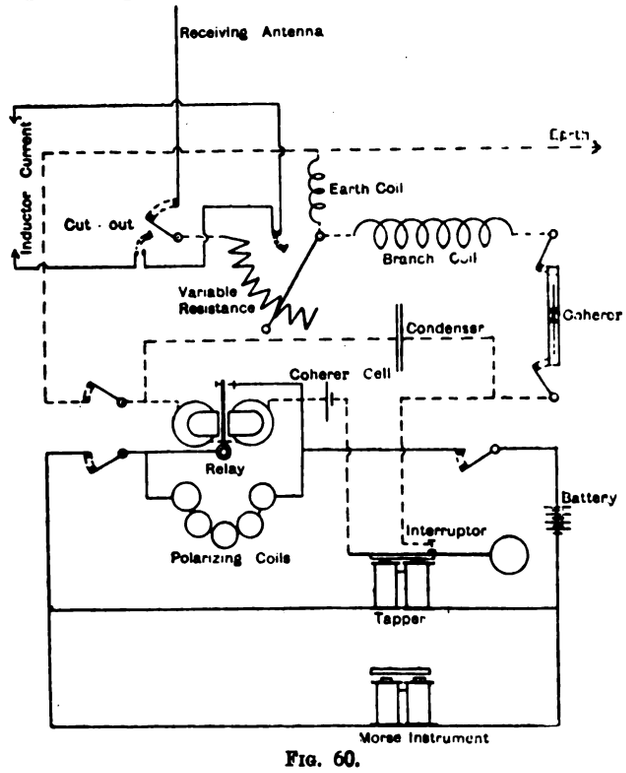

FIG. 60.

downwards the filings fill up the greater part of the space, and the coherer is then most sensitive. If the widest part of the slit is placed downwards, the powder is divided over a large surface, and the sensitiveness of the coherer is least. The "fritter" can be turned on its axis by a thumbscrew, so that any desired degree of sensitiveness can be given even when telegraphing. (The tapering ends are quite common, but the convenient means of turning the slit into any required position may be new.) The weak current circuit is shown by dotted lines, and the heavy current circuit by light continuous lines in Fig. 60. The latter includes the heavy current battery (not shown),

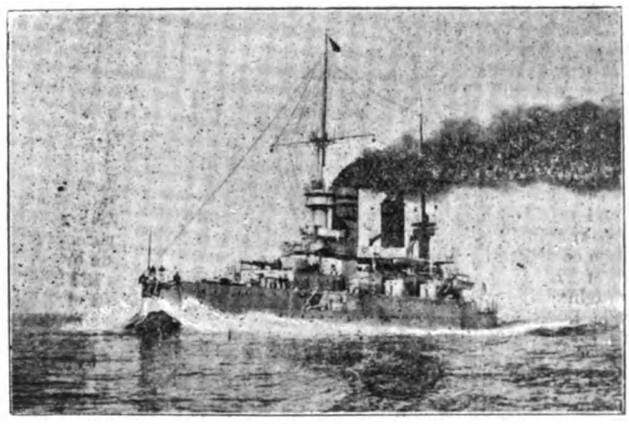

FIG. 61.—S.M.S. "Kaiser Barbarossa."

the tapper, the relay, relay working contact and tongue, polarising elements, Morse magnets, and the alarm (not shown) A microphone receiver of an interesting kind is employed when telephones are used.

The patents of this system are owned by the Allgemeine Elektricitäts-Gesellschaft, by whose permission these illustrations are shown. They publish full information, and show a fac-similie reproduction of a Morse message received

Digitized by Google

from the steamship "Deutschland" when at a distance of 150 km. (94 miles).

A warship of the German navy fitted with an installation of this system is shown in Fig. 61. The receiving and transmitting aerials will be seen attached to a sprit on the foremast.

In connection with this matter of long-distance work, Prof. Slaby gives a curve showing the height of masts or antennæ required for a given distance. From this curve the writer has deduced the following approximate *law of distance*, $h^2 = 25{\cdot}6\,d - 112$, where h is the height of aerial in metres, and d the distance of transmission in kilometres. (A kilometre is about five-eighths of a mile.) This law must not be used for values of d less than 10 or greater than 140, and holds good only for distances measured over water. It gives the height of aerial slightly in excess of the correct value (as shown by the curve) for intermediate distances. Mr. Marconi gives the law $d = c\,h^2$, where d is the distance at which the signal may be received, h being the height of the aerial (both in metres), c a number varying from 30 to 1,000, according to the nature of the receiver and transmitter employed. Recent researches made by Mr. Marconi seem to indicate the possibility of tall masts and aerials being dispensed with to a large extent in the near future.

Installations in the Arco-Slaby system have been established for the following countries: Austria, Sweden, Norway, Portugal, Russia, Denmark, and Chili, mainly in connection with their marine requirements. A very interesting station has been fitted up; it is situated on the Zugspite, the highest mountain in Germany, from whence communication is kept up with a station 2,000m. (6,650ft.) lower down.

(To be continued.)

THE SUPPLY OF ELECTRICITY BILL.

The Select Committee of the House of Lords on the Supply of Electricity Bill are now dealing with and taking evidence from the Municipal Corporations Association, the County Councils Association, and the London County Council, as well as certain gas and electric lighting companies, with reference to the proposals of the Bill.

The adjourned meeting of the conference of municipal authorities and companies owning electricity undertakings, convened for the purpose of considering proposed amendments of Electric Lighting Acts and orders, was held on Monday at the St. Pancras Town Hall, the Mayor of St. Pancras (Mr. T. H. W. Idris) in the chair.

It will be remembered that at the previous meeting a committee was appointed, and the committee subsequently passed the following resolution: "That this meeting approves the provisions of Section 1 of the Bill now before Parliament intituled 'An Act to amend the Acts relating to Electric Lighting,' authorising the compulsory acquisition of land for generating station, and that, having regard (*a*) to the report of Lord Cross's Committee in 1898 that where the site for the generating station is acquired under compulsory powers, and is specified in the provisional order or special Act, the undertakers should not be subjected to any further liability than that which, according to Lord Blackburn (Geddis *v.* Bann Reservoir, L.R., 3 A.C., 453), is imposed by the common law in the case of persons exercising statutory powers and duties; and (*b*) that it is reasonable and desirable that the nature and extent of the liability of the undertakers for nuisance should be the same as regards lands now used by them for generating stations and lands to be hereafter compulsorily acquired by them for that purpose, the President of the Board of Trade be requested to include in the Bill now before Parliament a clause to the following effect: 'All lands purchased by any local authority, company, or person, by agreement or otherwise, acquired prior to the passing of this Act and used by them for the purpose of a generating station, substation, or transformer station, shall be deemed to have been purchased by them compulsorily for such purpose, and rules shall be made by the Board of Trade under Section 5 of the Electric Lighting Act, 1882, so as to exclude the application to any such lands of Section 81 of the Electric Lighting Clauses Act, 1899, or any similar provision in any existing electric lighting order of a local authority, company, or person.'" The committee also decided to ask the President of the Board of Trade to receive a deputation from the conference in support of their views.

The **Chairman** said that Mr. Gerald Balfour had stated that he was not prepared to receive a deputation, but that, as the Supply of Electricity Bill had been referred to a Select Committee, the best course for those interested would be to present their views to the committee. The Board of Trade proposed to ask the committee which had been appointed by the House of Lords to consider the Bill, to amend Clause 6, Sub-Clause 1, by the addition of a proviso to the effect that the sub-clause should not apply to any provisional order authorising a company to supply electricity (otherwise than in bulk or for power purposes only) so far as the order related to any district in which a provisional order was in force authorising the local authority to supply electricity. The chairman had presented a petition on behalf of the conference against the Bill, submitting that, having regard to the very large expenditure which had been incurred in the establishment of generating stations and to the great inconvenience and additional expense involved by reason of their being subject to injunctions, provision should be made in the Bill whereby they might be empowered to carry on their undertakings in the same manner and with the same exemption in case of actions for nuisance as would have been the case if they had been expressly authorised by Parliament to use the lands in question for working and using generating stations and plant thereon.

The conference having confirmed the action of the chairman in presenting the petition on behalf of the conference, and thanked him for his promptness and courage, they also agreed to the following addition to Clause 1: "(4) Where any local authority, company, or person having statutory powers of supplying electricity in any area are at the date of the passing of this Act working and using, or have prior to the passing of this Act worked and used, any generating, transforming, or distributing station upon any lands not specifically authorised by Act of Parliament to be taken or used for that purpose, or have prior to the passing of this Act acquired or contracted to acquire any such lands for the purpose of erecting thereon any such station, the Board of Trade may by provisional order authorise such local authority, company, or person to use or continue to use such lands for working and using thereon a generating transforming or distributing station." It was resolved to approve the action of the Shoreditch conference in opposing Clause 6. A committee of five, with the Mayor of St. Pancras as chairman, was appointed to watch the Bill through the committee stage of the House of Lords, and they were empowered to engage counsel and give evidence before the Select Committee.

PERSONAL.

Mr. F. E. Wilkinson, of Redhill, Surrey, at present engineer-in charge of the Reigate Corporation electricity works, has been appointed engineer-in-charge of the York electricity works at a salary of £100 a year.

Mr. J. Milward, chief of the electrical department of the Pacific Cable station at Suva, is inspecting the Australian, Norfolk Island, and New Zealand stations. Mr. Milward says the Pacific Cable is working splendidly, and he has no doubt that within a short time ordinary messages will go through to London in less than an hour.—*New Zealand Mining, etc., Journal.*

Mr. Francis Edward Macmahon, inventor of the telegraph tape machine known as the "ticker," died very suddenly at Newmarket on Tuesday.

Mr. T. W. Peckham, who for the past three years has been second assistant engineer at Hastings Corporation electricity works, has been appointed assistant to Mr. Leonard Andrews, managing director of the Key Engineering Company, Limited. Mr. Peckham was formerly a pupil of Mr. Andrews at Hastings.

The Bath Town Council have agreed that the salaries and wages of the following be increased from April 1 last—namely: Mr. F. Hale, station superintendent, £150 to £175 per annum; Mr. C. S. Walker, shift engineer, from 40s. to 45s. per week; that Mr. D. T. Miles, mains superintendent, be granted an honorarium of £25 in respect of extra duties extending over a period of two years past, and an increase of salary from 65s. to 70s. per week; Mr. Northcot, £150 to £160; Mr. Shapley, £150 to £175.

TRADE NOTICES AND NOVELTIES.

New Pattern Aron Portable Meter.

The General Electric Company, Limited, 71, Queen Victoria-street, London, E.C., inform us that they are now placing on the market a new pattern Aron portable meter. This meter has been designed to meet the demand which has sprung up in connection with the management of the meter departments of electrical undertakings for a satisfactory means of checking the accuracy of consumer's meters "in situ." In a great many cases it is found that the removal of a contested meter only results in proving its accuracy, and thus entails considerable needless expense. By the use of the Aron portable standard the necessity of removing meters for testing is obviated, and the accuracy of contested meters may be proved or disproved in position. In general principle the meter is the same as the Aron meter in any of its other numerous forms, though arranged slightly differently to suit the particular class of work which it has to perform. Fig. 1 shows the general external appearance of the instrument, and Fig. 2 shows the same open and connected up by means of its flexible leads in series with another meter to be tested. The main points of difference between the standard portable and the ordinary type of Aron meter may be noted in the second illustration, and are briefly as follows: The pendulums are balanced and controlled by springs, which have the effect of making the meter more sensitive and independent of being set perpendicular, any ordinary table or floor being sufficiently level for testing purposes. The connections are all on the top of the meter case, and are plug type. The meter shown in the illustrations is arranged for 10 amperes at either 200 or 400 volts. The Aron portable standard meter can be arranged with any amperage up to 500 amperes, and any voltage or combination of voltages—

Digitized by Google

indeed, the same meter may be made to serve for 200 and 400 volts, both alternating and direct. This, of course, makes

FIG. 1.

the meter a universal standard, and, combined with its extreme portability and accuracy without special precautions as to

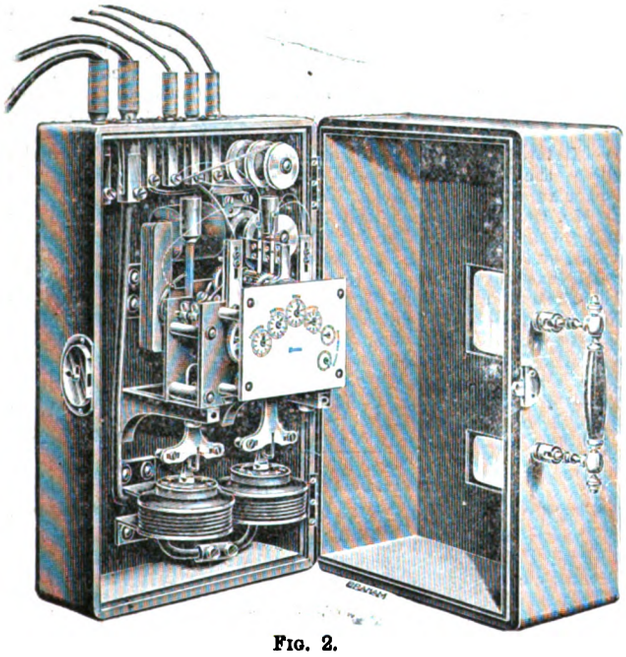

FIG. 2.

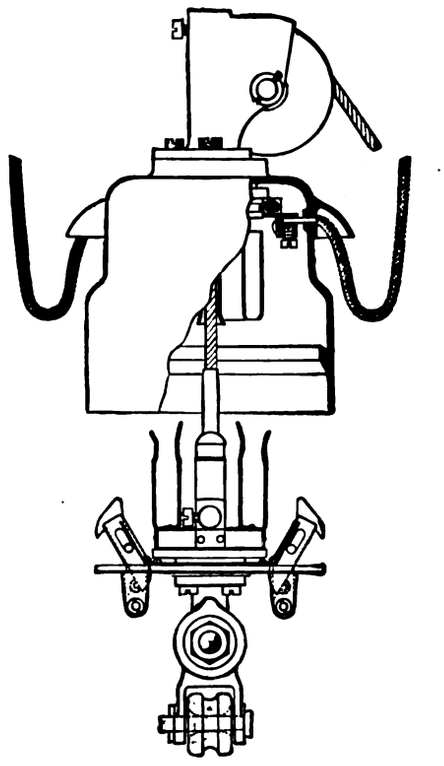
levelling, makes it a most useful instrument in any test-room equipment.

Arc Lamp Couplings.

The Bergmann Electrical Works, 6, Victoria-avenue, Bishopsgate-street Without, E.C., are placing on the market a new design in arc lamp couplings. The coupling proper consists of a cast-iron shell forming the top part. In the centre of this shell is a tube with a bell mouth, through which the hoisting rope passes, and when the lower part of the coupling carrying the lamp is raised, another tube enters this tube, thus ensuring the lower part of the coupling being quite central with the top. These two tubes are practically guides, the hoisting rope passing through the centre of both, as will be seen from our illustration. Under the weather-proof hood at the top are the two terminals; these lead to two circular contacts which are concentric with each other, the lower part having projecting lugs which make contact with the circular contacts in the top part. The contact area is ample for 20 amperes, though this is never likely to be reached in practice. Porcelain is used throughout for insulating purposes. There are also two other types, one with a device to relieve the hoisting rope of the weight of the lamp, which is set when the lamp is on the ground, and comes into operation when the lamp is raised, and another which also relieves the rope of the weight of the lamp, but acts automatically every time the lamp is raised there being no necessity to reset on each occasion, an operation likely to be overlooked if the trimmer is in a hurry. This arrangement for relieving the supporting rope consists of two catches which slip into a groove on the inside of the top part of the coupling, acting automatically every time the lamp is raised. These couplings are made with a pulley on the top of the upper half of the coupling, as shown in the illustration, so that it may be bolted to a plate or similar flat surface, where it may be fixed. The supporting rope is clipped by means of side pressure between two plates, and as the turns of the rope are of large diameter and the fastening is



independent of the sharp bend in the centre, the life of the rope at this point is longer than any other part.

Catalogues.

CRANES.—John M. Henderson and Co., King-street Engineering Works, Aberdeen, illustrates and describes the Mitchell-Williams patent compensating-derricking cranes. Fast and safe luffing has become an indispensable adjunct to all jib cranes used for modern dock, quay, warehouse, etc., work, and the great advantages to be gained by the use of the cranes, particularly on waterside work, will be apparent.

FORTHCOMING EVENTS.

THURSDAY-SATURDAY, JULY 14-16.

Association of Municipal Engineers.—At Shrewsbury, annual meeting.

GLOUCESTER ELECTRICITY ACCOUNTS.

The accounts of the Gloucester Corporation electricity department for the year ended March 31, 1904, show a total expenditure on capital account of £67,275. Appended are abstracts of revenue account, balance-sheet, and statement of electricity generated, sold, etc.

Dr. REVENUE ACCOUNT.	£	s.	d.
Generation of electricity	1,559	12	5
Repairs and maintenance of plant, etc.	152	14	2
Repairs and maintenance of mains, etc.	230	7	8
Repairs and maintenance of lamps	296	12	3
Rates and taxes	259	15	4
Management expenses—salaries, etc.	640	17	4
Insurance	48	18	4
Free wiring rental	10	8	9
Total expenditure	3,199	6	3
Balance of revenue account	3,170	18	11
	£26,370	5	2

Cr.	£	s.	d.
Sale of current, less discounts and allowances	5,964	9	10
Rental of meters and free wiring rental	173	4	7

Total maximum supply demanded (kilowatts)			1,778

Number of public lamps: 202 arc lamps, 432 incandescent lamps.

LEGAL INTELLIGENCE.

IS A CLERK A "WORKMAN"?

At Sunderland Police Court last week, Newton Cockburn, a clerk, was summoned at the instance of the Corporation on a charge of having refused to pay his tram fare. The town clerk (Mr. F. M. Bowey) prosecuted for the Corporation, and Mr. J. R. Storey defended.

The **Town Clerk** explained that on June 10 the conductor of a workmen's car, on going round to collect the fares, asked the defendant for his fare. Defendant asked for a "transfer." This was a workman's ticket, which enabled workmen to travel any distance on the system for 1d. The conductor pointed out that he was a clerk, and could not have a workman's ticket, but would have to pay the ordinary fare. Defendant refused to do this, and gave the conductor his name and address. The object of the Corporation was not to exact a severe penalty under the by-law, but simply to dispel any notion that people were entitled to take the benefit of these workmen's cars when they were not workmen coming within the section. The section relating to workmen's cars conferred benefits upon artisans, mechanics, and daily labourers, by running certain cars at such hours as might be most convenient for such workmen. Mr. Bowey quoted a dictionary definition of the word "mechanic," showing that the word applied to those who were skilled in the shaping of material, wood, or metal, etc.

Mr. Storey said that since the cars had been running to the East-end the clerks at the North-Eastern Marine Engineering Company had been getting these transfer tickets.

Colonel Reed (chairman): Because they have been doing wrong in another case, that does not affect this one.

Mr. Storey: It is a question of justification. According to the by-law, Mr. Bowey says only a man dressed in fustians and so forth is a workman.

The **Town Clerk**: I never said so.

Mr. Storey: It really amounts to this: a plater or riveter, a skilled workman earning £6 or £7 a week is entitled to get tickets for these cars, whereas a poor struggling clerk, with 20s. or 30s. a week, is debarred, simply because he has a clean collar and a black coat.

Colonel Reed: We sympathise with you, but it is the Act of Parliament we have to deal with. I don't think you will do much good by going on any longer.

The **Defendant**, in the course of his evidence, said that when he saw two other clerks, who were in a better position than himself, get workmen's tickets, he considered he was entitled to one.

By **Mr. Bowey**: He had always had workmen's tickets. He knew transfer tickets were issued from the Orphan Asylum. He had travelled on the same route, and been given a workmen's ticket since the summons was issued.

The **Chairman**, in giving the decision of the bench, said they were quite satisfied that the fare demanded should be paid, and that the defendant was not a workman, nor a mechanic, but a clerk. As the defendant had gone to some expense, he would simply be fined 1s., to include costs; but any repetition of the same offence would be severely dealt with. The public must understand that they were not entitled to travel as workmen unless they were *bonâ fide* workmen.

OBSTRUCTING A CAR.

The Colne magistrates last week heard a case brought by the Colne and Trawden Light Railways Company against a carter named Lee, who was in charge of a two-horse van, and was stated to have wilfully obstructed a car on two occasions by refusing to let it pass.

The main street of Colne, where the tramlines are laid, is very narrow for a considerable distance, and a wagon cannot pass a car except at one or two points.

The **Defendant** denied the obstruction, and on his behalf it was claimed that he had an equal right to the highway, no matter at what speed he was driving, and was not called upon to cross the road in order to let the car pass, and render himself liable to prosecution for being on the wrong side of the road.

The **Magistates** decided that there had been wilful obstruction, and inflicted a fine of 20s. and costs, but agreed to state a case.

COMPANIES' MEETINGS AND REPORTS.

BUENOS AYRES GRAND NATIONAL TRAMWAYS.

At the annual general meeting of this Company the report, of which particulars were given in our issue of the 17th ult., was adopted. In December last concessions from the municipality were obtained for the electrification of the Company's undertaking, and also the Nueva system. The work of preparation for the laying of the track in Buenos Ayres is now actively proceeding, and the Chairman believed that before the shareholders met next year the Company would have reached that great landmark in their history when 30 miles of line would have been electrified, and when they would come under new conditions as to the pooling arrangement with the Nueva Company. Mr. H. F. Gunning was elected a director in the place of Mr. R. W. Cairns who resigned.

ELECTRIC CONSTRUCTION.

The following report is to be submitted to the shareholders at the eleventh annual general meeting. The net profits for the year amount to £14,773. 1s. 2d., and, adding £4,394. 13s. 10d. brought forward from last year, the amount available for distribution is £19,167. 15s. The directors recommend that this profit be appropriated as follows:

Digitized by Google

dividend at the rate of 7 per cent. per annum on the preference shares (to be paid on July 30 next), £4,394. 12s.; dividend at the rate of 4 per cent. on the ordinary shares (to be paid on July 30 next), £8,968; to general reserve fund (which will then amount to £32,000), £2,000; balance carried forward to next account, £3,805. 3s. The year has been marked by excessive competition among the manufacturers of electrical machinery, and the Company's manufacturing profit has inevitably suffered. The competition still continues, and the margin of profit at present prices is small. The orders in the books include important contracts with the London County Council and the Great Western Railway Company. Revenue has been charged as formerly with £5,000 for depreciation, also with maintenance and all renewals of plant. The depreciation account now amounts to £53,000. The relations with the employés continue satisfactory, and the usual bonus, but reduced proportionately with the dividend, has been awarded to all who have for 12 months given good and zealous service. The balance-sheet shows an important improvement in the financial position. The Company's interest in the Crystal Palace District Electric Supply Company, Limited, which was taken over from the old Corporation has been sold; and the Madras electric tramways undertaking has been transferred to the Madras Electric Tramways (1904), Limited, in consideration of £50,000 in cash and £70,000 in fully-paid shares of that company, which, on the basis of last year's profits, should yield a dividend of 5 per cent. The cash thus realised has provided for repayment of the advance from the company's bankers. As the general reserve fund was partly made up of profit on other assets of the old Corporation previously realised, that account has been debited with £4,000 to meet the loss in realising these properties. The company's future income will benefit by these realisations. The directors who retire at the annual general meeting are Sir Henry C. Mance and Mr. J. Irving Courtenay. They are eligible for re-election. Messrs. James Meston and Co. offer a renewal of their services as auditors.

NEW GENERAL TRACTION.

The report of the New General Traction Company, Limited, for the 12 months ended March 31 last shows that, after paying £3,272 for general expenses, £9,294 for debenture interest, and £3,511 for interest on loans, a loss of £6,659. Deducting this from the balance brought forward, there remains £5,523, which is transferred to a special reserve account. In last year's report it was mentioned that measures were taken to overcome the difficulty which stood in the way of completing the Philadelphia system. Owing, however, to rigorous weather in the United States, it was not until the spring of this year that work could be resumed, and it is only within a very recent date that the directors have received cable advices that the through rail connection has been completed, so that the whole of the line should soon be open for traffic. The Parliamentary Bill for the extension of the Coventry tramway system was duly passed. A contract has been entered into by which the construction work at Coventry is now being carried out by this company. It is expected tha the new extensions will be finished before the end of the year, and the relaying of a portion of the existing old track should be completed shortly afterwards. To enable the Company to carry out these important works, to complete the Philadelphia system, and to provide for the general purposes of the Company, an issue has been recently made of £80,000 4 per cent. prior lien debentures, of which £60,000 has been subscribed at 97½ per cent. and allotted.

NEW COMPANIES REGISTERED.

Amalgamated Dry Batteries, Limited.—Capital, £20,000. Object: to adopt an agreement with B. Sherman, and to carry on the business of manufacturers and vendors of electric dry batteries, etc.

Sykes and Sugden, Limited.—Capital, £6,000. Object: to acquire the premises known as Spring-place Works, belonging to A. Sykes, in Springwood-street, Huddersfield, and the business of an electrical engineer and steeplejack carried on by him at the said premises as W. D. Berry and Sons, and to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity for light, heat, motive power, etc. Registered office: Spring-place Works, Springwood-street, Huddersfield.

Harvey and Co., Limited.—Capital, £240,000. Objects: to acquire as a going concern the business of Harvey and Co., Limited, to adopt an agreement with the said old company and its liquidator, and to carry on the business of steam, hydraulic, electric, mechanical, and general engineers, etc. Registered office: Hayle, Cornwall.

Incandescent Heat Company, Limited.—Capital, £120,000. Object: to carry on the business of designers, constructers, workers, reorganisers, and improvers of, dealers in, and advisers in respect of furnaces, heating or combustion chambers, tubes, receptacles, or surfaces, fuel or boilers, or any apparatus, plant, or arrangements connected with the problems, manner, or means of generating, applying, or using heat or fields of heat, or of obtaining combustion; quantity surveyors, draughtsmen, designers, consultants, contractors, mechanical and electrical engineers, builders, smiths, founders, glass-blowers, producers and suppliers of gas, electricity, or other power, tubemakers, etc. Registered office: 52, Gracechurch-street, E.C.

H. S. Martin, Limited.—Capital, £10,000. Object: to acquire the business formerly carried on by H. S. Martin, and recently by W. Carter, at 30 and 32, High-street, East Grinstead, Sussex, and to carry on the business of chemists, druggists, drysalters, herbalists, mineral water manufacturers, oil and colour men, importers and makers of and dealers in chemicals and apparatus for electrical, photographic, and scientific purposes, etc. Registered office: 30, High-street, East Grinstead.

Reliance Works Company, Limited.—Capital, £10,000. Object: to adopt an agreement with Sir H. A. White, and to carry on the business of mechanical, electrical, and general engineers, electro-platers, etc.

Cann, Limited.—Capital, £3,000. Object: to carry on the business of manufacturers of and dealers in automobiles, motorcars, motor bicycles, mechanical and electrical engineers. Registered office: 13 and 14, Miller-street, Camden Town.

Hunter Electric Candle-Lamp Company, Limited.—Capital, £800. Object: to acquire certain inventions relating to electric incandescent lamps and fittings and letters patent and benefit of application relating thereto, to adopt agreements with N. Burt and Co. and C. C. Regnart, and to carry on the business of manufacturers of and dealers in electric candle-lamps and fittings, etc. Registered office: 17, Newman-street, Oxford-street, W.

T. H. P. Dennis and Son, Limited.—Capital, £30,000. Object: to acquire the business of wholesale and retail ironmongers, locksmiths, bellhangers, gas and hot-water engineers, electrical and mechanical engineers, and general merchants now carried on by T. H. P. Dennis at 20 and 21, High-street, Chelmsford, as T. H. P. Dennis and Son. Registered office: 20 and 21, High-street, Chelmsford.

Lewis Motor Company, Limited.—Capital, £2,000. Object: to acquire and become licensees of patents for electric motors, dynamos, and other electrical appliances, with a view thereto to adopt an agreement with F. M. Lewis, B. P. Scattergood, C. H. Johnson, A. R. Chorley, and the Electric Construction Company, Limited, and to carry on the business of manufacturers of electric motors and dynamos and other electrical goods and appliances, electricians, electrical, metallurgical, mechanical, and chemical engineers, suppliers of electricity, contractors for the construction and equipment of tramways and railways with electric or other mechanical power, etc. Registered office: 4, South-parade, Leeds.

Paddington Electric Supply Company, Limited.—Capital, £1,000. Object: to carry on the business of electrical, mechanical, and chemical engineers, electricians, contractors, suppliers of light, heat, sound, and power by electricity, galvanism, magnetism, or otherwise, manufacturers of electric apparatus, etc. Registered office: 19, Carnaby-street, Golden-square, W.

Farnham and District Electric Supply Company, Limited.—Capital, £1,000. Object: to carry on the business of an electric light and power company in all its branches, to fix, construct, lay down, and maintain all necessary cables, wires, lines, accumulators, to construct or acquire any tramways in or near Farnham, etc. Registered office: York Mansion, Westminster, S.W.

Bishop's Stortford and Stanstead Electric Lighting Company, Limited.—Capital, £1,000. Object: to carry on at Bishop's Stortford, Hertfordshire, and Stanstead, Essex, and elsewhere, the business of suppliers of electricity for light, heat, motive power, or otherwise, electricians, engineers, contractors, etc.

Expansion Sprinkler Syndicate, Limited.—Capital, £25,000. Object: to adopt an agreement with J. Fiddes and J. F. Watt to manufacture and deal in fire extinguishers, sprinklers, alarms, and appliances, and to carry on the business of iron and steel converters, electrical and general engineers, etc. Registered office: 66, Hatton-garden, E.C.

Brentford Electric Supply Company, Limited.—Capital, £1,000. Object: to carry on the business of electrical and mechanical engineers, contractors, electricians, suppliers of electricity, manufacturers of electrical apparatus, carriers of passengers and goods, owners of railways and tramways, generators, accumulators, transmitters, etc. Registered office: Moorgate-court, Moorgate-place, E.C.

Camberley Electric Supply Company, Limited.—Capital, £1,000. All particulars are the same as in the Brentford Electric Supply Company, Limited, noted above.

Hayward's Heath Electric Supply Company, Limited.—Capital, £1,000. Object: to carry on the business of suppliers of electricity for light, heat, motive power, or otherwise, electricians, mechanical engineers, manufacturers of and dealers in apparatus and articles used in connection with the generation, distribution, supply, accumulation, and employment of electricity, etc. Registered office: Moorgate-court, Moorgate-street, E.C.

Liens Registered.

Ingleton Electric Lighting and Power Company, Limited.—Debenture registered June 27, for £600. Holder: J. C. Walker, of Ingleton. Charged on the undertaking and all the property, including the uncalled capital, but subject to prior issues of debentures for £1,200, £800, £200, and £400.

Eastern Telegraph Company, Limited, London, E.C.—Lien registered June 27, for £10,000 debenture stock, ranking *pari passu* with previous issues amounting to the total of £1,849,120. Holder: F. R. de Levanté, 141, Hill-street, Peckham, S.E. Secured by a first charge on the undertaking and revenue of the company.

APPOINTMENTS VACANT.

Rolling-Stock Superintendent, London County Council Tramways Department. Salary, £400 per annum. Applications by 10 a.m. on July 16.

Clerk of Works, Erith, Kent; construction of additions and alterations to the electric light station. Salary, £3. 3s. per week, payable monthly. Applications by 10 a.m. on July 8.

Resident Engineer, Mains Superintendent, and an Installation Inspector, a Meter Superintendent, and an Accountant, St. Marylebone Electricity Department. See advertisement.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Belfast.—The Harbour Board require two electric cranes. Tenders by July 11.

Worksop.—Tenders are to be obtained for cables, etc., for mains, and additional feeder, estimated at £1,000.

Rhyl.—The Urban District Council invite tenders for 1,400 yards of ·2 concentric feeder cable. Tenders by 18th inst.

Aurelia (Perugia, Italy).—The Municipality require tenders for an electric lighting installation by Aug. 18.

Thorne (Yorks).—The Parish Council invite tenders for lighting the town from Sept. 1 to April 30, 1905. Tenders by 14th inst.

Kingston-upon-Thames.—The Corporation invite tenders for addition to electric works building. Specification, etc., may be obtained from the Borough Surveyor. Tenders by July 14.

Batley.—The Corporation invite tenders for one 350-kw. steam dynamo and switchboard extension for same. Specifications, etc., may be obtained from the Borough Electrical Engineer. Tenders by July 16.

Halling (near Rochester).—Tenders are invited for electrical installation at the cement works of Messrs. Wm. Lee, Son, and Co., Limited, Halling. Particulars may be obtained from the Works Manager.

Plymouth.—The Education Authority invite tenders for electric light installation at the Municipal Technical School. Specifications, etc., can be seen at 11, The Crescent, Plymouth. Tenders by 12 noon on 21st inst.

Paris.—The Post and Telegraph Department, rue de Grenelle No. 103, require tenders for telegraph and telephone apparatus, telephone cables, material and chemicals for galvanic elements, etc. Tenders by July 22.

Devonport (Tasmania).—The Town Board invite tenders for the supply and delivery of alternatively 50 or 100 smallest-size meters to read direct in B.O.T. units on 220-volt direct-current circuits. See advertisement in last issue.

Felixstowe.—The Urban District Council invite tenders (Section C) extensions to feeders. Specifications, etc., may be obtained at the offices of Mr. Reginald P. Wilson, 66, Victoria-street, Westminster. Tenders by 12 noon on July 9.

Glasgow.—The Trustees of the Clyde Navigation invite tenders for two electric 32-ton coaling hoists for Clydebank Dock. Specification, etc., may be obtained from Mr. Geo. H. Baxter, 16, Robertson-street, Glasgow. Tenders by noon on July 25.

Whitby.—The Urban District Council invite tenders for (a) distributor and street-lighting cables; (b) network and service-boxes. Specifications, etc., may be obtained from Mr. H. S. King, electrical engineer. Tenders by 10 a.m. on July 18.

Acton.—The District Council invite tenders for erecting electric lighting sub-station and engineer's house, supplying wrought-iron unclimbable fencing and hurdles. Specifications may be obtained at 57, High-street, Acton. Tenders by 3 p.m. on 12th inst.

Erith.—The Urban District Council invite tenders for (1) rails, fishplates, and bolts; (2) permanent-way construction. Specifications, etc., may be obtained from Mr. C. H. Fry, Council Offices. Tenders by 12 noon on July 11. See advertisement in former issue.

Suakim.—The Public Works Department require tenders for 220 miles of galvanised wire, 1,100 yards ditto, 1,500 screws and bolts, 6,000 insulators, 1,500 creosoted fir telegraph poles, and 3,000 oak poles, to be delivered at Suakim between Oct. 1 and Dec. 1.

Dartford (Kent).—The Metropolitan Asylums Board invite tenders for installation of fire-alarms at Darenth Asylum, Dartford. Specifications, etc., may be obtained at the office of the Board, Embankment, E.C., on and after 9th inst. Tenders by 10 a.m. on 20th inst.

Wimbledon.—The Urban District Council invite tenders for extensions to the present refuse destructors at their electricity works. Particulars may be obtained from the Engineer and Surveyor to the Council, Council Offices, Wimbledon. Tenders by 10 a.m. on 25th inst.

Manchester.—The Highways Committee invite tenders for laying underground telephone pipes (Contract No. 10), with other appurtenant works. Specifications, etc., may be obtained at the City Surveyor's Office, Town Hall, Manchester. Tenders by 10 a.m. on July 11.

Aston Manor.—The Corporation invite tenders for the supply, delivery, and erection complete of pipework, etc. Specifications, etc., may be obtained from Mr. T. J. Ballard, Electricity Works, Chester-street, Aston Manor. Tenders before 12 noon on July 28. See advertisement in former issue.

Middleton (Lancs.).—The Corporation invite tenders for the supply of 3,000 tons of engine coal to be delivered at the Electricity Station, Townley-street, Middleton, during ensuing 12 months. Particulars may be obtained from Mr. S. Pauls, borough electrical engineer. Tenders by July 11.

Devonport.—The Corporation invite tenders for the supply of 4,500 tons of Welsh steam coal, delivered in cargoes of from 250 to 600 tons, for 12 months, for the electricity department. Particulars can be obtained at the office of the Borough Electrical Engineer, Newport-street, East Stonehouse, Devon.

Homerton.—The Metropolitan Asylums Board invite tenders for installation of telephones at the Eastern Hospital, Homerton, N.E., and Western Hospital, Fulham, S.W. Specifications, etc., may be obtained at the office of the Board, Embankment, E.C., on and after 9th inst. Tenders by 10 a.m. on 20th inst.

Radcliffe.—The Urban District Council invite tenders for the construction of permanent-way, including copper bonding, of about 5 miles 1 furlong of route length line, being 6½ miles single line with passing places. Specifications, etc., may be obtained from Mr. W. L. Rothwell, engineer to the Council. Tenders by 16th inst.

St. Pancras.—The Borough Council invite tenders for the supply and erection of main switchboard at the King's-road power-house, Camden Town, N.W. Specifications, etc., may be obtained at the offices of the Electricity Department, 57, Pratt-street, N.W. Tenders by 12 noon on July 19. See advertisement in former issue.

Cleckheaton (Yorks).—The Urban District Council invite tenders for the supply of various stores, including 300 tons Bowling slack to electricity works; 300 tons Featherstone washed nuts to electricity works. Particulars may be obtained on application at the Town Hall. Tenders to Mr. J. Armitage, clerk, Town Hall, Cleckheaton, before 4 p.m. on 11th inst.

Bridgend.—The Committee of Visitors invite tenders for supply and erection of a complete telephone and fire-alarm installation for the Angelton and Parc Gwyllt Asylums, Bridgend. Specifications, etc., may be obtained from Mr. W. E. R. Allen, Glamorgan County Council Offices, Cardiff. Tenders by noon on July 6. Note.—Tenders already received have not been opened.

Dartford.—The Urban District Council invite tenders for carrying out an extension of underground and pilot cables drawn into existing spareways, and for the laying of private and public lighting cables, together with all necessary roadwork, junction boxes, etc. Specifications, etc., may be obtained from Mr. W. Kay, clerk to the Council. Tenders by 12 noon on the 19th inst. See advertisement in last issue.

Warrington.—The Corporation invite tenders for the supply, delivery, and erection of steel poles, trolley wires, etc., forming complete overhead equipment for about 550 yards of double track, including special arrangements at the swingbridge over the Manchester Ship Canal. Specification, etc., can be obtained at the offices of Messrs. Preece and Cardew, 8, Queen Anne's-gate, Westminster, S.W. Tenders by 12 noon on July 12.

Bristol.—The Electrical Committee invite tenders for h.t. switchgear, water-tube boilers, two 1,000-kw. three-phase extra high-tension turbo-alternators, two 500-kw. induction-type motor-generators, e.h.t. to d.c., e.h.t. cables, e.h.t. transformers, e.h.t. switchgear. Specifications, etc., can be obtained from Mr. H. Faraday Proctor, city electrical engineer. Tenders by 10 a.m. on July 15. See advertisement in last issue.

Handsworth.—The Urban District Council invite tenders for the supply and delivery of the following in connection with the electric lighting: (4) water-tube boilers; (5) engines and dynamos; (6) overhead hand travelling crane; (7) storage battery; (8) arc lamps and posts; (9) switchboard and boosters. Specifications, etc., can be obtained from Mr. H. Ward, The Council House, Handsworth, near Birmingham. Tenders by July 11.

Derby.—The Corporation invite tenders for the making, erecting, setting to work, and maintaining in good order for twelve months on the site of the intended pumping station, of various machinery, including an electric light installation, consisting of compound high-speed engine and dynamo and sundry fittings, etc. Specifications, etc, may be obtained at the office of Messrs. James Mansergh and Sons, 5, Victoria-street, Westminster. Tenders by noon on July 13.

Rochdale.—The Corporation invite tenders for the supply, delivery, and erection at the Electricity Works, Rochdale, Lancashire, of two steam turbines direct connected to two 3-phase alternators, or alternatively for alternators connected to high-speed triple-expansion engines (Contract No. 7); and also for one motor-driven 3-phase alternator (Contract No. 8). Specifications, etc., may be obtained at the offices of Messrs. Lacey, Sillar, and Leigh, 2, Queen Anne's-gate, Westminster. Tenders by July 18. See advertisement in last issue.

Bélmez, &c. (Spain).—The *Gaceta de Madrid* of June 23 contains a notice inviting tenders for the electric lighting of Bélmez, Pueblo Nuevo del Terrible, and Peñarroya for a period of seven years. Tenders will be received by the Ayuntamiento of Bélmez on 30th inst. A provisional deposit of 582½ pesetas (or about £16) will be required from persons tendering. The adjudication will turn upon the amount to be charged by the contractor for each candle-power per month. It appears that the personal attendance of tenderers, or persons authorised by them, is required at the adjudication.

Greenwich.—The London County Council invite tenders for the supply, delivery, and erection of three 3-ton electric travelling jib cranes and two electric locomotives upon the wharf of the electricity generating station now being erected by the Council at Greenwich. The jib cranes will be operated by three-phase alternating currents, and the locomotives by direct current. Certain parts of the locomotives—viz., the motors, controllers, wheels, and axles—will be delivered to the contractor by the Council. Specifications, etc., may be obtained at the County Hall, Spring gardens, S.W. Tenders by 10 a.m. on July 12.

Lerida, etc. (Spain).—The *Gaceta de Madrid* of June 22 contains notices calling for tenders for the construction and working of telephone systems in Lérida and in El Llano del Beal, in the province of Murcia. In each case tenders are to be presented either to the Dirección-General of Telegraphs, 10, Calle de Carretas, Madrid, or at certain local offices within 30 days of publication of the notice in the *Gaceta*. In each case the concessionaire will have to pay to the State 10 per cent. of all receipts; the maximum period of the concession will be for 20 years, and the adjudication will turn on the reduction of this period. A provisional deposit of 2,000 pesetas (or about £57) is required in the case of the Lérida telephone service, and of 500 pesetas (or about £15) in the case of the El Llano del Beal telephone service.

Berga, etc. (Spain).—The *Gaceta de Madrid* for June 26 publishe a Royal decree calling for tenders for the installation and working of a

Digitized by Google

telephone system and central stations at Berga and sub-stations at Gironalla, Puigreig, Balsareny, Sallent, Castelladral y Cardona. Tenders will be received within 30 days' date of publication at the office of the Dirección-General of Posts and Telegraphs, 10, Calle de Carretas, and at the office of the Civil Governor, Barcelona, a provisional deposit of 2,000 pesetas (or about £57) being required from persons tendering. The maximum period for the concession is for 20 years, and the adjudication of tenders will turn on the reduction of this period. The *Gacetas* may be seen on application at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, E.C., any day between 10 a.m. and 5 p.m. (Saturdays 10 a.m. to 1 p.m).

Reichenberg (Austria Hungary).—The project for the establishment of a central distributing electric power and light plant in the Reichenberg land district has taken definite form. The territory included is about 10 miles square, and 24 towns and villages have joined in the movement and subscribed to the capital stock. Some 10 more are expected to join. The population of the district, exclusive of Reichenberg, is about 60,000. Stock is subscribed at present to the amount of £40,000, and this it is proposed to increase to £80,000. The principal purpose of the corporation will be the distribution of electric light and power, with the possibility of installing and working a system of suburban electric tramways. Tramway and light franchises for the city of Reichenberg are at present owned by private corporations, and at their expiration it has been generally supposed that the city would take over and conduct the enterprises. Negotiations are pending, however, which may change the situation in this respect. Communications regarding equipment, etc., may be addressed to directors Alfred Ginskey, Maffersdorf, and Dr. Richard Pirkl, Reichenberg.

RESULTS OF TENDERS.

Preston.—The tender of Mr. T. B. Garnett, at about £1,500, for offices for the electrical engineer at the electricity works, was accepted.

York.—The Education Committee have accepted the tender of J. Naylor and Son, York, at £201. 15s. 6d., for installing electric light at Fishergate school.

Perth.—The Electricity Committee have accepted the tender of Davidson and Co., Belfast, at £425, for the installation of a fan for induced draught at the electric works.

Maidenhead.—The tender of Oliver and Co., at £278, for 12 lamp-posts with arc lamps, incandescent side lamps, lowering gear, erected and painted complete, has been accepted.

Northfleet (Kent).—The tender of J. Ellingham and Sons, Dartford, at £1,497, has been accepted for levelling site, etc., for new works, for Messrs. Henley's Telegraph Works Company, Limited, at Northfleet.

Worthing.—The Corporation have accepted the tender of Rowland Bros., East-street, Horsham, at £1.689, for erection of refuse destructor buildings and chimney on land adjoining the sewage pumping station, Worthing.

Finchley.—Richard Hornsby and Sons, of Grantham, have obtained a contract for a water-tube boiler plant for the Urban District Council's Squires-lane generating station, to work alongside the existing plant, which is also of the Hornsby "upright" type.

Handsworth (Staffs).—The Urban District Council have accepted the tender of J. Elwell, Sherborne-street, Birmingham, at £142, for the supply of unclimbable wrought-iron fencing to be erected at the electric light and power station site, Piers-road, Handsworth.

Maidstone.—The Electricity Committee have accepted the tender of R. Benzie's Successors for the supply of coal from June 21 to June 21, 1905, as follows: Welsh, 20s. 5d. and 18s. 2d.; through and through, 15s. 11d. and 16s. 11d.; North Country, 15s. 3d., 14s. 9d., and 15s.

Ilford.—The Urban District Council have accepted the following tenders for extension plant: 1,000-kw. Westinghouse-Belliss, British Westinghouse Company, Limited; extension to main switchboard and extension to distributing-switchboard, Messrs. Kelvin and James White, Limited; water-purifying plant, Messrs. Lassen and Hjort; feeder pillar, etc., Henley's Telegraph Works Company, Limited.

Wiring.—The May-Oatway Fire Appliances, Limited have accepted the following tenders for wiring buildings: Hay Bros. and King's Theatre, Glasgow—Carrick and Topping; Provident Co-operative Society, Leith—W. Douglas, Limited; Adam Smail, Dundee—J. Maxwell and Son; E. Chalmers and Co., Leith—D. T. Niell and Co.; St. Mungo Manufacturing Company, Govan—Carrick and Topping.

London County Council.—The Education Committee have received the following tenders in connection with the Poplar Technical Institute: (1) a 50-kw. electric generating plant, W. Sissons and Co., Gloucester, £475* (drawings included); W. H. Allen, Son, and Co., Bedford, £520 and £5 for drawings; Mr. Peter Brotherhood, London, £541; Belliss and Morcom, Birmingham, £546 and £25 for drawings. *Recommended for acceptance.

Loughborough.—The Town Council have accepted the following tenders: Drew-Beer and Co., Westminster, at £163. 15s., for five steel roof principals required for the boiler-house at the electricity station; Ferranti, Limited, Hollingwood, £596, switchboard; J. Spencer, Limited, Wednesbury, £627. 10s., piping, feed pumps, tanks, etc.; W. T. Henley's Telegraph Works Company, London, £6,515. 2s. 5d., electric cables, maintenance at 1½ per cent.

Spennymoor.—The Urban District Council have received the following tenders: Tudhoe Gas Company, for one year £3. 4s. 6d. per lamp, three years £9 per lamp; Northern Counties Electricity Supply Company, for one year £2. 7s. 6d. per lamp, for three years £2. 5s. per lamp (accepted). The lamps to be the same size as used during the past season, except that the company propose to place the larger lamps, which have been in use during the last six months, on all the posts from the railway station to the County Hotel.

Ayr (Scotland).—The District Lunacy Board have accepted the following tenders for electrical plant: (1) Sir Hiram Maxim Electrical and Engineering Company, Limited, Collington-street, Westminster, at £829, for boiler, pump, feed-water heater, piping, &c.; (2) J. and D. Meikle, Ayr, £640, building, chimney, flues, foundations, and iron roofing; (3) Bruce Peebles and Co., Limited, Edinburgh, £1,616, engines, dynamos, and main switchboard; (4) Lowdon Bros. and Co., Dundee, £3,107, electric wiring and mains, etc.

Neath (Wales).—The Corporation have received the following tenders for the supply, delivery, and laying of electric light mains, feed pillars, and switchboards in their area:

Callender's Cable Company, London (accepted)	£1,411
Western Electric Company, London	1,351
Johnson and Phillips, Old Charlton	1,400
British Insulating Company, Prescott	1,435
Siemens Bros. and Co., Westminster	1,437
St. Helens Cable Company, Warrington	1,592
R. Alger and Sons, Newport, Mon.	1,651
W. T. Henley's Company, London	1,820

Royton (near Oldham).—The Urban District Council have received the following tenders for tramways construction:—Section A—permanent way: Hughes and Stirling, Bootle, Liverpool; J. Brunton, Hull; R. W. Blackwell and Co., Limited, London; W. Griffiths and Co., Limited, London; Edmondson and Wyatt, Oldham; G. Freeman and Sons, Hollinwood; J. G. White and Co., Limited, London; Bennie and Thompson, Warrington; Dick, Kerr, and Co., Limited, London; W. H. Worthington, Manchester; A. Graham and Sons, Huddersfield; J. E. Mayall, Oldham; W. Underwood and Bro., Dukinfield (accepted); J. and W. S. Briscoe, Stockport; G. Law, Kidderminster; Pegg and Bailey, Derby. Section B—overhead construction and equipment: F. M. Smith and Co., Limited, Salford; G. Hill and Co., Old Trafford; British Insulated and Helsby Cables Company, Limited, Prescot; W. Underwood and Bro.; Dick, Kerr, and Co., Limited; British Thomson-Houston Company, Rugby; R. W. Blackwell and Co.; Brush Electrical Engineering Company, London (accepted); J. G. White and Co., Limited. Section C—cables: Callender's Cable and Construction Company, Limited, London; W. T. Henley's Telegraph Works, Limited, London; Siemens Bros. and Co., Limited, London; British Insulated and Helsby Cables Company, Limited; W. T. Glover and Co., Limited, Manchester (accepted); St. Helens Cable Company, Limited, St. Helens; W. F. Dennis and Co., London; Johnson and Phillips, Kent; Western Electric Company, London; Simplified Underground Conductor Company, Liverpool.

London County Council.—The following tenders have been received for wiring and fittings in connection with the electric light installations for the Tooley-street fire station and the new fire stations in course of erection at Bayswater and Kilburn:

BUSINESS NOTES.

TRACTION.

Maidstone.—The new Corporation tramways were inspected by the Board of Trade yesterday.

Ripon.—The Board of Trade has confirmed the Ripon and District Light Railways Order, 1904.

Dundee.—Contracts amounting to some £760 have been awarded by the Corporation for the extension of the tramway depôt.

Tarperley.—The Light Railway Commissioners will hold an enquiry on the 27th inst. into the application for a provisional order.

Witney-Andoversford.—The Board of Trade have confirmed the provisional order for the construction of a light railway between these towns.

Liverpool.—The question of introducing a universal 1d. fare to and from all parts of the city figured in the agenda for Wednesday's meeting of the Corporation.

Paisley.—An experimental run has been made on the Johnstone section of the company's system, and proved quite satisfactory. The line only awaits the Board of Trade inspection.

North-Eastern Railway.—It is stated that there is a possibility of the company electrifying the 12 miles of suburban railway on the south side of the river between Newcastle and South Shields.

Bradford.—The Tramways Committee have considered the question of ½d. fares, and decided to make enquiries of other corporations using ½d. fares with a view to seeing how far they could be applied in Bradford.

London United Tramways Company.—Mr. Clifton Robinson has intimated that a service of cars will run from Hounslow to Hampton Court every Sunday during the summer if they are well patronised.

Horsforth.—The Urban District Council have published the statutory notice of their application to the Board of Trade for an extension until August, 1905, of the date fixed for the commencement of the tramways.

District Railway.—The Bill authorising the company to charge zone fares, and limiting luggage to 28lb., has passed through committee in both Houses, the Select Committee of the Commons giving their approval last week.

Leeds.—The Corporation have published the statutory notices of their application to the Board of Trade for an extension until August, 1905, of the date fixed for the commencement of the tramways authorised by orders of 1902 and 1903.

Bettws-y-Coed.—A petition, subscribed to by some 2,000 signatories, has been presented to the Board of Trade against the scheme for an electric service to Beddgelert, which has been submitted to the Board for confirmation by the Light Railway Commissioners.

Luton.—At the meeting of the Town Council last week the Tramways Committee presented a recommendation that Wellington-street should not be included in the tramway scheme. A motion to the opposite effect was, however, carried after a lengthy discussion.

Stockport.—The Town Council, by 23 votes to 17, rejected a proposal of the Tramways Committee to offer the Stockport and Hazel Grove Tramways Company £23,000 for their system of horse cars, in favour of an amendment that negotiations be closed without further offer.

Great Northern and City Railway.—The receipts for the week ending 25th ult. dropped to only £873. The company have opened a station at Highbury, and fixed the fares to the city at 1½d. single and 2d. return, as against 2d. and 3d. respectively of the North London Railway.

Lancaster.—A question was asked at last week's meeting of the Corporation as to whether the Tramways Committee had considered the advisability of continuing the tram line from Dalton-square to Stonewell, for which the Corporation possess powers. It appears that the committee have not yet thoroughly investigated the matter.

Nottingham.—The scheme for extending the tramways to Sneinton, *via* Manvers-street, has been adopted by the Corporation, the estimated cost being £110,000, including considerable street widening. The proposal that a branch be constructed along Forest-road has been rejected by the Corporation both on commercial and æsthetic grounds.

Barrow-in-Furness.—The Ramsden Dock section of the tramways, which are worked by the British Electric Traction Company under lease from the Corporation, were inspected and passed by the Board of Trade last week, and the cars were put into use forthwith. The Ferry branch is expected to be ready in a week or so, and will complete the system, which extends to some 7½ miles.

Chesterfield.—A special meeting of the Town Council was held last week to consider tenders for the laying of an electric tramway system 3½ miles in length from New Brampton to Whittington Moor. Particulars of the awards appeared in our last issue. The contractors undertake to commence the work within three weeks of the receipt of the order, and complete it within three months of commencement.

Poole.—Further evidence on behalf of the Bournemouth Corporation was tendered last week in connection with the arbitration proceedings between the Corporation and the Poole Electric Traction Company to decide the price to be paid for the latter's undertaking. As Mr. Lawrence, K.C., the umpire, will be engaged for some weeks as Commissioner of Assize, the proceedings have been adjourned *sine die*.

Gloucester.—At the last meeting of the Corporation a recommendation of the general manager that eight recorder clocks, similar to the one now in use at Wotton, be obtained, in order to automatically check the service of cars, was adopted. From the opening of the service up to the 22nd ult. the total number of miles run was 52,580, there were 562,151 passengers carried, and the gross receipts, £2,132. 19s. 2d., averaged 9·73d. per car mile.

Warrington.—Application is to be made to the Board of Trade for a further prolongation of time for the construction of tramways in Padgate-lane and Manchester-road. The respective tenders of Mr. J. A. Ewart for the construction of the permanent light railway No. 1 from Stafford-road to Victoria-square, Stockton Heath, at £2,935. 15s. 8d., and Messrs. Babcock and Wilcox, Limited, for the supply of four mechanical stokers at £957, have been accepted.

Lancashire and Yorkshire Railway.—An increased service of electric trains was instituted between Southport and Liverpool last Friday. Up to half-past nine in the morning there will be three electric trains only, the remainder of the service being supplied by steam trains; but between 9.30 and 4.15 the service will be exclusively electrical. In addition to the regular service, there will be several express trains, which are timed to cover the journey in 25 minutes.

Brighton.—The balance-sheet for the year ended March 31 shows a deficiency of £4,778. It is proposed to increase the fares over the longer distances from 1d. to 1½d. The present fares are considered insufficient to cover working expenses and to provide properly for depreciation. Heavy gradients necessitate the consumption of 50 per cent. more current per car mile than in most other towns. The route from the Aquarium to the railway station, *viâ* North-road, is rapidly approaching completion.

South Lancashire Electric Traction Co.—In the Palatine Court at Manchester on Monday Vice-Chancellor Hall granted an application for the appointment of a receiver in a debenture holders' action against the South Lancashire Electric Traction and Power Company. It was stated that the half-year's interest due on Jan. 1 last had not been paid, and the security had now become enforceable. Mr. John Salter, manager of the company, and Mr. Henderson, chartered accountant, London, were appointed.

Aston.—The tramway in Victoria-road is practically finished, excepting the junction where the tramway crosses Park-road, which will remain in abeyance until the line in Park-road is completed. The contractor is busily engaged in the construction of the line in Park-road, also a continuation of the line in Witton-lane. He is also making arrangements for the commencement of the reconstruction of Lichfield-road tramway, and the construction of a temporary track in connection therewith is now in progress.

South Shields.—Amended tenders have been sent to the Corporation by the South Shields Tramways Company, and Messrs. Rowcliffe and Co., who are acting on behalf of a Manchester syndicate. The former now offer an alternative tender for the construction as well as working of an electric tram system in the borough, and they also reply to the criticisms of the Corporation. The borough officials have been instructed to report upon the new tenders, which will be considered at an early meeting of the Tramways Committee.

Heywood.—The Corporation have sealed a memorial to the Board of Trade for a further prolongation of the period for the commencement of the tramways, authorised by the Corporation's 1902 order, until Aug. 8, 1905, and the period for the completion until Aug. 8, 1906, on the ground that the tramways cannot be constructed without interfering with the Manchester, Bury, and Rochdale Tramways; and by Section 38 of the order of 1902, the Corporation are prohibited from interfering with such tramways until they have acquired them, for which purpose an arbitration has been held.

Anti-Electrocution Patent.—A provisional patent has been obtained by Mr. W. E. Walmsley, of Liverpool, for a mechanical device designed to prevent electrocution on railways, which, being fitted between the sleepers at certain intervals, limits the electric current to the length of the particular section of the line on which the train may be travelling at the time. On contact with the train the device would automatically cut off the current from the section just passed and turn it on for the next section. It is credited with being easily and cheaply made, and effecting a considerable economy in current.

Bury.—The work of reconstructing the route between Bury and Tottington for electric traction will be commenced on Monday. Two sets of men will be engaged, one for beginning the work at Tottington and working towards Bury, and the other working from Bury Bridge to the centre of the town. A conference of representatives of the Salford, Bury, and Whitefield Councils has been held at Manchester with a view to arranging through running on the network of trams which will shortly connect Bury, Radcliffe, Whitefield, and Salford. Certain proposals were made which the Bury Tramway Committee will consider, and another conference will then be convened.

Westinghouse Automatic Signalling.—It is just a year since the inauguration of the Westinghouse automatic signal system on the Ealing and Harrow branch of the Metropolitan District Railway took place, and now the whole of this railway is being so equipped. A week or so ago four track circuits worked on the same principle were brought into use at the Highbury Station of the Great Northern and City Railway. This installation is the first application of the Westinghouse automatic signals on a London tube railway. The Westinghouse Brake Company, Limited, of King's Cross, carried out the installation, which, we understand, is giving complete satisfaction.

Preston.—The Corporation have referred to committee the question of restricting the service of tramways on Sunday mornings. The Penwortham, Ashton, and Deepdale section has been completed. In regard to the Ribbleton-lane route, the Corporation confirmed the Tramway Committee's acceptance of Messrs. Dick, Kerr, and Co.'s tender for the construction of the permanent way and overhead equipment. The contract amounts to £15,725, an increase of £500 on the

Digitized by Google

schedule price of the other contracts being agreed upon, as the track was at a greater distance from the town. The question of the erection of telegraph wires over the tramway wires has been referred back to committee, dissatisfaction being expressed at the result of negotiations with the Post Office.

Birmingham.—At a recent meeting of the Corporation it was stated that it would be necessary to widen several streets in connection with the tramway scheme, and this is being done where possible by reducing the footpaths, which has elicited the disapproval of a section of the inhabitants, who allege that some of the footpaths were too narrow before. A question was asked at Wednesday's meeting as to whether the conduit system could not be employed for the centre of the city, especially Corporation-street, which it was considered would be disfigured by overhead wires. The Chairman of the Tramways Committee replied that they did not wish to restrict themselves to any system, and the only objection to the conduit system was the additional expense. He added that a single line only would be laid along Corporation-street in the first instance.

Argentine Tramways.—The shareholders of the City of Buenos Ayres Tramways Company are to be asked at a special meeting to consent to the absorption of their undertaking by the Anglo-Argentine Tramways Company. The city company have for some time past been contemplating the conversion of their system from horse to electric traction, but owing to the onerous terms sought to be imposed upon them by the authorities the directors had to abandon the project. A proposal was, however, put forward by the Anglo-Argentine Company, who have obtained a concession for electrifying the line, and it is this proposal which the directors now recommend for the shareholders' acceptance. Its effect is to guarantee interest on the company's debentures and a dividend on the share capital at the same rates as paid at present. This guarantee will be a preferential charge with profits on the Anglo-Argentine Company.

Dewsbury.—Major Druitt, who conducted an enquiry into the collision of a tramcar with various vehicles at Dewsbury on May 26, states in his report that, so far as can be judged, the car was in good order at the time, and had nothing wrong with the brakes. He thinks the worst accident was caused by the anxiety of the driver to prevent the first collision, and that afterwards the driver lost his head. Major Druitt remarks that a much higher standard of training is required for men who are put in charge of electrically-worked brakes than for those who have to use purely mechanical brakes. In this connection the Westinghouse Company state that the application of their magnetic brake, or, in fact, any brake operated by electric power, is perfectly simple, and that the driver need not possess a theoretical knowledge of its working, while an electric brake takes rather less time than a mechanical one to bring a car to a stop.

Derby.—The receipts of the Corporation tramways for the five weeks ended the 25th ult. amount to £1,789. 2s. 6d. This represents a decrease of £223. 11s. 10d. as compared with the corresponding period last year, though little significance attaches to the figures in view of the reconstruction operations. The committee have decided, subject to the approval of the Council, to extend the tramways from East-street to Victoria-street, opposite the new tramway offices. The estimated cost is £2,000. The laying of the track for the new electric tramways is finished on the Osmaston route, and from Alvaston to the Midland Railway Station. Large gangs of men are now engaged on the tracks along Normanton-road and Burton-road. The lines from the Midland Station along Bateman-street and Douglas-street to the Pear Tree district are finished. On the Osmaston-road and Alvaston routes the horse trams are being utilised at present. It is expected that the scheme will be sufficiently advanced to allow the electric trams to run on the Alvaston and Osmaston-road routes next month.

The Underground.—The report of the Legal and Parliamentary Committee, presented at yesterday's meeting of the St. Marylebone Borough Council, stated that the Metropolitan Railway Company had submitted a proposal (with plans) to erect an electrical sub-station in Upper Baker-street. A sub-committee interviewed the company's engineer, and enquired if it were possible for the company to erect the proposed sub station on another part of the site, when the engineer stated that it would be impracticable, and also pointed out that unless the sub-station was constructed on, or near, the site proposed, it would be impossible to work trains by electric traction into Baker-street Station, and that the proposed improvements to this section of the railway could not be carried out unless the Council decided to favourably consider the application of the company. The Portman Estate was opposed to the site, and did not agree that the company could not find another suitable site for their sub-station. The committee recommended the Council to refuse their approval of the plans.

Belfast.—The minutes of the Law Committee, presented at the meeting of the Corporation last week, stated that representatives of the Belfast and County Down Railway Company attended the committee and expressed the willingness of that company to agree to an amendment of the Aberdeen clause of the Corporation Tramway Bill, to allow the Corporation to take out of the revenue of the lines an amount equal to that received by them at present from the Belfast Street Tramway Company for rent, interest, and rates, and to apply the balance of revenue after £20,000 had been accumulated to public purposes, and also to agree to the reinstatement of Clause 42 of the Bill as submitted to the Lords Committee by limiting it to the working of existing tramways—*i.e.*, the Belfast and Cavehill Tramway. The Corporation confirmed the resolutions of the committee that these terms be approved of, and that application be made for the reinstatement of Clause 42 in the Bill as submitted to the Lords Committee, limiting it to the working of the Cavehill Tramway. At a special meeting of the company the terms of sale to the Corporation were confirmed by the shareholders. At a meeting of the Tramways Committee on Wednesday it was unanimously agreed that the city surveyor (Mr. H. A. Outler) and the electrical engineer (Mr. V. A. H. M'Cowen) should prepare a joint report as to the relative merits of the various systems of electric traction now in use, and should submit it at the next meeting of the committee. In response to a communication from the Belfast branch of the United Carriage Company, Limited, the Chairman stated that he was sure the committee would be even more anxious than the Belfast Street Tramways Company had been to employ local labour in the construction of the cars.

Newcastle.—The progress of the Tyneside Company's Bill for inter-running powers received a check when it came up for third reading in the House of Commons last week. Sir Jas. Woodhouse moved that the Bill be referred back to committee, as there was not a sufficient public demand for a through service to justify the granting of compulsory powers. Sir W. Plummer, one of the Newcastle representatives, seconded the motion. Sir E. Strachey, chairman of the committee which dealt with the Bill, opposed, contending that through running would be a great boon to the Tyneside workmen, and that the committee had inserted a clause safeguarding the interests of the Corporation. Mr. J. W. Benn supported the resolution, observing that if the House ratified the committee's decision it would create a dangerous precedent, and one result would be that the London County Council would be inundated with applications for such powers. Mr. Bonar Law, Parliamentary Secretary to the Board of Trade, deprecated the suggestion that a great principle was involved, and opposed the resolution on similar grounds to Sir E. Strachey. Eventually the resolution was carried by a majority of 36, the number of votes for being 178 against 142. The Bill was, therefore, ordered to be sent back to the committee for reconsideration. The receipts last week amounted to £3,420, as against £3,247 in the corresponding week of last year. There were 762,075 passengers carried, as against 715,916. The Tyneside Company's Bill came before the House of Commons Select Committee on Wednesday, when it was decided to adjourn until July 19 to give the parties an opportunity of coming to an agreement respecting running powers. In the event of no agreement being arrived at, the Corporation are then to call further evidence against running powers.

Harrow and Uxbridge Railway.—The new line was formally opened on the 30th ult., when the directors travelled by special train from Baker-street to Uxbridge, inspecting the South Harrow viaduct and Ruislip station on the way. At the terminus of the branch Mr. John James Mellor, chairman of the Harrow and Uxbridge Railway Company, presided at a lunch at which there were present Sir Charles McLaren, M.P. (deputy chairman), Mr. Frederick Cox, Mr. Jabez Light, Lieut.-Colonel Olifford Probyn and Lieut.-Colonel William Terry (directors), Sir Christopher Furness, M.P., Sir Frederick Dixon-Hartland, M.P. for Uxbridge, Mr. A. C. Ellis (general manager), Mr. R. H. Selbie (secretary), Mr. A. B. Garside (assistant general manager), Mr. H. B. Palmer (superintendent of the line), Mr. W. H. Brown (goods manager), and the chairman and many of the members of the Urban District Councils of Uxbridge and Harrow. In the course of the speeches made by the Chairman, Sir Frederick Dixon-Hartland, M.P., Sir Christopher Furness, M.P., and others, reference was made to the value of the undertaking to Uxbridge for developing that town and the neighbouring district of Ruislip as residential localities. The line is seven miles long, and joins the Metropolitan Railway at Harrow and the Metropolitan District Railway at South Harrow. The power will be obtained from the Metropolitan Company's generating station at Neasden and a sub-station at Ruislip; but pending the completion of these the line is being operated by steam. The high-voltage current from the Neasden power station will be transformed at the sub station to continuous-current at 600 volts. New rolling stock of the open corridor type will be used when the line is worked electrically. There are two new stations, Uxbridge and Ruislip, and at the former there is a large goods yard, where a profitable business is expected to be done on account of the easy connections with other railways.

Leicester.—The Tramways Committee's report, recommending the purchase of 40 additional cars, the extension of car-sheds, and increased office accommodation, was presented at last week's meeting of the Council. It was stated that the new electric tramways, so far as they had been opened, had more than realised the highest expectations. They were carrying from 25,000 to 30,000 passengers per day extra. Taking the week from June 12 to June 18 they carried on the Stoney-gate line 91,266 passengers, as compared with 44,020 on the same line in the corresponding period of last year; on the Belgrave section the number was 90,738, against 32,550 last year. The 40 extra cars would bring the total number up to 100. The Tramways Committee had secured the option of ordering another 50 cars at the same price—£510 each—such option to continue until Christmas. The proposed car-shed extensions were estimated to cost £10,000, and the Board of Trade would be asked to sanction a loan to that amount. With regard to the increased office accommodation, the committee proposed to have all the staff under one roof. The estimated cost was £2,500. Since the opening of the new tramways no serious accident had occurred. The report was adopted. The Board of Trade held an inspection on Tuesday of the High-street, St. Nicholas-street, Applegate-street, Narborough-road, Hinckley-road, and Fosse-road, and the Clarendon Park-road extensions. These routes will no doubt be certified as ready for traffic. An inspection was also held of the newly-constructed permanent way in Humberstone-gate, Humberstone-road, East Park-road, Evington-road, and the completion of Aylestone-road, with the view of certifying these for public traffic. They are not yet electrically equipped, but every effort will be used to push on with the work. Aylestone-road, it is understood, will be equipped at the earliest possible moment. The inspector again highly complimented the Tramways Committee on the excellent construction of the permanent way and equipment. A main sewer has to be laid along Melton-road before that section can be commenced, and the work of laying the sewer is being hastened on.

Digitized by Google

Sheffield.—The summary of the past year's working shows that the gross profit for the year, after paying working expenses, amounts to £79,578. 17s. 5d., as compared with £71,957. 5s. 9d. in the previous year, an increase of £7,621. 11. 8d. Of this £32,874 has to go in payment of interest on loans, and £19,394 in repayment of principal, leaving a net balance of £27,309 to be carried to the accumulated surplus account. Passengers paid in 1d. and ½d. fares £232,351, as compared with £214,035 in the previous year. The income from all sources, including £912 from advertisements on the cars, amounted to £235,981, as against £216,308 in the year ended March, 1903. The total working expenses, exclusive of interest and sinking fund, amount to £156,402, or an average of 6·507d. per car mile run, as compared with £144,351 and 7·033d. per car mile in the previous year. The electric traction cost per car mile during the past year was ·139d. below the previous record, which is equal to £3,340. Passengers carried reach the enormous total of 61,450,993. Of these 49¾ millions paid 1d. fares and 11¼ millions ½d. fares. The year's increase of passengers was 4½ millions. The distance travelled by the cars was 5,768,231 miles. They have run 842,148 miles more this year than last. There are 23 inspectors, 360 motor-men, and 378 conductors. In accordance with the resolution of the Council confirming the agreement of the Tramways Committee to contribute towards the capital expenditure on street widenings and street works necessitated through tramways construction, the sums of £2,452. 13s. 3d., being proportion of interest on improvements, and of £685. 17s. for proportion of sinking fund on sundry street improvements, have been paid to the Improvement Committee this year. The Tramways Committee have paid out of their accumulated surplus £7,949. 5s. 9d. to discharge the deficiency on the district rate. The total amount contributed to relief of rates since electric traction commenced in 1897 is £50,620. 10s. 8d. The amount expended on renewals during the past 12 months has been £3,771. The committee recommend that £33,771, making a present total of £50,000, be set aside out of the unappropriated surplus towards the renewals fund. The accumulated surplus amounts to £143,369. Other details are as follows: average street miles of tramway, 31¾; traffic revenue per mile run, 9·667d.; traffic revenue per street mile of tramway, £7,318. 3s. 2d.; average number of cars running daily, 167·49; average number of passengers per car per week, 7,017; average traffic revenue per car per week, £26. 10s. 8d.; average fare per passenger, ·907d.; average total expenditure (working expenses and service of debt) per mile run, 8·682d.; average total revenue per mile run, 9·818d.; percentage of working expenses compared with income earned, 66·277; percentage of service of debt compared with income earned, 22·15; percentage of total expenditure compared with income earned, 88·427.

London County Council.—The accounts for the year ended March 31, presented at Tuesday's meeting of the Council, show that the total receipts, apart from the northern system leased to the North Metropolitan Tramways Company, amounted to £536,239. The actual working expenses were £441,786, leaving a surplus of £94,453. Against this, however, have to be placed debt charges, amounting to £100 536. 14s. 9d., for interest and sinking fund and a charge of £2.200 for income tax, leaving a deficiency of £8,283. 14s. 2d. This deficiency is attributed mainly to loss of receipts from the dislocation of traffic during the reconstruction for electrical traction. The loss of receipts under this head is estimated at about £30,000; while, in addition, the receipts were greatly affected by the exceptionally bad weather. When the estimates for the current year were passed it was anticipated that the deficiency on the working of the southern lines would be upwards of £15,000. It has also to be remembered that, so soon as capital expenditure is incurred, charges have to be met for interest and repayment of debt; and it has in some cases been found necessary to incur heavy capital expenditure on the reconstruction of tramways some considerable time before the lines can be worked electrically. The total number of passengers carried during the year was 133,139,085. As compared with the previous year's figures, when the number of passengers was 109,615,496, this year's total shows an increase of 23,523,589, which in a large measure is due to the fact that electrical cars were run on many of the lines, whereas in the preceding year a service of horse cars could only be maintained with some difficulty while those lines were under reconstruction. Of the total number of passengers 37·13 per cent. were carried at ½d. fares, 48·30 per cent. at 1d., 8·51 per cent. at 1½d., 4·67 per cent. at 2d., 0·15 per cent. at 2½d., and 1·24 per cent. at 3d. The average fare per passenger was 93d., the same as in 1902-3, and the number of car-miles run was 11,536,534, being 1,425,594 more than in 1902-3. The permanent-way has been well maintained, and the machinery, plant, and rolling-stock have been kept in thorough repair. The expenditure for permanent-way repairs, amounting in all to over £10,000, was chiefly in connection with the lines acquired from the late South London Tramways Company in November, 1902, which were in a very unsatisfactory condition. In regard to the northern system, the receipts for the year 1903-4 from the North Metropolitan Tramways Company by way of rent of the tramways, depôts, buildings, etc., amounted to £56,529. 6s. 4d., the percentage on excess of the gross receipts of the company over those of the year 1895 to £5,712. 2s. 8d., and percentage on cost of extensions, etc., to £2,516. 6s., so that the sum received from the company was £64,757. 15s.; while rents amounting to £296. 9s. were received from tenants of property in Parkhurst-road, Holloway, purchased as part of the undertaking, and miscellaneous items amounted to £7. 0s. 10d. The percentage on excess of gross receipts was less by £10 464. 9s. 10d. than the amount received from this source in the year 1902-3, but this is owing to the fact that the company had sold its lines outside the county, and the receipts from these are not taken into account in calculating the amount due to the Council under this head. The total receipts from all sources have amounted to £65,061. 4s. 10d., and the expenditure, mostly for rent drawbacks, to £794. 4s. 7d., leaving the net receipts £64,267. 0s. 3d. Out of this sum interest and sinking fund charges, amounting to £36,609. 16s. 7d., have been paid, so that the surplus revenue is £27,657. 3s. 8d. Capital expenditure, not properly chargeable to either the northern or southern system, amounting to £104,893, was incurred during the year, and the general account shows a deficiency of £10,677. The surplus revenue available on April 1, 1903, was £29,869. 6s. 5d., of which £20,000 has been applied in relief of rates, leaving a balance of £9,869. 6s. 5d. The deficiency on the southern system and the general account represent £18,965, and after deducting this from the £27,657 surplus on the northern system there remains a balance of £8,692, which, being added to the surplus from last year (£9,869), shows a surplus up to date of some £18,550. The committee's report stated that arrangements had been made for taking over the London, Deptford, and Greenwich tramways from yesterday, and asked for a special maintenance vote of £26,000. The Bridges Committee asked for £14,000 for the reconstruction or alteration of Kingaland-road bridge in connection with the electrification scheme. The design of the engines and dynamos for the Greenwich generating station, under construction by Messrs. Lovatt and Co., having been settled, the Tramways Committee recommend that the work of laying the foundations be also carried out by that firm, they having agreed to execute it at the schedule prices of the existing contract. It should be noted in connection with the annual accounts that the percentage of working expenses to receipts is far greater in the case of horse than in mechanical traction on the southern system.

LIGHTING AND GENERAL.

Cardiff.—Electric light is to be installed at St. Mary's Church, Bute Docks.

Dover.—The engineer is to prepare specification and invite tenders for free wiring.

Woolwich.—The electric mains are to be extended to the Bostal Estate, at an estimated cost of £4,613.

Wrexham.—Sanction has been received to the borrowing of £5,600 for electric mains extensions and machinery.

Erith.—The Works Committee are considering a proposal to light the secretary's and the Education Committee room with electric light.

Hove.—The Hove Electric Light Company propose obtaining a provisional order to supply current in Shoreham and south-west district.

Leeds.—At Wednesday's meeting of the City Council it was decided to apply for sanction to borrow £100,000 for electric lighting purposes.

Stockton.—The question of extending the electric lighting mains to Hartburn, Norton, and Eaglescliffe is before the electrical engineer for report.

Wells.—The Mutual Electricity Supply Company intend to apply for a provisional order to enable them to supply electricity within the Town Council's area.

Black Sea Cable.—The Black Sea cable between Odessa and Constantinople passed in the hands of the Indo-European Telegraph Company on July 1.

Redditch.—The report of the Lighting Committee recommending that application be made for permission to raise a further loan of £8,500 has been adopted.

Kingswood.—All opposition to the Kingswood electric lighting provisional order having been withdrawn, it has been referred to the Select Committee on Unopposed Bills.

Crewe.—The Town Council have decided to apply for sanction to borrow £4,500 for enlarging the plant at the electricity works. About 70 new consumers are waiting to be connected.

Llanelly.—The Llanelly Borough Council are corresponding with the British Insulated Wire Company with regard to the electric lighting order, which they fear might be cancelled by the Board of Trade.

Bridgend.—A rebate of 2½ per cent. is to be allowed to consumers of electric light who paid their accounts within one month after they become due. The number of consumers has increased from 69 to 71.

Derby.—The analysis of revenue receipts and expenditure of the electric lighting departments for the year ended March 31, 1904, shows a net profit of £1,719. 10s. after payment of interest and sinking fund.

Chorley.—We understand that the Town Council have accepted the offer of Mr. Oswin Hansom to take over the Chorley Electric Lighting Order, 1898, on payment of £384, the costs incurred in obtaining the order.

Burnley.—A letter from the wholesale and retail trades section of the Chamber of Commerce, asking for a reduction of the charges for current, has been referred to a sub-committee of the Electricity Committee.

South Shields.—The sum of £1,303. 16s. 8d., representing the net profits on the electric light undertaking, after deducting £300 already transferred to the general district rate account, is to be transferred to the reserve fund.

Inverness.—Edmundson's Corporation have paid £2,386 to the town, the sum due under the contract. They intend to apply for a provisional order in terms of agreement, and a site which they have purchased for a generating station has been approved.

Bridlington.—The Town Council have decided that the price to be charged for electric current supplied from the generating station (when completed) should be 5d. per Board of Trade unit for lighting purposes, and 3d. per unit for heating and power purposes.

Electric Construction Co.—The net profit for the year ended May 31 amounted to £19,167, including £4,394 brought forward,

Digitized by Google

The directors recommend a dividend at the rate of 4 per cent. on the ordinary shares, place £2,000 to reserve, and carry forward £3,605.

Birkdale.—The Birkdale District Electric Supply Company have agreed to supply current for lighting the hospital at 2d. per unit. The draft agreement *re* flat rate for supply of electrical energy for lighting purposes for the district has been approved by the Urban District Council.

Cromer.—The chairman and directors of Edmundson's Electricity Corporation on Monday invited their customers and many of the principal inhabitants to an official inspection of their electricity supply works, which was largely attended. The works were opened by the chairman of the Urban District Council last year.

Gravesend.—The Council have decided to apply for a provisional order to extend the area of supply defined by their order of 1898, so as to include part of the area of the urban district and parish of Northfleet. This will not in any way interfere with the negotiations between Gravesend and Northfleet already referred to by us.

Newquay.—The committee recently appointed to consider the question of electric lighting have recommended that the Southern District Corporation be informed that it was not the intention of the Council to erect arc lamps for public lighting, but to utilise the present lamps with the unrust burner, should the system be adopted.

Cannock.—At Tuesday's District Council meeting the Chairman gave an explanatory statement with regard to the proposal to establish electric lighting for the district, and, subject to approval, an agreement with Messrs. Whittaker Bros., of Dudley, for carrying out certain works is to be signed. The site of the proposed works is at the rear of the Council offices.

Liverpool.—At Wednesday's meeting of the Town Council it was decided to apply for sanction to the borrowing of a further sum of £400 000 for purposes connected with the supply of electrical energy, £325,000 being for work that the committee have already been ordered to do by the Council; the remaining £75,000 is to be put at the disposal of the committee to go on with.

Meter Testing.—The meter department of the Electrical Company, Limited, 121 to 125, Charing Cross-road, W.C., have just issued a handbook on meter testing, with the definite purpose of making the method of testing the accuracy of the company's meters perfectly clear, and to give details of such information as is mostly asked for by those unacquainted with these particular meters.

Worthing.—The last report of the resident engineer contains the following figures: number of applications to date, 314; consumers connected, 281; equivalent number of 8-c.p. lamps (private) applied for, 17,597; number connected, 15,617; total number connected (including public and private), 18,000; number of motors on circuit, 18, and aggregate capacity of same, 108 h.p.

Metropolitan Electric Supply Co.—The directors recommend a bonus of £6 per share, payable on July 19, to holders of ordinary shares, out of profits on capital account made by the sale of the St. Marylebone undertaking. At an extraordinary meeting, to be held on the same date, the chairman will explain the views of the Board as to dealing with the balance of the purchase money.

Electric Power Storage Co.—The directors have declared a dividend of 6 per cent on the ordinary shares for the year ended May 31 last. The profit for the year, including the balance of £594 brought forward, is £10 360. Out of this sum the directors have carried £3 500 to the reserve fund and £1,000 to the contingent fund, which will absorb a further £5 339 and leave £470 to be carried forward.

Devonport.—The Devonport Corporation will now supply electricity for lighting, power, and heating purposes at the following scale of charges—viz.: lighting—not exceeding 1,000 units per annum between April 1 and March 31. 4½d. per Board of Trade unit net; all units in excess of the first 1,000 units per annum, 4d. per Board of Trade unit net; power and lighting, 2½d. per Board of Trade unit net.

Hull Telephones.—There are indications that the suggestion of the Hull Incorporated Chamber of Commerce that public telephone call boxes should be placed at the local and suburban railway stations will shortly be carried into effect. The National Telephone Company have already made application to place a call box at Paragon Station, and applications are also being made for placing call boxes at four other stations.

Glasgow Telephones.—The Corporation telephone accounts for the past year show a surplus of £3,650, which is carried to depreciation account, this now standing at £5,743. The net revenue was £49.639, showing a balance over expenditure of £20,519. Of this £8 525 was absorbed for interest and £8,343 for the sinking fund. The capital outlay now amounts to £30,782, and there are unexhausted borrowing powers of £50,000.

Bangor.—At last week's meeting of the City Council the electrical engineer's salary was increased by £40 per annum. In the meantime Mr. Percy White has been appointed consulting electrical engineer in connection with the Carnarvon Corporation electric lighting scheme. On Wednesday it was agreed that the engineer be allowed to undertake the commission for the Carnarvon Corporation conditionally that the increase in his salary be postponed until April, 1905.

Perth.—The accounts of the electricity department show a revenue of £5,764, and an expenditure of £3,380, leaving a balance at the credit of the sinking fund account of £1,425. There is a debit balance of £49 602 on the borrowed money account, and £700 at the credit of the contingent account. In the general balance account assets and liabilities are put down at £52,926. In the estimates for the current year the unit is reduced from 4½d. to 4d. to private consumers.

Gloucester.—The electrical engineer has reported on the capacity of the existing lighting plant, pointing out that, after making allowance for stand-by, next winter's load would probably be equal to the full capacity of the existing plant, and that the committee should without delay arrange for the installation of the additional plant which would be required at the end of the year 1905. The Works Sub-Committee have been requested to consider and report upon the matter.

Bognor.—The Urban District Council have asked the Board of Trade, as the extension of the Electric Lighting Order, 1899, would expire on June 30, to defer further consideration of the question of revoking the order for six months to enable the Council to make the necessary arrangements for providing electric lighting in the town. Mr. V. Collinson, of Leadenhall-street, London, has given notice to apply to the Board of Trade to supply electricity within the urban district.

York.—The Electric Light Committee recommend the Council to authorise the extension of mains throughout Coney-street and Spurrier-gate. With a view to evading, as far as possible, any inconvenience to traffic, the city electrical engineer is to confer with the city engineer. A demand for current having arisen on Holgate-road it is proposed to lay a main from St. Paul's Church to the Fox Inn. The extension works at the station on Foss Islands will be formally opened on Monday afternoon, July 18.

St. Marylebone.—The technical legal difficulties which had arisen respecting the form of receipt, and in consequence of which the St. Marylebone Borough Council were unable to complete the purchase of their electric lighting undertaking on June 30, have now been settled. According to a promise by Mr. J. Wilson, town clerk, the deed was to be brought before the Council for sealing last night. The Council have made arrangements for a temporary loan of £1,300,000 at 3½ per cent. per annum to enable them to complete the purchase.

Stowmarket.—The town has now been placed in telephonic communication with Ipswich, Woodbridge, Felixstowe, and the trunk lines throughout the country by the National Telephone Company, Limited. Ordinary messages can be sent from the call office to Ipswich, Woodbridge, or Felixstowe at a charge of 2d. for three minutes; to London the charge will be 1s., and Bury St. Edmunds 6d., for the same length of time. There will also be an exchange and call office at Needham Market within the next few days.

Lancaster.—The report of the electricity department shows a total net profit of £1,506, as compared with £1,353 for the previous year. Of this sum £750 has been paid over to the borough fund and £756 carried to reserve fund; the latter now stands at £4,241. The total for sale of current and rent of meters has increased by £1,681; the income from public lamps is also more by £76. The total expenditure has increased from £5,796 to £7,559, the increase in interest and redemption being £762. The total capital expenditure is £60,595.

New Firm.—We are informed that, owing to a steady increase, the business hitherto carried on by Mr. F. Winter, 8, Redcross-street, in supplies for electrical and general manufacturing purposes, will now be carried on under the title of Dr. Heinr. Traun and Sons' London Agency, with Mr. F. Winter as manager and Mr. G Almenräder as assistant manager. Mr. Almenräder has been with the firm for the last 18 years, and although there is a formal change of name the business will be carried on here and elsewhere by the same persons and in the same manner as heretofore.

Coventry.—An enquiry has been held into an application of the City Council for power to borrow £31.675 for the purpose of the extension of the electric light works. Mr. Jeckell said that the amount for which sanction to borrow was applied for would be distributed as follows: mains, £12 000; new sub-stations completely fitted, £200; transformers, £3 000; new generating plant at works, £6,725; boiler, £1,159; crane, £450; buildings, £1,500; foundation, £250; feed pumps, £250; pipes, £500; extension of coal conveyor, £300; extension of economiser, £300; motors for works, £150—total, £31,757.

Luton.—The electrical engineer reported at the last Town Council meeting that since May 16 last 10,561 units had been generated, an equivalent to 68 8-c.p. lamps and two motors of 2½ h.p. connected, making a total of 169 consumers with 10,795 lamps and 52 motors of 177 h.p.; and at the present time over 356 additional lamps and three motors of 5½ h.p. were being wired. The number of units generated showed an increase of 76 per cent. over the number generated during the corresponding period of last year. Extensions of mains, estimated to cost about £326 and £248 respectively, were dealt with in committee.

Rathmines.—The accounts of the Electric Lighting Committee show an apparent loss of £955 for the last year. The Council are supplying electric light to private consumers at 4½d.; the cost is 3·87d. Public lighting is charged 2·7d. It is suggested that the public lighting should be charged at the same rate as to the private consumers. The total credit for public lighting last year was £2,979, but if charged at 4½d. it would amount to £4,965, and instead of showing a loss of £955 on the year's manufacture, it would show a credit balance of £1,034. The matter has been referred to the Electric Lighting Committee.

Maidstone.—An extension of 170 yards of mains is to be made in King Edward-road at an estimated cost of £68, and 15s. will be charged per lamp per annum for the hire of lamps for outside lighting of shops, the consumer paying for the electrical energy. The last electricity financial statement shows that the value of electricity supplied for quarter ending March 31, 1904, was £2,241; collected, £2,007; balance, £236; overdraft on revenue account, £692; temporary loan on capital account, £1,341; temporary loan on motor account, £804; temporary loan on free wiring, £381—£2,528—total, £3,220.

Retford.—At the meeting of the Town Council on Friday the Gas Committee presented a report as to the advisability of supplying electricity in the borough. They estimated five miles of cables to cost £3,000, the erection of a plant at the gasworks to run 2,000 lights at £6,000, and a building for three engines at £500. With regard to the cost of production the estimates were: fuel and gas, £250 a year;

Digitized by Google

wages, £250; and £100 for extras. The Gas Committee, with the addition of five members of the Council, were appointed to engage an expert to go over the town and submit to an early meeting a scheme and detailed information.

Manchester.—At Wednesday's meeting the Chairman of the Electricity Committee (Mr. Howarth) said the electricity undertaking had, so far, not been a great financial success, but the prospect was brightening. In two years the amount of electrical current generated had gone up from 10 million units to 29 millions, mainly due to the completion of the tramways, but there was also an increasing demand for electricity for power purposes from industrial companies and firms. In the early days of the Manchester electricity department, he said, the committee had gone a little too far with their expenditure on capital. This it was which made the profit at present look somewhat small.

Kilmalcolm.—A provisional order was obtained by the local electric light company in 1903, and the supply was started last Christmas, which practically forms a record in having the supply started in same year as provisional order was obtained. The town is practically built on rock, and therefore a great amount of blasting was required for opening tracks for laying of cables. Already over 100 consumers are now connected to the supply mains, and, we are informed, applications are still coming in. Considerable extensions are to be made to the supply mains and station plant to meet increased demand for next winter. The resident engineer is Mr. James Brown, late of Govan.

Dudley.—The Electrical Committee propose that a 400-kw. engine and dynamo be purchased from the Ferranti Company and installed at the generating station. Also that the charge to consumers of power be reduced to 1d. per unit for 22 hours, and 6d. for the hours of heavy load. The electrical undertaking's output for the year ending March 31 last shows an increase of 470,000 units, compared with that for the previous 12 months. The gross income for the year was £10,661, and the working expenses £5,649. The gross profit was £5,012, of which £4,356 was absorbed in principal and interest on loans, leaving a net profit of £655. The net profit for the previous 12 months was £396.

Torquay.—The Town Council on Tuesday instructed the electrical engineer to prepare drawings and general scheme for the proposed new electric light and power station in Upton Valley, having regard to the fact that the Dolter Tramway Company's Bill has passed the committee of the House of Lords. The total amount of the Council's capital outlay in connection with the new electricity station, to supply the Dolter Company with current, will be £10,000, of which £8,000 is for machinery. The minimum sum payable by the company, £1,200 per annum, is more than required to pay the costs of generation, interest, and sinking fund charges upon this £10,000, while the Council will benefit in other ways.

Neath.—An enquiry has been held into an application of the Corporation to borrow £5,000 for electric light purposes. The Town Clerk said the Council obtained a provisional order in 1901, and had entered into an agreement with the South Wales Electrical Power Distribution Company, who would be in a position to supply current in September. A tender of Messrs. Callender Cable Company at £1,412 had been accepted. Mr. D. M. Jenkins, borough engineer, concurred with the estimate of Mr. Henry Thomas Sully, Bristol, the consulting engineer, of 40,000 units. A number of people had given their names as customers. It has been suggested to light the new public library and the market, now under construction, with electricity.

St. Annes.—Mr. J. H. Clothier, the electrical engineer, in his report for the month ending June 25, says: Since the last report we have received 11 applications for 396 lights. There is an increase of 50 per cent. in units sold for private lighting compared with the corresponding month of last year, whilst the lamp connections and consumers still continue to increase at an even rate. Units sold during May, 1903, 8,868; 1904, 42,694; units sold to May 31, 1903, 21,503; 1904, 87,477; equivalent to 8-c.p. lamps connected, 1903, 11 348; 1904, 14,568; units sold per 8-c.p. lamps connected, 1903, 0·78; 1904, 0·61; maximum load lighting, 1903, 107 kw.; 1904, 147 kw.; ditto traction, 1903, nil; 1904, 400 kw.; total number of consumers, 1903, 186; 1904, 264.

Stock Exchange.—The Stock Exchange Committee have appointed July 20 as a special settling day for Rhodes Electrical Manufacturing Company's 6,133 ordinary shares of £1 each, fully paid, Nos. 35,001 to 41,000 and 43,101 to 43,235, and 33,000 vendors' ordinary shares of £1 each, fully paid, Nos. 5,001 to 35,000, 41,001 to 43,100, and 43,236 to 44,135. Application has been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to London United Tramways (1901), Limited, further issue of 25,000 5 per cent. cumulative preference shares of £10 each, fully paid. The committee have also been asked to appoint a special settling day in Marconi's Wireless Telegraph Company's further issue of 25,000 shares of £1 each, fully paid, Nos. 196,128 to 221,127.

Newton Abbot.—The Urban Electric Supply Company's electricity works were opened on Monday by Mr. H. T. Parker, chairman of the Lighting Committee of the Urban District Council. Messrs. Parker Bros. were the contractors for the work. The plant consists of dynamos giving 180 amperes at 500 volts, and batteries of a capacity of 360 amperes. At present there are 6,800 8-c.p. lamps in use. Owing to the number of applications received this number will shortly be increased to 7,300 lamps. The street-lighting includes 20 10-ampere arc lamps and three 3-ampere enclosed arc lamps; 117 40-c.p. half-night lamps, 101 40-c.p. all-night lamps; 26 80-c.p. all-night lamps, and a single 160-c.p. lamp. There are 18 electric motors connected with the cables. Mr. F. C. Pay is the managing engineer, with Mr. Dayian as assistant engineer.

Southwark.—The Guardians have accepted the following offers: (*a*) City of London Electric Lighting Company, Limited, for lighting Board-room and offices. In each of the two winter quarters: for the first six units per 8-c.p. lamp, 5d. per B.O.T. unit, and 2d. per unit for any excess in each quarter beyond six units per 8-c.p. lamp; in each of the two summer quarters: for the first three units per 8-c.p. lamp, 5d. per B.O.T. unit, and 2d. per unit for any excess in each quarter beyond three units per 8-c.p. lamp. (*b*) London Electric Supply Corporation, Limited, to supply current to the new northern relief station and dispensary, 81, Borough-road, for 12 months certain, and thereafter, subject to three months' notice on either side, at the price of 4½d. per B.T.U., and to allow a discount of 5 per cent, for prompt quarterly settlements.

Pamphlets for Distribution.—Mr. H. F. Friederichs, electrical engineer to the West Hartlepool Corporation, has recently issued two handy and efficient pamphlets, entitled "Electricity for Lighting Purposes," and "Electricity as a Motive Power." They were originally got out with the idea of counteracting the effects of the pamphlets distributed by the local gas company. As these identical pamphlets are being widely distributed by the various gas companies in this country, Mr. Friederichs considers that he has attained the end he had in view, and at the same time the Corporation's electricity undertaking obtained a good advertisement. We are asked to say that if any station engineer would like a copy it is to be had for the asking, and he is at liberty to alter the contents to suit local conditions, and to use it if helpful to the cause it was originally got out for.

Ealing.—At the last meeting of the Town Council the Electricity Supply Committee reported that a scheme formulated by Captain Purvis for the formation of a fire brigade at the works was considered, and it was resolved to provide a steam siren, extra hydrants, chemical extincteur, and fire pails at a cost not to exceed £50. Fifteen men to form the brigade, and to be paid 6d. per hour for attending drills (not during regular working hours), the maximum cost of drills for the first year being £5. 12s. 6d. and subsequent years £4. 10s. It being suggested that Captain Gravener should be informed of the arrangements made, so that he might co-operate with the brigade at the works in the event of a fire, it was said the committee would willingly avail themselves of Captain Gravener's help if he could be of any assistance to them; but if a fire should occur at the electric lighting station it must be put out in a few seconds, and the staff there should be drilled as to what switches they would have to break, etc.

Mirfield.—The Urban District Council have signed an agreement with the Yorkshire Electric Power Company for the supply of electricity in bulk from the company's new station at Thornhill. The agreement is of a somewhat novel character, as the Council are undertaking the lighting supply, and allowing the company to supply direct to large power users who require motors. Thus the Council are saved a heavy expenditure on a generating station and electrical mains, and it is confidently anticipated that the undertaking will prove profitable from the commencement. The Council's consulting engineer, Mr. A. B. Mountain, of Huddersfield, after considering the question of putting down a small generating station to supply the district, recommended the taking of a supply from the company. The negotiations have been carried out by Mr. E. B. Wilson, clerk to the Council, and Mr. W. B. Woodhouse, the company's chief engineer. A supply of electricity will be available at the end of the year

New Issue—Electric Supply Corporation, Limited.—This company acquires provisional orders for the supply of electric light and power in 18 towns in England and Scotland, and the prospectus now issued is remarkable for the absence of any claim for promotion profit. It is stated that the entire capital of £250,000, in ordinary shares, will be applied to meeting the actual cost of plant and machinery and preliminary expenses; and a very advantageous agreement has been entered into with Messrs. Crompton and Co., Limited, who have contracted to carry out all the works at a profit of 15 per cent. on the prime cost. It is estimated on the basis of results in similar districts, that the company will be able to earn 10 per cent. on its ordinary shares, which have no preference shares in front of them. The business at Chelmsford, which is taken over as a going concern, has been very successful, and encourages anticipations of equally good returns in the other towns in the earlier days of development. Out of these five have recently commenced supply, and the erection of plant and laying of mains will be immediately proceeded with in the remaining districts. The agreements with the local authorities, under which the undertakings may be purchased on the expiration of varying periods, ensure favourable terms to the company. The list of applications will open on Tuesday, 12th inst., and will close on Friday, 15th inst.

Maidenhead.—As it will be some time yet before the Royal Assent will be given to the extension order, the Council have decided to apply at once for power to borrow £3,000 for the extensions carried out and projected in the original area. Messrs. Burstall and Monkhouse estimate this as follows: Plant at station—cooling tower, pumps and pipes, grease separator, etc., £607; mains—new town feeder, £450; extensions of distributing mains in Bath-road, Rutland-road, Cranford Villas-road, Norfolk-road, over Maidenhead Bridge, Boyn-hill-avenue, St. Mark's-road, £530; provision for new extensions, £400; public lighting—arc lamps in Bath-road, £330; additional incandescent lighting, £216; services and meters, £400; cost of loan, stamps, contracts, etc., £67—£3,000. Their recommendation that as soon as the Royal Assent has been given the districts adjacent to the present area should be proceeded with has been agreed to. These would be Maidenhead Court, Bray, and Taplow from the river to the Dumb-Bell, and they would require a capital expenditure of about £3,000, and could be served from the plant at present in the station by extensions of the existing mains. The outlying districts of Taplow, Hitcham, Burnham, Cookham, Cookham Dene, Holyport, etc., will require special mains and machinery. The last report of the resident engineer shows that the public lighting extensions are now rapidly progressing. The outside department has been very busy with consumers, 10 new services having been laid, nine of which have been connected up. Application for 674 8-c.p. lamps have been received during the month, being more than was anticipated in the last report. The total number of lamps applied for now stands at 12,700.

Yarmouth.—There were some remarkable figures disclosed in a set of tenders examined by the Education Committee on Tuesday for installing the electric light into certain schools. For Northgate School one firm asked £86, the next highest tender was £121, then came one of £170, after that £179, and finally £182. For Nelson School the prices quoted varied from £40 to £83. For St. George's School the differences were startling, for while the lowest figure was £48, the next highest was £62; then came £93, after that £96, followed by £104, with £150 as the top price. Tenders for the Priory School ranged from £73 to £176, an equally startling discrepancy, and for St. James's School from £43 to £107. The accepted tenders appear in another column. The committee have stated, in explanation of the different quotations, that local firms had not enough hands to do the work in the time, but the accepted firm was a large concern, and was, therefore, able to quote so much more cheaply. Its figures were within £5 of the estimate of the borough electrical engineer.

Kensington.—Applications received from the Post Office for permission to lay pipes for telephone wires, etc., in Colville-terrace (south side), Walton-street (north-west side), West Cromwell-road (north side), Hogarth-road (north-west side), Earl's Court-road (north-east side), and North-row (south-east side), and notices from the undermentioned electric lighting companies relative to proposed extensions—viz.: Notting Hill Electric Lighting Company, Limited, Colville-square, Colville-gardens, Powis-square, Talbot-road, and Colville-terrace; Brompton and Kensington Electricity Supply Company, Limited, Barkstone-gardens and Richmond-road; have been agreed to. The Council have received a letter from the Willesden Urban District Council stating that they have been memorialised by a number of ratepayers and residents in the Harrow-road to light such road by means of electric arc lamps, and enquiring whether, in the event of the District Council agreeing to such request so far as their side of the roadway is concerned, the Borough Council would be prepared to so light the section of the road under their control.

West Bromwich.—In their last report the Electricity Committee stated that in August, 1901, the Council fixed the price of electrical energy for power purposes at 1d. per unit. The committee had since found that in the case of motor installations of 3 h.p. and under, the income at the present charge was not sufficient to cover sinking fund and interest on the average cost of a service, and therefore recommended that for all motor installations of 3 h.p. and under the consumers should be given the option of an increase of ½d. per unit in the charges or pay for a minimum consumption of 200 units per horse-power per quarter. Also, in cases where light and power are used on the premises, the current for power purposes shall be registered by the lighting meter, the indicator being placed in the lighting circuit only so that all current used for power will be charged for at the 1½d. rate. They further recommended that application be made for sanction to borrow £1,300 for further mains extensions. Sanction had been received to loans of £1,751, £548, and £1,000 for extensions, street-lighting, and effecting other necessary improvements.

London County Council.—On Tuesday it was agreed to lend the Bermondsey Borough Council £31,000 for electric lighting and dust destructor purposes, and the Shoreditch Borough Council £7,000 for electric light installation. A report was submitted concerning the proposed erection of a generating sub-station at Streatham and the acquisition of a site, involving an expenditure of over £21,000. The site chosen by the Highways Committee is adjacent to the Wandsworth Borough Council's depôt. It contains an area of about 22,000 square feet, and has an entrance from the private road at the side of the Council's depôt, and also a frontage to Daysbrook-road in the rear. The owner being willing to dispose of the land for £1,500, the Council agreed to pay that amount for it. The cost of erecting the sub-station is estimated at about £7,500, and the provision of plant, etc., at £12,000. Notices under Electric Lighting Acts and orders were agreed to as follows: Crystal Palace District Electric Supply Company, to lay high-tension mains along portions of Sydenham-road, West-hill, and Charleville-circus, and to build a transformer box at the junction of West-hill and Crystal Palace Park-road; Brompton and Kensington Electricity Supply Company, to lay low-tension mains along a portion of Richmond-road; Charing Cross and Strand Electricity Supply Corporation, to build a street box at the junction of the Haymarket and Pall-mall East; County of London Electric Supply Company, to lay low-tension mains along Baakerville-road; London Electric Supply Corporation, to lay high and low tension mains along portions of New Cross-road, Billington-road, and Briant-street, and to fix a converter box in Billington-road; Metropolitan Electric Supply Company, to lay extra high-tension mains along portions of Great Chapel-street and Carlisle-street from Titchfield-street to Dean-street; Notting-hill Electric Lighting Company, to lay mains along portions of Colville square, Colville-gardens, Colville-terrace, Talbot-road, and Powis-square; St. Pancras Borough Council, to lay mains across Stanhope-street and along portions of Drummond-street, Hampstead-road, and Tottenham Court-road, and to lay mains along a portion of Tottenham Court-road.

London Gazette.—A receiving order has been made out on debtors petition in the estate of Frederick William Parkes and Edward Sadleir (trading as Parkes and Sadleir), electrical fitters and engineers, trading at Dingle, Colwyn Bay, Denbigh. An order has been made to wind-up the Electro-Voelker Syndicate, Limited, 65, George-street, Croydon, Surrey. The following committee has been appointed to act with the official receiver and liquidator of the Automatic Telephone Company (1903), Limited: Andrew James Crane, The Bungalow, Seabrook, Hythe, Kent; George Augustus Paul, 110, Capel-road, London; James White, 43, Gordon-square, London; Charles Gregory Penney, 70, Bishopsgate-street, London; John Dixon Gibbes, 38, Weymouth-street, London. The partnership between George Ernest Mansfield and William Goddard Dexter, electrical engineers, 84, Vulcan-road, Leicester, trading as Mansfield and Dexter, has been dissolved by mutual consent; George Ernest Mansfield will continue the business. The partnership between Thomas Usher and William Schmahl, 6, Farringdon-avenue, London, E.C., and Newcastle-upon-Tyne, trading as Armorduct Improved Electric Conduit Company, has been dissolved by mutual consent. The partnership between James Herbert Edwards, Frank Armstrong, Alfred Langrish Stephens, and William Dillworth Armstrong, electrical and mechanical engineers, Bristol, Cardiff, and elsewhere, trading as Edwards and Armstrong, has been dissolved by mutual consent; James Herbert Edwards and Alfred Langrish Stephens will continue the business. The Lincoln Tramways Company, Limited, will be wound up voluntarily; Edwin Pratt, Clarence House, Lindum-terrace, Lincoln, has been appointed liquidator. The Louis Leakey Aluminium Company, Limited, will be wound up on account of liabilities; Mr. James Fitzpatrick, 147, Leadenhall-street, London, E.C., has been appointed liquidator. The partnership between John Altman and Stanley James Rising, trading as the Metropolitan Lighting Company, 157, High-road, Kilburn, has been dissolved by mutual consent. The final meeting of the Dover Electricity Supply Company, Limited, will be held at the Burlington Hotel, Dover, at 12.30 p.m. on Aug. 3.

Robertson Electric Lamps Outing.—In order to mark the completion of another successful year the staff and employés of Robertson Electric Lamps, Limited, Hammersmith, chartered a special last Saturday and betook themselves to Dover and Folkestone. Those who went to the former place had an opportunity of witnessing some of the festivities in connection with Lord Curzon's installation as Warden of the Cinque Ports. There were about 400 in the train, all as jolly as sand boys, though most of them were girls; we have at various times seen them at work, cheerfully and diligently pursuing their allotted tasks, and it may be taken for granted that they did not lack application when on pleasure bent. It speaks volumes for the management and all concerned that there was not the slightest hitch or annoying incident barring a slight accident, which deserves to be noted as it arose from a singular cause rather significant of the times we live in. On the return journey an accumulator battery of bottles remained for some time an unsolved problem, as amongst the whole party, Pressmen included, not a single corkscrew could be found. The programme, which was carried out with lavish hospitality, included, as far as the staff was concerned, a dinner, for the success of which compliments are due to Foster's Dover Castle Hotel, followed by a most delightful drive. A well-appointed four-in-hand, supplemented by a drag, first took the party through shady Kentish lanes to Newing Green. Here an old-fashioned garden was found, full of luscious strawberries, also a bowling green, some swings, etc., all of which found their use in turn to while away a pleasant hour in the glorious sunshine. The next halt was made at Limpne Castle, and, while admiring the extensive view, the party, which had spread out picnic fashion, fell the victim to Mr. Robertson's camera. A thoroughly enjoyable drive through Hythe, Sandgate, and the Undercliff finished up again at Fosters, where tea was laid. As in the morning Mr. C. J. Robertson, director, and Mr. C. Wilson, manager, took the chairs. There were practically no speeches. Mr. Heeden, one of the superintendents proposed "Success to the Firm"; Miss Fuller, holding a similar position, proposed a well-deserved vote of thanks to the secretary of the organising committee, Mr. G. W. Saville White, which was carried by hearty acclammation. Mr. Wilson welcomed the visitors, who were unanimous in having had a splendid time aided by the jovial goodfellowship which permeated the gathering. This was the eighth outing of the firm, and, with the exception of additions, there were no new faces to be seen. A similar remark was made with regard to the employés, showing that the firm's policy of encouraging dinner and recreation clubs, social evenings, &c., is bearing fruit.

Dover Hydraulic Bridge.—On Saturday the inspector of the Board of Trade, Major-General Hutchinson, C.B., attended to witness the running of the first train over the new branch railway from a junction in the Harbour Station, over Strond-street, along Union-street, across the entrance to the Wellington Dock by the new steel bridge, continuing across Cambridge-road and the Esplanade, to the Prince of Wales Pier, and along the pier to the new Port of Call Station, 500ft. long, which has been erected near its extremity. The run, says the *Dover Express*, to which we are indebted for the following particulars, was a success gratifying to all concerned. The new railway from the Dover Harbour Station to the Prince of Wales Pier, which is a single line 24 chains in length (80 chains make a mile), has been constucted for the Dover Harbour Board by Messrs. Pearson and Son, Limited. Mr. Walmisley has acted for the Harbour Board as consulting engineer. The main feature of the new line is the electric hydraulic bridge over the Wellington Dock entrance. This bridge, which is formed of two cantilevers, is of mild steel, having a total length of 134ft. 11½in., the portion that swings across the dock entrance having a radius of 91ft. 1½in. from the centre pivot, and the rear portion being 43ft. 1in. long. The total weight of the bridge, which was built by Messrs. Armstrong, Whitworth, and Co., of Elswick, near Newcastle-on-Tyne, is 300 tons. It carries a single line of railway, and the bridge, which has a clearance of 17ft. between the cantilevers, will permit two horse vehicles to pass each other with plenty of clearance. It is decked with karri wood, covered with bluegum treads, and iron ways for the wheels of vehicles. On the west side there is a cantilever path for foot passengers, with a width of 4ft. 11in. from the centre of the main girder. Such a big bridge requires considerable power to manœuvre it, and the method by which this is applied is very interesting. In a small engine-house beside the brick tower is an engine actuated by electric power derived from th Corporation mains. This works a 12in. ram in the adjoining tower which pushes an accumulator to the top of the tower, which is 45ft. high. This accumulator is loaded with 29 tons of ballast. The weight of this falling produces an hydraulic pressure of 750lb. per square inch, necessitating pipes with specially devised connections to convey the power to the bridge. The machinery is capable of opening and shutting the bridge at least 10 times an hour. The bridge is carried on an

Digitized by Google

hydraulic centre pivot, which raises the bridge when required to be swung 3in. or 4in., so as to clear its bearings. The bridge, on being raised, cants up at its further extremity, the back part being loaded with Kentledge cast out of the old bridge. On the bridge being lowered it becomes horizontal. The turning of the bridge is effected by a ring 16ft. diameter under the bridge, to which is attached a big chain. To turn the bridge the quarter of a revolution that is necessary to open it, this chain has to be hauled a distance of 12ft. The chain being passed over a sheaf, is attached to an hydraulic ram, which has a movement of about 6ft., and this is sufficient, owing to the chain being doubled, to move the chain 12ft. and cause the bridge to make the necessary quarter turn to open it. The hydraulic pivot of the bridge rests on a granite block, and this in turn rests on a 6ft. square block of concrete which is taken down on to the solid rock 22ft. below. General Hutchinson, one of the Board of Trade inspectors, who made the test both of the bridge and the viaduct, has reported that both the viaduct and the bridge are quite safe, and the railway is fit for traffic. The viaduct, under the influence of a load greater than two engines, deflected only $\frac{1}{16}$ft., whilst the deflection on the bridge was only $\frac{1}{8}$ft., the span there being considerably more. The results of these tests are considered exceedingly satisfactory, and the whole work does great credit to both the designer and the constructors.

COLONIAL NOTES.

Kingston (Jamaica).—An accident occurred on Monday in the power-house of the electric works. A large pipe conducting water into the works burst at a time when 60 men were working in the building, and all were swept into the adjacent river by the inrush of water. It is reported that 34 men were drowned, while 17 others are missing.

Rand Central Electric Works.—Result of working for June: "Kilowatt-hours generated 949,835, yielding a gross revenue of £8,800." For the corresponding period of last year the result was: kilowatt-hours generated 675,241, yielding a gross revenue of £6,136. *Financial Times.*

Mian Mir.—Four of the tenders for the installation of electric light and electric punkah-pulling, Mian Mir Cantonment, are under the consideration of the Director-General, Military Works.—*Indian Engineering.*

New Zealand.—The Waipori Falls Electric Power Company, Limited, intend to present a petition to the General Assembly of New Zealand at the ensuing session praying for leave to introduce a Bill to authorise the company to supply and use electrical energy within the counties of Taieri, Bruce, Tuapeka, and Waikouaiti, the city of Dunedin, the boroughs of Milton, Mosgiel, Green Island, Caversham, South Dunedin, St. Kilda, Mornington, Roslyn, Maori Hill, North-East Valley, West Harbour, and Port Chalmers, and the road districts of Peninsula, Tomahawk, and Portobello, and to undertake all works necessary for that purpose. The *New Zealand Mining, Engineering, and Building Journal* says: "The Wellington Press were furnished with some amusement over the various engineering disputes and mistakes in Otago's capital. But the Empire City has its own little troubles, and one has just arisen which the law courts may be asked to solve. The point is whether the electric syndicate under its agreement with the City Council has the monopoly of supply of electric light and power for the city. The City Council claims that the syndicate has no monopoly, and that they can compete with the syndicate. Certainly if the syndicate did not secure themselves against competition from their own concessionaires then they were much less prudent than business people generally are."

PROVISIONAL PATENTS, 1904.

JUNE 27.

14433. Improvements in electric ignition, lighting, and battery charging systems, parts of which are applicable for other purposes. Ivon Molesworth de Havilland, 18, Hertford-street, Coventry.

14442. Improved means for electrically connecting railway rails or other conductors. John Stirling Alexander, Fife House, Kingston-on-Thames.

14460. Improvements in or relating to the reduction of the difference of phase in electric current circuits. James Yate Johnson, 47, Lincoln's-inn-fields, London. (Badische Anilin and Soda Fabrik, Germany.)

14463. Improvements in or relating to electromagnetic apparatus for opening, closing, or short-circuiting electric circuits. Valère Alfred Fynn, 70, Chancery-lane, London.

JUNE 28.

14500. A method of chemically treating arc-lamp carbons whereby all wastage is stopped on same while lamp is burning and life of carbon is considerably increased and better distribution of light obtained at arc. Albert Ernest Carter and Cecil Charles Fowler, Corporation Electricity Works, North-road, Brighton.

14504. Improvements in and connected with electrolytic cells. James Hargreaves, May Villa, Peel House-lane, Farnworth, Widnes, Lancs.

14510. Improvements applicable to the "trolley poles" of electric tramcars. Frank Nicholson, 4, St. Ann's-square, Manchester.

14519. Automatic electric rail protector. Henry Sanderson, 99, Laygate-lane, South Shields.

14520. Improvements in branch connections for electric cables. Franklin Everhart and John Joseph Dossert, 46, Lincoln's-inn-fields, London. (Complete specification.)

14523. Telephone systems. Wallace Fairweather, 65, Chancery-lane, London. (American Electric Telephone Company, United States.) (Complete specification.)

14543. Improvements in thermo-electric couples. William Henry Bristol, 23, Southampton-buildings, Chancery-lane, London. (Complete specification.)

14544. Improvements in thermo-electric couples. William Henry Bristol, 23, Southampton-buildings, Chancery-lane, London. (Complete specification.)

14545. Improvements in thermo-electric couples or apparatus. William Henry Bristol, 23, Southampton-buildings, Chancery-lane, London. (Complete specification.)

14553. Improvements in electric burglar alarms. Amos Getto, 53, Chancery-lane, London. (Complete specification.)

14567. Improvements in electricity meters. Isaac Octave Revilliod, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

14568. Arrangement of electric cable working with high voltage. Siemens-Schuckert Werke G. M. B. H., Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, June 29, 1903, being date of application in Germany.) (Complete specification.)

14577. Improvements in liquid lift controllers or resistances for use with either alternating or direct-current circuits. Ernest Daniel Knights, 18, Buckingham-street, Strand, London.

JUNE 29.

4663A. Improved means for rupturing electric currents. Percy Holbrook Thomas, The Westinghouse Patent Bureau, Westinghouse Building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, June 27, 1903, being date of application in United States.) (An invention comprised in application No. 4663, dated Feb. 25, 1904.) (Complete specification.)

14597. Improvements in and relating to time switches for electric current, gaslight, or similar purposes. Frank Simon Smith and John Henry Smith, Imperial-chambers, Albert-street, Derby.

14617. Improvements in the contacts of electric wire connections. Edward Lycett, 77, Colmore-row, Birmingham. (Complete specification.)

14663. Improvements in and relating to electromotor driving. Sebastian Ziani de Ferranti, 18, Southampton-buildings, Chancery-lane, London.

JUNE 30.

14684. Improvements in and connected with dynamo-electric machines. Henry Oliver Farrell, 106, Princess-street, Manchester.

14717. Improvements in insulating electric conductors especially suitable for the firing plugs of internal combustion engines. John Leighton and Ernest Hacking, 24, Southampton-buildings, Chancery-lane, London.

14727. Improvements in and relating to electric railways. Joseph Cook Angus, 70, Chancery-lane, London.

14728. A gravity controlled electric current indicator with a long range of movement. William Joseph Still, 63, Lincoln's-inn-fields, London.

14733. Improvements in electric arc lamps. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

14734. Improvements in electric arc lamps. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

14735. Improvements in electric arc lamps. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

14736. Improvements in and relating to electric cut-outs and the like. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

14737. Improvements in dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

14738. Improvements in dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

14739. Improvements in brush-holders for dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

14740. Improvements in electric meters. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

14741. Improvements in protection against reversal of energy. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

14743. Improvements in or connected with electric or other railways. John Edward Neale, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

Digitized by Google

14761. Improvements in or relating to driving gear for electrically operated cranes, trolleys, travelling winches, and the like. Herbert John Haddan, 18, Buckingham-street, Strand, London. (Martin Becker, Germany.)

14762. Improvements in electromagnetic operating devices for levers, valves, and other mechanism. Herbert John Haddan, 18, Buckingham-street, Strand, London. (Martin Becker, Germany.)

JULY 1.

14767. An improved nipple for use in connection with electrical conduit tubes and fittings. Hugo Hirst and Charles Edward Gunner, 71, Queen-Victoria-street, London. (Complete specification.)

14770. Improvements in electric light reflectors. Hugo Hirst and John Hillery Collings, 71, Queen Victoria-street, London.

14786. Improvements in and connected with the supply of electric current to the "live" rail or wire of electric traction systems. George Wordsworth Peard and Ambrose Mitchell Martin, 15, Water-street, Liverpool.

14792. Electric railway automatic feeding appliances. Ernest Rothwell, 71, Great Cheetham-street West, Manchester.

14814. Improved clip for clamping or binding the trolley wires to fittings in overhead wire systems of electric traction. John Henry Luby and William Harris, Lloyds' Bank-buildings, Bristol. (Complete specification.)

14815. Improved section insulator for overhead wire systems of electric traction. John Henry Luby and William Harris, Lloyds' Bank-buildings, Bristol. (Complete specification.)

14821. Improvements in and relating to electro-capillary apparatus. James Tarbotton Armstrong and Axel Orling, 61, Chancery-lane, London.

14841. Improvements in and relating to the regulation of dynamo-electric machines. Allgemeine Elektricitäts-Gesellschaft, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, July 2, 1903, being date of application in Germany.) (Complete specification.)

14847. Improvements in electrical fire alarms and thermo-indicators. Casimir Cyon, 40, Chancery-lane, London. (Complete specification.)

JULY 2.

14879. Improvements in and relating to apparatus for controlling the lighting and extinguishing of gas, the flow of fluids, or the actuation of electric switches, and for analogous uses at predetermined times. Harry Wightman Harris, 55, Chancery-lane, London.

14911. Improvements in electric arc lamps. Adolphe Bellardent, 18, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Sept. 5, 1903, being date of application in France.) (Complete specification.)

14918. Improvements in and relating to automatic telegraphic apparatus. Antoine Damaskinos, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published July 21, 1904.

1903.

14062. Electrical cash-checking machines. Guess.

14175. Gas or vapour electric apparatus, such as mercury vapour lamps and converters for lighting or other purposes. Le Tall. (Cooper-Hewitt Electric Company.)

14190. Wireless telegraphy. Brown.

14247. Electric resistances. Von Kramer.

14363. Telephone call recording systems. Lake. (Automatic Telephone Meter Company.)

15243. Means for automatically regulating electric currents generated by dynamos. Watkins. (Consolidated Railway Electric Lighting and Equipment Company.)

20633. Attaching electrical insulators to insulator brackets. Chambers.

20634. Attaching insulators to the tubular arms of telegraph and like poles. Chambers.

23863. Electric distribution systems. Hallberg.

26721. Cohering receivers used in space telegraphy. Peters.

28401. Electric arc lamps. Perdrisat.

1904.

707. Electric block-signalling systems. Werner.

1314. Electric igniters for explosion motors. Ropiquet and Daveluy. (Date applied for under International Convention, May 30, 1903.)

3426. Electric switches. MacDiarmid and Bates.

4394. Brush-holders for dynamo-electric generators. Deutsch.

6389. Electrical distribution. Woodbridge.

7129. Telegraphic signal systems. Burke.

8235. Systems of electrical distribution. Peck. (Date applied for under International Convention, May 1, 1903.

8986. Electrically propelled road vehicles. Soc. Anon. L'Electrique. (Date applied for under International Convention, Jan. 14, 1904.)

8612. Transmission of electrical impulses. Richmond.

10058. Electric switches. General Contracts Company, Limited, Cook, and Chipperfield.

10142. Electrical conductors. McGeorge.

11471. Dynamo-electric machines. Siemens Bros. and Co., Limited. (Siemens und Halske Actiengesellschaft.)

11862. Electric arc lamps. Haddan. (Allgemeine Beleuchtungs und Heizindustrie Actiengesellschaft.)

12087. Prepayment electrical measuring instruments. Conrad. (Date applied for under International Convention, June 24, 1903.)

NOTES.

X-Rays.—Prof. Bozzoli, director of clinical medicine at the University of Turin, has communicated to the Royal Academy of Medicine his observations on the result of the use of X-rays in the treatment of certain serious diseases of the blood. He states that their action was very efficacious, enabling him to effect a cure in a case of leuchæmia which was considered incurable.

Rontgen Society.—The annual general meeting of this institution was held on the 7th inst., when the report and balance-sheet were adopted, and officers elected for the ensuing year. It may be mentioned that the council have arranged that the library of the society, at 19, Hanover-square, shall be open to members for reference every Thursday afternoon, from 5 p.m. to 7 p.m. Members are invited to send to the librarian any contributions of interest—books, journals, skiagrams, tubes, etc.

Wireless Telegraphy.—It is reported that the reason for the rejection by the Argentine Government of the Marconi Company's proposals to erect a radiographic station in the republic was that the Government considered the terms proposed by the company too high, and that the technical department of the Argentine telegraph service advised this course on the ground that the benefit derived from the station would not compensate for the cost of its installation. The Government, it is said, viewed the matter entirely from the commercial standpoint, and were not influenced by any other considerations.

New Publications.—"The Universal Directory of Railway Officials, 1904" (London: The Directory Publishing Company, Limited. 10s.). The latest edition of this volume has been carefully revised, and additions have been made relating to many parts of the globe. Practically all the mechanical tramways of the United Kingdom are included.—"Ready Reference Tables," by Carl Hering (London: Chapman and Hall). This, the first of a series of volumes in preparation by the author, deals with conversion factors, and, within the limits of a moderate-sized and elegantly-bound production, contains a quantity of information.

Electricity in Mining.—A lecture was delivered last Saturday at Bridgend by Mr. W. A. Scott, of Cardiff, to the Mid-Glamorgan Association of Colliery Managers on the subject of the application of electric power in mining operations. The great economy, said Mr. Scott, accruing from the adoption of electric power in place of steam and compressed air, when transmitted to a distance, such as to underground haulage gears and pumps, was a long-established fact, but it was only now being recognised that its application to all purposes on the surface, including main winding engines, showed remarkable results in the saving effected in steam and coal consumption. Although nothing had been done in this country in the way of installing large electric winding engines, quite a large number were at work in Germany, and Mr. Scott described in detail the plant laid down at the chief mines in that country, the lecture being illustrated by lantern views.

Annual Dinner of the Day Students of Northampton Institute.—This annual event took place on July 8 at Anderton's Hotel, Fleet-street. The chair was taken shortly after 8 o'clock by one of the students, Mr. W. Stanley Lonsdale. Among the guests present were the Principal (Dr. R. M. Walmsley, M.I.E.E.), Dr. C. V. Drysdale, M.I.E.E., Mr. C. E. Larard, A.M.I.C.E., A.M.I.M.E., Mr. S. Field, A.R.C.Sc., with their respective senior lecturers and assistants. Altogether 42 were present. After the dinner a very good programme had been arranged, the toasts and musical items being interposed. In reply to the toast of the "Institute and Principal," Dr. Walmsley gave some very good advice to the leaving students, especially as to what could be learnt in works from practical men. Dr. Drysdale, in replying for the electrical department, corroborated Dr. Walmsley's remarks, and made some humorous allusions to the "self-induction and resistance" of students. Mr. Larard, for the mechanical department, was also very humorous in his remarks, and his advice, both as regards works and social instincts, should be carefully borne in mind by all those present. Mr. Field, in replying for the chemical department, pointed out the importance of a good knowledge of electro and metallurgical chemistry to the engineer, as a lot of metals, etc., important to him were now being largely produced by electrolytic means. He took aluminium as an example. With several very good songs, and pianoforte solos, by the students a very enjoyable evening was brought to a close.

A Telephone News Bureau.—A telephone bureau was recently inaugurated in Philadelphia by the *Evening Telegraph* of that city in conjunction with the Keystone Telephone Company, by which the 15,000 local subscribers to the company can be supplied with information gratuitously upon almost any imaginable subject. The scheme of distributing news by telephone which has been in operation for several years at Budapest entails the use of a separate telephone system, but the Philadelphia undertaking is served by a branch exchange. The switchboard for the bureau was installed under the direction of Mr John W. Kelley, superintendent of the Keystone Telephone Company. A few particulars concerning it are given in the *American Telephone Journal*. It consists of a horizontal central energy board, and is equipped with 20 incoming trunks and one outgoing trunk. The instrument equipment consists of seven portable desk sets and four breastplate transmitter sets, all having head band receivers. The board is so arranged that it can be operated with one or 20 operators, as needed, by means of switching keys. An enquirer calling for the exchange s c onnected with a trunk that is not busy, bringing up the lamp signal. When possible, a reply is given at once, but if it is necessary to look the answer up, a shunt key is thrown into circuit, holding the signals at the telephone office. On an average over 2,500 questions, which are of a very cosmopolitan character, are answered daily, and on some occasions the number has reached nearly 4,000.

Radial Emanations from Mineral Springs.—Some determinations of the radio-activity of gases given off by mineral waters have lately been made by M. Curie, samples of the gases collected at different mineral springs being sent to his laboratory in well-sealed flasks. After drying, the sample of gas is placed in a closed brass cylinder, which forms the outer part of an electric condenser. The inner part of the condenser is a brass rod placed in the axis of the cylinder and well insulated. The cylinder is given a charge of 200 to 300 volts, and the inner rod is connected to an electrometer. The gas, which becomes a conductor owing to the emanation it contains, allows a certain current to pass from the cylinder to the rod. The current is set up as soon as the gas is admitted. It increases somewhat rapidly for several hours, owing to the formation of an induced radio-activity on the inside surface of the cylinder. The current then decreases slowly, and this generally occurs about 24 hours after the introduction of the gas. The rate of decrease is the same as for the radium emanation. M. Curie made a table for the gases of different mineral springs of Europe. The numbers correspond to the current measured after leaving the gas 12 hours in the condenser. For the purpose of comparison,

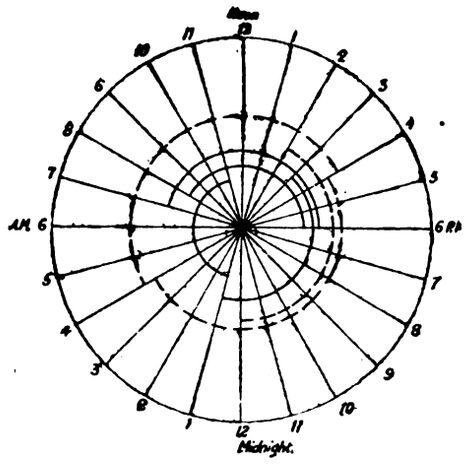
Digitized by Google

a solution containing 0·00001 grm. of radium bromide was used, from which the emanation which had accumulated was drawn off by means of a current of air. It was found that the water from Bad Gastein (Austria) has by far the strongest emanation, represented by the figure 360. Next come four samples of water from Plombières (France), at 47, 29, 28, 21 respectively. Banis les Bains and Luxeil (France) show 16 and 5·7. It is considered that at the actual springs the activity would be twice as strong.

The Use of Exhaust Steam for Generating Power.—According to the *Elektrotechnische Rundschau*, No. 17, a new process for utilising exhaust steam with a view to producing power in low-pressure steam-turbines, including an exhausted accumulator (Rateau patent), has been developed by Balcke and Co., Limited, Bochum, Germany. The device is especially intended for utilising the exhaust from intermittently working engines used in mining. While an ordinary condensation in most of these engines will have but a very slight effect (the vacuum in the cylinders being of no importance, and considerable condensation losses being caused by a high cooling of the steam cylinder during stoppages), the new outfit will allow of the exhaust from these machines being utilised to such an extent as to secure a better saving than, for instance, in the case of a satisfactory condensation in a high-class triple-expansion machine. The exhaust steam from a hauling machine will readily allow of 500, and that from a reversing machine of 1,000 electric horse-power being generated. Moreover, the first cost is much lower than the one of a high-tension steam plant of the same output, while there are practically no expenses for operation. The principle of the process consists of storing the exhaust steam issuing in very variable amounts from the intermittently working engines in an exhaust steam accumulator, and of transmitting same in a uniform manner to a low-tension turbine. The latter, after receiving the steam, as a rule at atmospheric tension, will give it off again at the condenser tension. In the accumulator the exhaust steam has a pressure ranging from ·15 to ·3 atmospheres higher, the pressure varying within these low limits along with the charging and discharging of the apparatus.

Rubber Production.—A recent report of the United States Consul at Mexico City discusses the outlook for rubber culture in Mexico. His conclusions do not encourage the idea that rubber can be cultivated profitably in that country. It was thought that the Castilloa elastica, which is being cultivated in Mexico as a shade tree for coffee plantations, might be used to produce rubber, but apparently the tree does not flourish in that clime; and even assuming that the tree could be cultivated successfully, it is considered that the expense of collecting the juice would be greater than that of obtaining it from wild trees. Plantations would have to be cleared and the trees planted and protected for a number of years, after which the milk would have to be carefully harvested by paid labour, instead of being collected by the natives in their unvalued time, as is done with wild trees. Further, it is said that as yet no satisfactory method of coagulating the milk of the Castilloa elastica has been discovered, and the experiments necessary to devise one would probably entail considerable expense. More optimistic is the report of the United States Consul at Bangkok, Siam, in which country rubber cultivation has recently been started, some thousands of plants of the Para variety having been set out as an experiment. These are said to be showing excellent progress, although they have had no special attention, and the United States Consul expects to be able to report before long that the venture has proved highly successful. He also calls attention to two rubber-producing plants indigenous to Siam, and known to be of commercial value—the Ficus elastica, and a plant considered to belong to the Urceola species. These plants, which grow with remarkable rapidity, yield very well, and it has been suggested that they could be profitably cultivated in the Philippines.

Circle Diagrams for Facilitating Economical Working.—In a recent number of *Electricity* (New York) some circle diagrams are contributed by Mr. R. Grieves to illustrate the arrangement of the different shifts of men in relation to the time of operating different machines and different kinds of apparatus, with a view to ascertaining whether the maximum efficiency is being obtained from the staff, by arranging the men's hours of working so that each man is at all times worked to the best of his ability. In preparing these diagrams, faint concentric circles are drawn, the number of such circles depending upon the number of men or the number of machines, engines, boilers, or generators under consideration, each man or machine being given one circle. From the centre 24 radial lines are drawn, representing the hours of the day. When several different classes of employés are to be considered, or when different kinds of apparatus, or the time of operating different kinds of apparatus, are to be shown on one diagram, different kinds of lines are used to distinguish them. Four diagrams are given in our contemporary, the first, which we reproduce, illustrating the arrangement of the staff. The solid lines

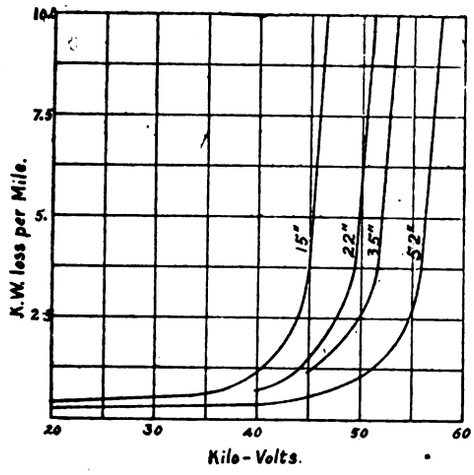


represent firemen, and the broken lines the time of working of the different engineers. For instance, starting at 1 a.m., it will be seen that one fireman is on duty until 11 a.m. At 8 a.m. another fireman starts to work, and is on duty until 6 p.m. Another fireman starts working at 3 p.m., and leaves off at 1 a.m., while one coal passer, whose labour is charged to the boiler-room as a generating cost, starts to work at 7 a.m. and leaves off at 6 p.m. Similarly the diagram shows one engineer coming on duty at 2 p.m. and working until midnight, another works from 4 p.m. until 4 a.m., while a third works from 4 a.m. until 4 p.m. Three other diagrams are given, showing respectively the time of operating the different engines the individual generators, and the boilers. With these charts before him, the station manager can see at a glance for any hour of the day the number of men who are on duty and the quantity of plant in operation, thus facilitating a suitable distribution of the work, due regard being had to the output of the station at different hours, and to such considerations as the cleaning and repairing required of station men operating a small plant.

Alternating-Current Power Transmission.—In the course of a series of papers on "Alternating-Current Working," contributed by Mr. W. B. Gump to the *Western Electrician* of Chicago, the author remarks, in regard to the question of frequency, that the cost of apparatus,

Digitized by Google

especially transformers, is often the determining factor, high-frequency transformers costing less than those for low frequency. Against this lower cost, however, he places the increased inductance both of the apparatus and transmission line, and also the increase of wattless currents due to inductance, causing a greater loss in the generator, line, and apparatus used, and the decreased efficiency of generators, synchronous motor, and rotaries, on high frequencies. The author observes that in practice a frequency of 60 cycles is seldom exceeded for power installations; 40 cycles is often used for a mixed load both for local use and on large distribution systems; and for power alone he recommends 25 to 30 cycles. On the question of voltage the author makes the general statement that the voltage for transmission within an immediate locality should be as high as safety will permit. On long transmission lines where step-up transformers are used the line pressure should be as high as the physical conditions of the case allow, together with due consideration for human life. For voltages up to 15,000 the difficulties of insulation are not serious, but when 20,000 is reached they begin to multiply greatly. As the voltage increases the leakage increases very rapidly. We reproduce a diagram given in illustration of this, a series of tests having been made upon an experimental transmission line. The curves are plotted between values of line voltage and line loss. The figures on the respective curves denote the distance between wires in inches. It will be seen that the loss decreases for a given voltage as the distance between wires is increased, a marked difference being shown between the first and last curve.



Junior Institution of Engineers.—Visits of this institution were recently paid to the Chelsea generating station of the Underground Electric Railways Company of London, Lots-road, Chelsea, and to the adjoining London County Council's pumping station. At the former the general manager, Mr. J. R. Chapman, and the resident engineer, Mr. J. W. Towle, were present, and the visitors were enabled to make a complete examination of the work so far as it had advanced. The station will supply current for working the trains of the District Railway from Whitechapel to the various western and southern termini, Richmond, Wimbledon, Hounslow, Ealing, etc., also the tube trains of the Baker-street and Waterloo Railway, the Great Northern, Piccadilly, and Brompton Railway, and the Charing Cross, Euston, and Hampstead Railway. The initial equipment of these lines will be about 150 trains. The station is designed for 10 units of 5,500 kw. each and one unit of 2,500 kw. The output of the station will be three phase, 33⅓ cycles, 11,000 volts, and will be distributed at this potential to 23 sub-stations. Attention may be called to the group system which has been followed throughout in both the mechanical and electrical installation—*i.e.*, eight boilers are grouped to one turbo-generator. These boilers have their own feed pump, and the generator supplies its own section of 'bus bar. No attempt is made to cross-connect the steam-piping of the different groups except at the east end of the building, where three groups are brought together in one small auxiliary header for supplying exciters, air-compressors, house pump, etc. The station is designed for turbines, and illustrates the reduction in floor area which can be secured with this type of engine as against the reciprocating type. At the London County Council pumping station Mr. H. M. Rounthwaite received the members. There are here four horizontal gas-engines, having each two 18½in. cylinders, with 2ft. stroke, both coupled to one crank (cylinders at opposite ends). On each crankshaft is a 7ft. 6in. rope pulley grooved for eight 1¼in. ropes, and these ropes lead down to similar pulleys of 6ft. 5in. diameter on the four centrifugal pumps. The pumps have suction and delivery pipes 23in. diameter, and impellers of 66in. diameter. These engines each indicate about 200 h.p., at about 150 revolutions per minute, and the pumps each throw about 44 tons per minute. There are also four similar engines, 18½in. cylinders, 2ft. 6in. stroke, 7ft. 6in. rope pulleys on crankshafts, grooved for 10 1¼in. ropes and 10ft. 4in. similar pulleys on pumps. The pumps have 32in. pipes and 72in. impellers. These engines each indicate about 240 h.p at about 160 revolutions per minute, and the pumps each throw about 85 tons per minute. The 200-h.p. engines pump from the low-level sewer, and the other engines from the higher level Counties Creek sewer. The whole plant works only during rainy weather, and pumps storm water only into the Thames. The average number of hours per annum during which it will be required to run is estimated at 60 or 70, though, of course, in exceptionally wet years it may be that the machinery will run as long as 100 hours.

The Telephone Service.—It will be remembered that at the conference of metropolitan local authorities held at the Guildhall on May 18, resolutions were passed to the effect that it would be inexpedient for the Government to acquire the undertaking of the National Telephone Company on any other terms than those set out in the agreement between the Postmaster-General and the company, dated Nov. 18, 1901, and also that the conference was of opinion that before any agreement was entered into with the National Telephone Company for the purchase of their system within the London telephone area, the terms of the proposed arrangement should be submitted for the consideration of the local authorities within that area. Copies of these resolutions were sent to the Postmaster-General, and on Tuesday the conference met to consider his reply, Mr. A. C. Morton presiding. Lord Stanley's latter, dated June 6, stated that he had carefully considered the resolutions, and, as the delegates no doubt were aware, the agreement with the National Telephone, dated Nov. 18, 1901, had reference solely to the London area, whereas the proposals which had been recently under discussion had reference to the acquisition of the company's exchange system in the whole of the United Kingdom at some date in the near future. He was in doubt as to the exact intention of the first resolution of the conference, but if it was suggested that the company's system, not only in London, but in the whole of the United Kingdom, should now be acquired on the terms agreed upon for the London system in 1911, he thought that the company could hardly be expected to accept at the present time, when they were at liberty to

Digitized by Google

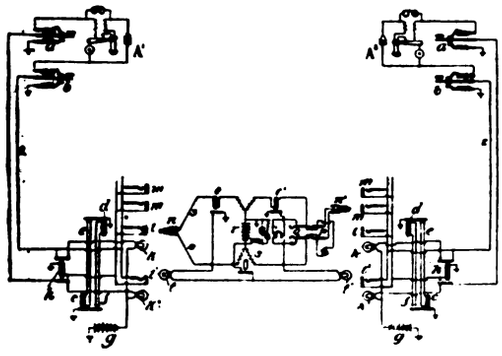
carry on their business for seven years more, the terms which they accepted as applicable on the termination of their license, when their plant could no longer be used by them for its present purpose. Lord Stanley expressed his conviction that the acquisition by the Government of the whole telephone system of the country in the near future, provided that the price to be paid was reasonable, would be more for the public advantage, and it was because he held this opinion that he consented to enter upon the negotiations now in progress. With regard to the second resolution passed by the conference, Lord Stanley had already stated in Parliament that full opportunity would be given for the consideration by Parliament of any agreement between the Government and the National Telephone Company which might be proposed. He did not see his way to promise that an agreement, which would be applicable to the whole of the United Kingdom, should be directly submitted to local authorities representing only a limited part of the country. In his view, the proper method of charge for an exchange service was that which was recommended by the Select Committee of 1898, under which the payments of the subscribers were fixed in proportion to their user. The message-rate system offered by the Post Office fulfilled this requirement, and its advantages had been proved by its acceptance by more than 90 per cent. of the subscribers to the Post Office London system. The Chairman remarked that the further expressions of Lord Stanley in the House of Commons on June 16 made it clear that nothing more would be done during the present session, and under the circumstances the best thing for the conference to do would be to inform him that the resolution of May 18 was intended to apply only to the London telephone area. This was agreed to, and it was then decided to adjourn the conference until the matter again came before Parliament.

The Electrical Congress.—We are informed that a number of national electrical bodies have already arranged to co-operate in the International Electrical Congress of St. Louis. In America, a number of these co-operating bodies are to hold simultaneous conventions in St. Louis during the congress week, and to hold joint sessions with specified sections of the congress on definitely appointed days. Other bodies are not going so far as to hold simultaneous conventions and joint sessions, but have accepted invitations to send delegates to the congress. Invitations to send delegates have been sent to 30 national electrical and scientific bodies all over the world. The following bodies have already promised to hold simultaneous conventions and joint sessions: the American Institute of Electrical Engineers, the American Electro-Chemical Society, the American Physical Society, the International Association of Municipal Electricians, and the American Electrotherapeutic Association. The following bodies have promised to send delegates to the congress: the National Electric Light Association and the Association of Edison Illuminating Companies. In Europe, the following bodies have promised to send delegates to the congress: the Société Internationale des Electriciens and the Sweizerischer Elektrotechnischer Verein. It is expected that the Institution of Electrical Engineers of Great Britain and the Elektrotechnischer Verein of Berlin will also send delegates. It is hoped that other European national electrical bodies will also co-operate. The delegates accredited to the congress from various co-operating bodies are not expected to be called upon to vote upon any questions of national importance. All matters concerning units, standards, etc., will lie within the province of the chamber of government delegates. All delegates of the co-operating bodies are invited to read papers before any section of the congress they select. Such papers will be printed in the congress *Transactions* as being offered by the delegate on behalf of the co-operating body. The paper and discussion thereon will subsequently be offered by the congress to the co-operating body for incorporation in its own *Transactions* if desired. In response to invitation, the following foreign Governments have appointed delegates: Switzerland (Profs. Ferdinand Weber and Francois Louis Schule), Norway and Sweden (Prof. G. Arrhenius), India (Mr. J. C. Shields), and Mexico (Mr. Rafael R. Arizpe). The appointments from Great Britain, France, Germany, Austria-Hungary, United States, Belgium, Italy, Denmark, Spain, Portugal, Australia, Japan, China, Brazil, Chili, and Peru have not yet been made. It is stated that appointments are being made. Up to the 23rd ult. 1,776 adhesions to the congress had been received. Programmes of Sections A, B, C, D, and E have already been published, and we now give those for Sections F and G. Of the former, which deals with electric transportation, Dr. Louis Duncan is the chairman, and Mr. A. H. Armstrong the secretary. The papers, with their authors, are as follows: "Theory of Compensated Repulsion Motor," by Ernst Danielson; "Electrification of British Railways," by Philip Dawson; "Single-Phase Electric Railways," by Herr F. J. Eichberg; "Alternating *v.* Direct-Current Traction," by Prof. Dr. F. Niethammer; "The Puffer Machine in Railway Service and its most suitable control," by Prof. Dr. Rasch; "The Electrification of Steam Lines," by A. H. Armstrong; "Electric Railways," by B. J. Arnold; "General Review of Railway Work," by Louis Duncan; "The Storage Battery in Electric Railway Service," by J. B. Entz; subject to be announced, C. O. Mailloux; "Some Qualifications of Electric Railway Equipment for Trunk Lines," by E. H. McHenry; "Braking High-Speed Trains," by R. A. Parke; "Electric Railways," by W. B. Potter; "The History and Development of the Electric Railway," by F. J. Sprague; "Notes on the Electrical Equipment of the Wilkesbarre and Hazleton Railway Company," by L. B. Stillwell; "Central-Station Economics and Operation," by H. G. Stott; and "Equipping the Central Terminal," by W. J. Wilgus. Section G, which deals with electric communication, will have as chairman Mr. F. W. Jones, and as secretary Mr. B. Gherardi. The papers and authors are as follows: "Electric Communications in Spain," by Senor Don Julio Cevera Baviera; "The Present State of Wireless Telegraphy, by Dr. J. A. Fleming, F.R.S.; "A New Danger to Lead-Covered Aerial Telephone Cables," by John Hesketh; "Simultaneous Telegraphy and Telephony," by Herr Joseph Hollos; "Telephony and Telegraphy in Japan," by Saitaro Oi; "System for Producing Continuous Electrical Oscillations," by V. Poulsen; "Questions Connected with Rates and Management in a Telephone Exchange," by G. de la Touanne; "Printing Telegraph Systems," by J. C. Barclay; "Rapid Telegraphy," by Dr. Albert C. Crehore; "Wireless Telegraph Receivers," by Dr. Lee De Forest; "Rapid Telegraphy," by Patrick P. Delany; "Telephony," by Hammond V. Hayes; "The Telephone Problem in Large Cities," by Franz J. Dommerque; "Wireless Telegraphy," by Reginald A. Fessenden; "Features of Two-Strand Common Battery Systems," by J. C. Kelsey; "Problem: Automatic *v.* Manual Telephone Exchange," by Kempster B. Miller; "Telephony," by F. A. Pickernell; "Printing Telegraphy," by Louis M. Potts; "Military Use of the Telephone, Telegraph, and Cable," by Colonel Samuel Reber; "Electrolysis of Underground Conductors," by Prof. George F. Sever; "Economical Features in Modern Telephone Engineering," by L. W. Stanton; and "The Theory of Wireless Telegraphy," by John Stone Stone. Contributors are again reminded that efforts are being made to secure as many as possible of the promised papers

Digitized by Google

in advance, so that copies may be printed for circulation at the congress.

Cord Circuit for St. Petersburg Exchange.—The Russian capital is soon to have a new up-to-date telephone exchange, to be installed by the Western Electric Company of Chicago. The board will be of the divided-multiple type, as the exchange is to have accommodation for 40,000 subscribers, but the divided-multiple arrangement will probably not be utilised until an adequate number of subscribers is obtained. A feature to be introduced in this system is the circuit recently patented by Mr. E. H. Smythe, of Freeport, Ill., of which some details are given in the *Western Electrician*, of Chicago. The board will be divided into two sections (A and B) of 20,000 lines each. Every subscriber's line will have an answering jack in each section of the board, but half the lines will have multiple jacks in one section and half in the other, the subscribers' apparatus being provided with two buttons corresponding to the sections at the exchange. Hitherto in arrangements of this character no means of retracting a signal were provided if the subscriber depressed the wrong button, but Mr. Smythe's invention obviates this difficulty. The general arrangement of the circuits is the same as before, but some changes have been made, which allow of the subscriber, having given the wrong signal, to extinguish the lamp at the exchange, and call the right section without waiting for the operator to come in on the line.



The circuits of two lines to the exchange are shown in the accompanying diagram. The circuits and apparatus are arranged so that a subscriber, having caused the display of his line signal at one section by operating one of his signal keys, may, by operating another, efface the signal first displayed, and bring about the display of his signal at another section. Replacing the telephone on the hook acts to efface whichever signal is at the time displayed. These results are obtained by including a relay in each side of the line, which, when actuated in response to the control of its associated key at the sub-station operates to close a locking circuit for itself controlled by the telephone switch at the sub-station, to light a lamp at one of the switchboards, and to short-circuit or shunt the relay included in the other side of the line. The telephone station A^1 is provided with the usual apparatus. On depressing either key the limb to which it belongs is closed to ground, opening the line at the sub-station. On being released (the receiver being off the hook), the key completes the circuit before opening the ground connection. The relays *c* and *d* are provided in the circuits of limbs of the line. It will be observed that when either of the relays is operated, the corresponding circuit will be closed and grounded by the armature of the relay that is operated. If the subscriber at station A^1 desires to communicate with the subscriber at station A^2, both subscribers belonging to section A, the former, having removed the receiver from the hook, will depress his key, *a*, which will operate the line signal *k* at section A. The armature of relay *c* will be attracted and will close the contacts of the circuit *f* to ground. The key *a* having been released, and the receiver being removed from the switch, the circuit of limb (1) will be transferred from ground at station A^1, through station A^1 by the telephone switch to limb (2), thence to the central office, and thence to one of the wires of the circuit *f*, to the armature of relay *c*, and thence to ground—that is to say, the first impulse of the battery *g* will be to ground. Keys *a* and *b* are so constructed that one circuit to ground is completed before the other is broken, in order to prevent any intermission of the flow of current through the line relay which has been actuated. It should be remarked that the resistance of the circuit, including individual-line signal, k^1, is so great as to prevent the operation of the signal. The line signal *k* at section A, however, is included in a local circuit formed by the closing of the armature of relay *c*. Hence line signal *k* will be disclosed immediately on depressing key *a*, and will remain disclosed as long as the receiver at station A^1 is removed from the switch, or until the call is answered by inserting the plug in the answering jack, *l*, or until key *b* is pressed to display signal k^1. When relay *c* draws up its armature in completing circuit *f*, it short-circuits relay *d*, so that it is not excited by current flowing in limb (2) of the line. When plug, *n*, is inserted in response to the disclosure of signal *k*, current from battery *r* is directed over wire (4) through relay *h*, thus cutting off the signalling apparatus of the line, and the armature of repeating coil, *s*, is closed, connecting battery with the circuit of supervisory signals, $t\,t^1$. Lamp *t*, however, will not light, since its circuit will be open at the contact of relay *o*, the battery circuit being closed through the relay *o*, over limb (2), through sub-station A^1, and back over limb (1). Supervisory signal lamp t^1 will, however, be included in a circuit extending from the free pole of the battery *r*, through the armature and front contact of the repeating coil and the armature and back contact of relay *o* to earth. The lamp t^1 will then light. The operator, ascertaining that subscriber A^2 is called for, proceeds to test the line, make the connection, and signal subscriber A^2 in the usual manner. Assuming now that subscriber A^1 desires to be connected with a subscriber belonging to the other section (B), the former, having removed the receiver, will depress key *b*, thus completing circuit from battery through signal *k* and limb (2) to ground at the signal key *b*. The resistance of the circuit is so great that signal *k* will not be operated, but the relay *d* will be operated and the circuit *e* closed. The closure of this circuit completes the circuit of signal lamp k^1 directly to earth, and illuminates it and closes a short-circuit of relay *c* in the other limb of the line, thus rendering it inert to current returning over limb (1) of the line when key *b* is released. Releasing key *b* completes the locking circuit of relay *d* through both limbs of the line and the switches at sub-station A^1 to earth at the central office by way of conductor *e* controlled in contacts of relay *d*. The continued display of signal k^1 after the momentary depression of key *b* is thus effected. If, after the signal k^1 has been displayed, the subscriber should desire for any reason to withdraw signal k^1 and display signal *k* in its stead, he has merely to press key *a*. The depression of key *a* opens the locking circuit of relay *d*, permitting the relay to release its armature, upon which relay *c* is actuated to light lamp *k* and short-circuit relay *d*, as already described, or, if the subscriber, after having caused the display of one of the signals, desires to withdraw the call, he may do so by replacing his receiver on the hook, which breaks the locking circuit operating to effect the continued display of the signal.

WIRELESS TELEGRAPHY.

BY R. G. BLAINE, M.E., A.M.I.C.E., ETC.

(Continued from page 58.)

The Braun-Siemens and Halske System.—In this, one of the most successful and, in some respects, most novel and interesting of the Continental systems, a closed circuit is employed, in which oscillations are set up, which may by a proper choice of self-induction and capacity, be adjusted to a determined period. An open resonator is employed, and this transmitter sends out waves of a known length, the circuit of the receiver being tuned to respond better to this length of wave than any other. The inventor of the system is Prof. Braun, of Strasburg, and it has been

DR. BRAUN.

acquired by the great German electrical firm of Siemens and Halske. Symmetry is observed in both the transmitting and receiving apparatus, and—unlike some other systems—there is not any earth connection, this fact causing the apparatus to be very little affected by atmospheric disturbances. The transmitting circuit is shown diagrammatically in Fig. 62, where J is the inductor, S the spark gap at the secondary terminals of same, L the self-induction, C the capacities. It is not difficult to show that in a circuit of this kind the discharge sets up oscillations of which the periodic time T is, according to Lord Kelvin =

$$\frac{2\pi\sqrt{LC}}{\sqrt{1-\frac{CR^2}{4L}}}$$

and, if $\frac{CR^2}{4L}$ is small in comparison with 1, as is usually the case; then $T = 2\pi\sqrt{LC}$, very nearly; or $L = \frac{T^2}{4\pi^2 C^2}$ which enables the self-induction to be calculated if the

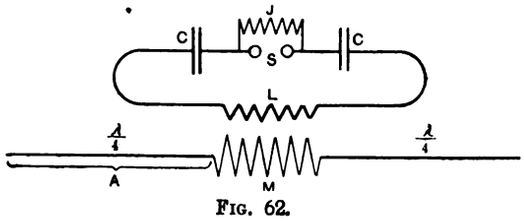

FIG. 62.

other quantities are known; or C to be obtained if L and T are determined. If λ is the wave-length since $\frac{\lambda}{T} = V$ (the velocity of light); then $T = \frac{\lambda}{3\times10^{10}}$ where λ and the velocity are in centimetres and centimetres per second respectively.

Referring to Fig. 62, the oscillations of the closed circuit of the resonator are forced upon the secondary coil M, and in order that the intensity may be a maximum an amount of wire or capacity must be added to each end of M to put this secondary circuit in resonance with the closed circuit. The length of this secondary circuit on each side of M is found to be $\frac{\lambda}{4}$ if the best results are to be obtained. One of these lengths includes the aerial; the other may be coiled into a coil (but shortened owing to increased self-induction), or it may be replaced by a suitable capacity. The receiver circuit, shown in Fig. 63, is very similar to that of the transmitter, but the action is reversed, the etheric oscillations being received in the open circuit, A, and forced on the closed circuit, which in this case affects through M the circuit containing the coherer, relay, and indicator or Morse machine.

Referring more fully to the apparatus, the inductor or induction coil (Fig. 64) differs considerably from others in use, since the aim is not so much the high pressure necessary to produce sparks across the gap as a large current output. This is attained by the use of a special iron core, a larger primary and a shorter and thicker secondary

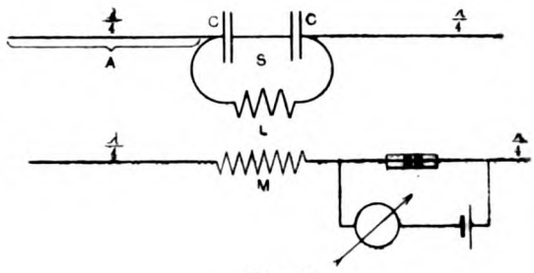

FIG. 63.

winding than is usually employed. The insulation is also double that of the ordinary coil, and hence it will work well even in damp places. The primary has three terminals, giving different lengths of primary for different interruptors. With these inductors large capacities can be charged in a short time. The interruptor is of the "Wehnelt" electrolytic type. This electrolytic break, brought out in 1899, employs for one electrode a lead plate immersed in dilute acid, and a platinum wire passing through the bottom of a porcelain tube for the other. In a circuit containing inductance the current passes intermittently from the platinum to the lead, the interruptions being very rapid, as high as several thousand per second in some cases, and being to some extent variable, depending on the amount of protrusion of the platinum wire. It has been found to work best at a potential difference of 60 to

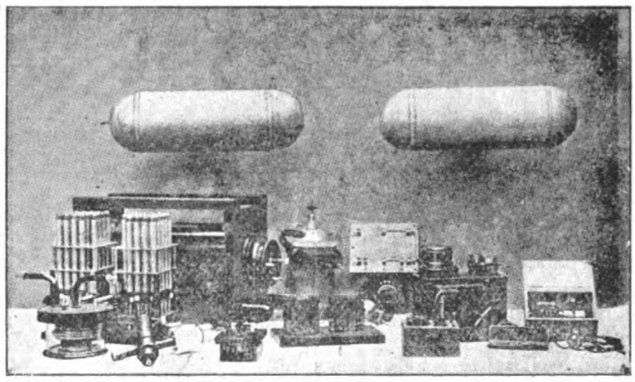

FIG. 64.

80 volts, and gives usually from 100 to 2,000 interruptions per second. The interruptions are not, however, under such exact control as in some of the other breaks already referred to. In the form shown the upper part of the platinum pole above the surface of the liquid is also protected from acid vapours by the porcelain tube. A peculiar form of Morse key is necessary to take the heavy currents—as much as 50 amperes. A magnetic blow-out is fitted, which quickly extinguishes the spark. The Leyden jar capacities are of elongated cylindrical form. To provide a capacity to balance the aerial in the secondary wire of the transmitter, round-ended cylinders are employed.

Digitized by Google

Two of these are shown suspended above the apparatus in Fig. 64, where the inductor with three projecting terminals is seen to the left, with the Leyden jar capacities in front of it, and the transformer, M, already referred to, in front of that again. The interrupter is distinguishable (in the centre) by the peculiar inclined hoop with which it is surrounded, the remaining apparatus being the Morse key, etc.

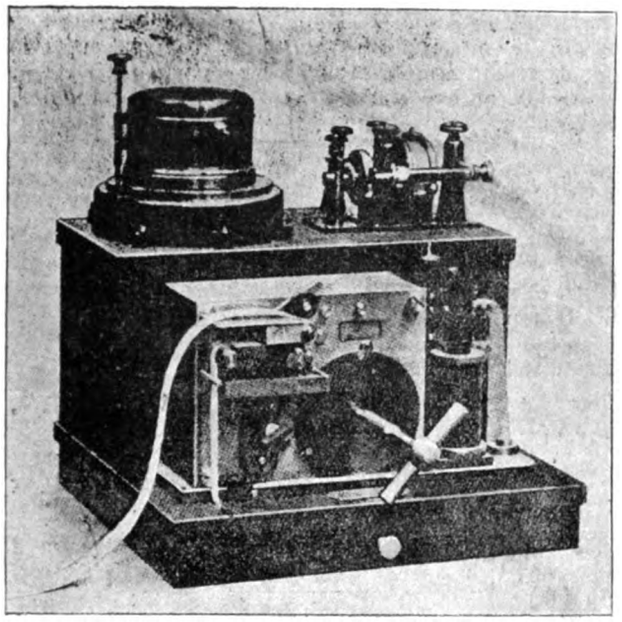

FIG. 65.—Receiving Apparatus.

The receiving apparatus is shown separately in Fig. 65, the coherer consisting of an ebonite tube containing hardened steel particles of a uniform size between two polished steel electrodes. It is known that a coherer becomes magnetic by use, and whilst this to a certain extent aids the coherer in the performance of its functions, too much magnetisation renders it unreliable. To obtain the requisite amount of magnetisation, and to render the coherer adjustable as to sensitiveness, a permanent ring magnet is fitted to it. Where a *record* is not wanted, where syntonising is not of importance, and for great distances, a telephone receiver with microphonic attachment is employed. The microphone consists of a steel disc pressed against a carbon or steel point. By means of a screw the pressure of the disc on the point, and hence the sensitiveness of the receiver, can be varied at will. The microphone telephone and dry cell are shown in Fig. 66. A view of the installation in one of the principal stations in Berlin fitted up with the apparatus of this system is shown in Fig. 67.

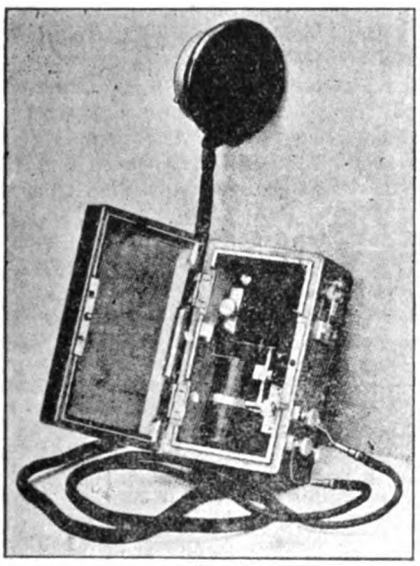

FIG. 66.

Wireless telegraphy is destined to play a very important part in modern warfare, and the field equipment shown in Figs. 68 and 69 is interesting in this regard as showing what is being done in the German army.

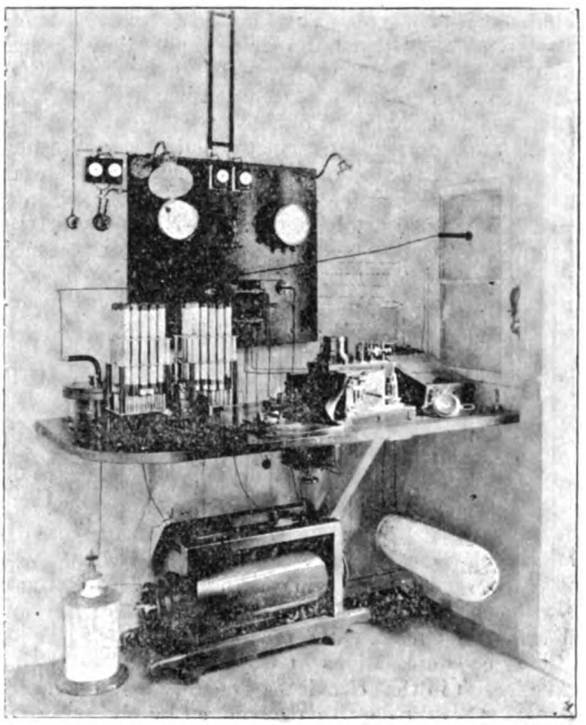

FIG. 67.—Braun-Siemens and Halske System. Interior of the "Hochbahn" Station, Berlin.

The New Wave Meter (*Arco-Rendal System*).—Early in the history of wireless experiments inventors set to work to improve the effects due to electric waves, using the well-known laws of electric resonance. But new difficulties accompanied the new improvements, definite dimensions and dispositions were necessary to suit each wave-length. Hence the difficulty of tuning, say, a dozen stations so as to properly respond to the same wave-length, though their installations may be quite different. The wave-meter, therefore, becomes a necessity.

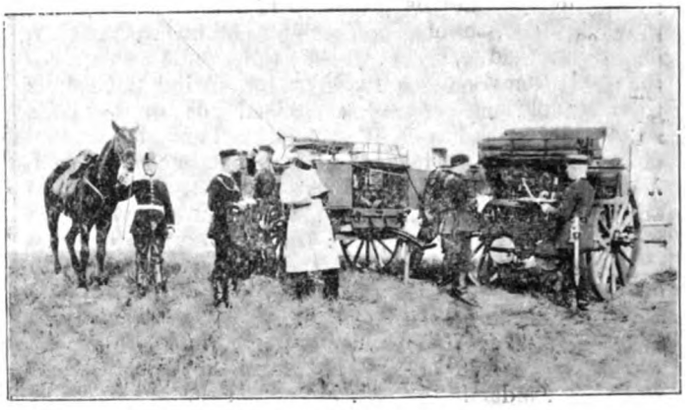

FIG. 68.—German Army Wireless Field Equipment.

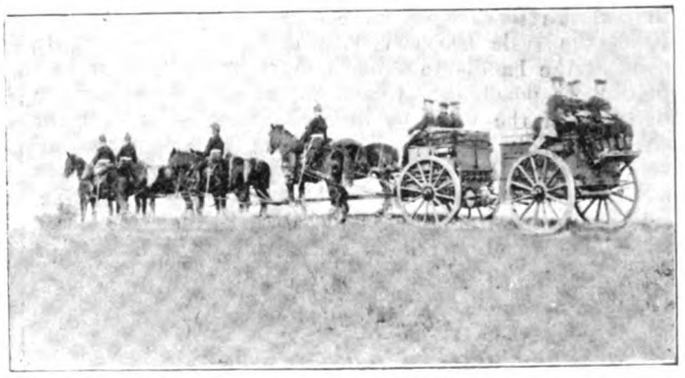

FIG. 69.—German Army Wireless Field Equipment.—Detachment on the March.

Digitized by Google

The principle of this apparatus consists in establishing a normal open or closed system, in which the inductance and capacity are both variable. The variations are indicated on a scale, and the scale may be calibrated to directly indicate lengths of waves. The simplest form consists of a coil covered with one layer of wire. The number of turns put in circuit can be easily regulated by a slider, which allows the short-circuit of a certain number of turns. The principle was initiated by Count Arco and developed by Mr. Rendal. The apparatus is attached to the system to be indicated, and the number of windings put in circuit changed until the coil comes into resonance, which is recognised by observing the maximum rise of potential at the terminals of the coil, which in turn may be measured by the length of spark obtainable. The number of turns in circuit being noted, the wave length is found from a curve. This apparatus, though simple, is not exact enough for up-to-date technical work.

The precision of a measuring operation depends essentially upon the damping conditions as well of the wave meter as of the oscillating circuit to be indicated. The measuring coil shows less damping than a long conductor, because it emits less of its oscillating energy, but more than a closed circuit. The closed circuit form of the apparatus was originated by Herr Dönitz and Dr. Franke, and is patented by the Braun, Siemens, and Halske Company. A closed circuit has a very definite time period, as already noticed, this time period being defined by the inductance and capacity of the circuit. By modifying one or other of these the electric oscillations of the circuit, and through it the wave length in that circuit can be altered. In the coil apparatus the resonance was determined by observing the highest potential, as shown by the spark length. In the closed circuit apparatus, however, resonance is recognised by observing the current intensity by means of a hot-wire ampere meter. The circuit is composed of an inductance and a plate condenser, the latter being adjustable. It is composed of two series of metallic half-round plates equidistant from each other, one of the series being fixed, the other movable round a spindle. If the spindle is turned, the movable plates come into the spaces between the fixed ones. The half circle described by the handle which turns the plates is divided into 180deg. By putting the handle to, say, 160deg., a capacity is obtained four times as large as that when the handle is at 40deg. Thus by variation of the capacity only, it is possible to obtain a range from λ to 2λ. The inductance can also be altered, three coils are added to every apparatus, so that the ratio between the inductances may be as $\frac{1}{4} : 1 : 4$. To every one of these coils a special scale is fixed, from which the wave length can be read directly, for lengths varying between 140m. and 1,120m. (460ft. and 3,674ft.). In using the apparatus it is placed near the circuit to be indicated, in such a way that the field of the latter excites the coil of the wave-meter inductively. Having chosen the most suitable of the three coils, the capacity is varied till the ampere-meter shows maximum current. The wave-meter is then in perfect resonance with the circuit under examination. From the scale the wave-length is read directly. By shifting the handle to the left or right of the resonance point it is possible to form an idea of the clearness or damping of the wave by observing whether the current changes rapidly or slowly. To permit the measurement of the natural oscillations of a simple aerial, auxiliary coils are added. Accuracy within 1 or $1\frac{1}{2}$ per cent. is obtainable, and the instrument is portable and convenient. These particulars have been kindly furnished by the *Gesellschaft für drahtlose Telegraphie*, Berlin.

(To be continued.)

VOLTAGE DROP IN THREE-PHASE SYSTEMS.

BY W. W. WOOD.

A quick and practical method of calculating the voltage drop in three-phase conductors is seldom given in articles on three-phase work, most writers confining themselves to a discussion as to the relative merits of various systems of distribution. Such a method, however, is constantly required in the preparation of estimates for power installations where motors have to be supplied at moderate distances from the distributing centre. In these systems it is seldom necessary to consider the capacity or inductive effect of the cables themselves, but what is required is a rule for finding the lost volts and power with any given current density in the conductors.

For continuous currents the want has been long supplied by the well-known approximate law that five volts are lost per 100 yards of transmission (200 yards single conductor) with a current density of 1,000 amperes per square inch. This also gives the percentage loss of power in transmission, which is the ratio $\frac{\text{lost volts}}{\text{voltage of supply}} \times 100$.

A law of similar form for three-phase work is the easiest both to remember and apply, and can be readily deduced from first principles as follows. Considering the case of a balanced three-phase system,

Let R ohms be the resistance of each lead;
Let C amperes be the current in each lead;
Then the loss per conductor $= C^2 R$.
The total loss = loss in three conductors $= 3 C^2 R$.

Now, the power input to the line $= C \cdot V_1 \cos \phi \sqrt{3}$, where V_1 = voltage of supply, $\cos \phi$ = power factor, or cosine of angle of lag of current behind voltage; also if V_2 = the voltage at the distant end of the line, the power output $= C V_2 \cos \phi \sqrt{3}$.

(*Note.*—V_1 and V_2 are the virtual volts measured between any two conductors. C the virtual amperes per conductor.)

Now, since the power input = power output + the loss in transmission, we get the equation

$$C V_1 \cos \phi \sqrt{3} = C V_2 \cos \phi \sqrt{3} + 3 C^2 R$$

$$C \cos \phi \sqrt{3} (V_1 - V_2) = 3 C^2 R$$

$$\text{Lost volts} = V_1 - V_2 = \frac{C^2 R 3}{C \cos \phi \sqrt{3}} = \frac{C R \sqrt{3}}{\cos \phi}.$$

When $\cos \phi$ = approximately ·87, the expression

$$\frac{C R \sqrt{3}}{\cos \phi} = 2 C R,$$

which is the voltage drop which there would be on a similar continuous-current system.

We thus get the rule that "with a power factor of approximately 87 per cent., 5 volts are lost per 100 yards of transmission (three-core) when the current density in the conductors is 1,000 amperes per square inch." It is, moreover, obvious from the above expression that the loss is inversely proportional to the power factor, and directly proportional to the current density; thus, with power factor of 1, the drop = 4·33 volts per 100 yards of transmission, density 1,000 amperes per square inch. At 500 amperes density the lost volts would be halved.

The percentage loss of power (or with direct currents) is simply $\frac{\text{lost volts}}{\text{volts of supply}} \times 100$.

This is proved as follows:

$$\text{Percentage loss of power} = \frac{\text{watts lost}}{\text{watts input}} \times 100$$

$$= \frac{3 C^2 R}{C V_1 \cos \phi \sqrt{3}} \times 100$$

$$= \frac{C R \sqrt{3}}{V_1 \cos \phi} \times 100$$

$$= \frac{\frac{C R \sqrt{3}}{\cos \phi}}{V_1} \times 100$$

$$= \frac{\text{lost volts}}{\text{volts of supply}} \times 100.$$

The above rule is equally applicable whether the system is star or mesh connected, since only the current per line conductor and voltage between these conductors has been considered.

INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

Ninth Annual Convention.

On Thursday the convention was resumed at Nottingham, where the Mayor (Councillor A. PAGE, J.P.) extended a warm welcome to the members. Alderman Sir JOHN TURNEY, the chairman of the Electric Lighting Committee, also welcomed the association to Nottingham. He said that a good deal was made of the exceedingly cheap supplies of electrical energy given from Corporation station, but he was not quite sure that it might not be a good policy to slightly increase the selling price and to make more profit.

Mr. WILMSHURST thanked the two previous speakers on behalf of the association for their kind welcome. Nottingham was to be congratulated on the unbroken continuity of the management of its electrical undertakings. The gentlemen in charge of these were highly esteemed by the members of the association, and he knew of no municipal undertaking more remarkable for reliable, economical, and excellent management than the electrical department of the city of Nottingham.

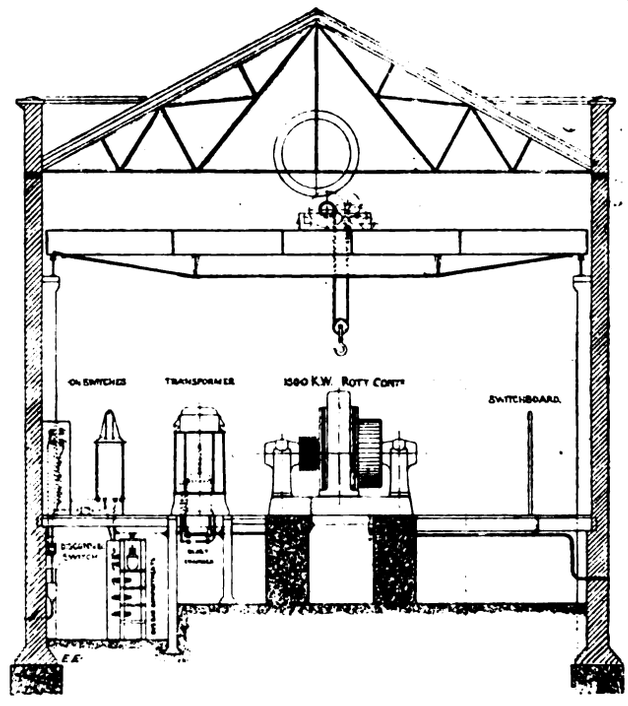
Mr. S. L. PEARCE then read his paper on "Polyphase Sub-Stations," the opening portion of which appeared in our last issue.

Polyphase Sub-Stations: Their Equipment and Working.

BY S. L. PEARCE, CHIEF ELECTRICAL ENGINEER, MANCHESTER.

(Continued from page 53.)

Fig. 4 show another typical general arrangement for a large capacity rotary sub-station, very similar to the foregoing.



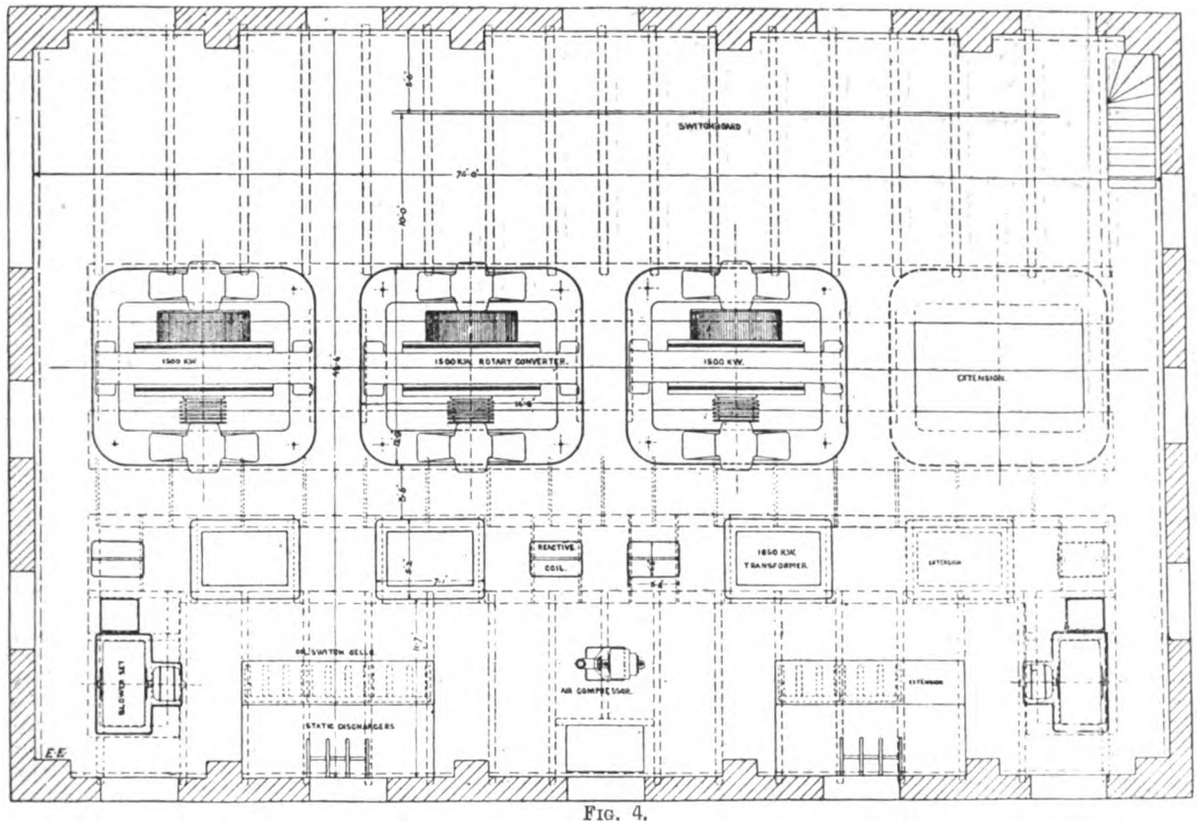


FIG. 4.

The main high-tension 'bus bars are, however, placed below ground floor, single three-phase transformers are employed, and the cooling of the latter is effected by means of a separately driven blower set. Reactance coils are used in conjunction with the rotaries for traction purposes to obtain the compounding effect; these reactance coils would be replaced by induction regulators (which enable the impressed E.M.F. on the rotary slip-rings, and consequently the direct-current voltage, to be varied at will), if the machines were used for lighting purposes. The low-tension switchgear is similar in all respects to that of an ordinary direct-current station. In the case of a purely traction system the switchboard proper would only contain one pole, the remaining switches and 'bus bars being placed in the vicinity of the machines themselves in the same way that equaliser switches and bars are now placed in many large direct-current traction stations. The negative pole of the rotary being directly connected to the negative bar and earth without introducing any switch, the secondary of the transformer is permanently earthed through the machine, and forms a safeguard in case the high-tension winding of the transformer should break down on the secondary. This arrangement very much simplifies the switchgear, as the equaliser switch is mounted on the rotary itself, the equaliser bar and negative bar being placed in a pit close below the rotaries, leaving only the positive single-pole switch and 'bus bar to be placed behind the switchboard proper. It is preferable that the high-tension transformers in sub-stations of this type should be placed in the same room as the rotary converters themselves. The great advantage of having them continually under observation, in the author's opinion, outweighs the argument that the safest position for the high-tension apparatus of this nature is under lock and key. It is quite possible for a serious fire to start without the fact being known when the transformers are contained in a separate compartment, whereas when they are readily seen, they can be cut off from the line on the slightest indication of a fault.

Fig. 5 show the general lay-out of one of the sub-stations for the Liverpool and Southport line of the Lancashire and Yorkshire Railway Company, the equipment consists of four 600-kw. six-phase rotaries operating at 25 cycles, and producing direct current at 600 to 650 volts. Three single-phase transformers of 200 kw. capacity connected up in "mesh" are employed for each unit. They are of the air blast cooled type, the rotaries are arranged down one side of the building, with the corresponding static transformers down the other side—the switchboard being situated at one end. The high and low tension switchboards are placed together in one long line. Beneath the high-tension portion of the gallery is a fireproof chamber, in which the oil switches and other high-tension gear are placed, the whole being worked mechanically by operating levers from the panels above. All instruments are low tension, being worked through transformers.

Examples of Motor Generator Equipments.—Figs. 6 and 7 show two typical equipments for the sub-stations of the Manchester Corporation. The Polygon is one of 10 stations, the general design in each case being the same, although the size and arrangement are modified to suit local conditions. The building is divided into two bays, the larger containing at the one end the traction motor generators, also the separate high and low tension switchboards. At the other end are placed similarly the lighting motor generators and balancing sets, and the corresponding high and low tension switchboards. In the second bay provision is made for extension sets. Each traction set consists of a synchronous motor operating direct at 6,500 volts, and coupled to a 220-kw. continuous current compound wound generator, the exciting current for the motor field being obtained from an exciter mounted on an extension of the shaft, or as an alternative from the lighting 'bus bars. Each lighting set similarly consists of a synchronous motor direct coupled to a 220-kw. continuous-current shunt-wound generator to give 420 to 430 volts across the outers of a three-wire system, and they are also so arranged as to give 210 volts on either side of the middle wire. The exciting current for the motor is taken from the terminals of the low-tension generator, or as an alternative from the lighting 'bus bars. The balancing sets, one of which is provided in each sub-station, consist of a 125-kw. three-phase induction motor direct coupled to two 52-kw. continuous-current shunt-wound generators, placed one at each end of the motor shaft, supplying current at about 205 volts, as balancers on the lighting system, or for starting or exciting the traction motor-generators. Two high-tension switchboards are placed on galleries, one at each end of the main bay, and two low-tension switchboards are placed on galleries along the front side of the main bay, both being used for traction and lighting respectively. The high-tension boards are arranged in three tiers. On the lower or basement level are placed the sealing and dividing boxes, into which are brought the high-tension feeders from the power station, the spark-gaps, feeder and motor duplex fuses, field-regulating resistances, liquid starters, and stator transformers for the induction motors. On the main platform are placed the switch panels with all the necessary instruments. The third or upper gallery carries the duplicate high-tension 'bus bars and selector switches. Means are provided for interconnecting the 'bus bars of the two boards, so that traction sets can be run from lighting feeders and *vice versâ*. The low-tension boards are arranged in two tiers, the various resistances and starters being placed on the basement level, but, as in the case of the high-tension boards, they are operated from the main gallery. The high-tension cable work in the station is almost entirely three-core, armoured throughout, cleated to the floor, and run in earthenware pipes through the beds where necessary, suitable tail-end boxes being provided at the terminals.

The second type of sub-station is represented by "Oldham-road," which is typical of the second 10 stations. With the exception of two, all are arranged for both lighting and traction. Each station is arranged in one bay, with the high-tension switchboards on one side and the low-tension on the opposite side, the machines being placed in pairs down the centre, provision being left at one end for considerable extensions. The equipment, consisting of synchronous and induction-motor generators, is very similar to the previous type, their outputs varying from 250 kw. to 104 kw. The low-tension generators of each set are, however, compound wound, and are, therefore, available for either lighting or traction purposes. A saving in spare plant and space is thereby affected, as against the use of separate sets for each purpose. The main switchboards are placed on galleries 9ft. above floor level. The high-tension board controls the incoming and outgoing feeders and the synchronous motors, and is provided with two sets of 'bus bars, to which the lighting and traction feeders are respectively connected. But as each motor is provided with a change-over switch, and can therefore be run off either set of bars, the arrangement is practically equivalent to a "duplicate set." Frequently lighting and traction sets are run off the same 'bus bars, and the varying load of the latter has not been found to interfere with a steady voltage being obtained from the former. This would appear to raise the question as to whether separate lighting and traction 'bus bars are really a necessity. Under the main gallery and on the floor level are placed the various resistances, starters, and feeder chargers, the latter consisting of three separate water tanks, forming a non-inductive resistance. This arrangement has been found preferable in every way to the choking coil or separate motor-generator type. A cable subway runs the whole length of the building on each side, and receives the high and low tension cables as they come in from the streets, and also carries the machine leads. The latter are single conductor cables throughout, drawn through Doulton ducts between the machines and the subways.

Static Transformer Equipments (Beyer Peacock's).—Fig. 8 shows the general arrangement and diagram of connections of a sub-station recently equipped for Beyer, Peacock, and Co., Gorton, Manchester. The transformers are of 60 kw. capacity, six of these being banked together in "mesh" to form two groups of 180 kw. each. The ratio of voltage is 6,500-220. They are of the natural ventilation type. The switchboard is of the multi-frame order, and has panels controlling the two high-tension feeders, two high-tension transformer panels, and two low-tension distributing panels. The current is metered

on the primary side of the transformers, and a recorder is fixed on the low-tension panels reading direct in horse-powers. Provision is made for extension, the above instalment representing rather more than one-third of the capacity of the works. The efficiency of the transformers has been guaranteed for 98·5 per cent. at full load, with a drop of not more than 4 per cent. when working on any power factor.

WORKING OF SUB-STATIONS.—STARTING UP.

(*a*) *Rotary Converters.*—There are three possible ways of starting up a rotary converter: (1) From the alternating-current side by switching it straight on to the supply lines. This method was adopted and as far as the author knows is still in vogue on the Central London Railway system, and on the Liverpool and Southport line, in the case of the first rotary to be started up each day. It is necessary to have a field-splitting switch in order that the shunt winding may be opened before starting, otherwise they would break down owing to the excessive E.M.F. induced at the moment of closing the alternating-current main switch. Further, if the rotary be compound-wound, the series field windings must be open-circuited. All switches on the direct-current side must be left open before switching the rotary on to the line. By reason of the hysteresis lag in the poles, and in a lesser degree due to the eddy currents set up, the rotary will start as soon as the alternating-current switch is closed, and will immediately run up to synchronous speed. As soon as synchronism is attained, the field-splitting switch and direct-current field switch can be closed. With self-exciting sets care must be taken to see that the latter is closed as the machine is building up on the right polarity, which can be done by closely observing the direct-current voltmeter. If this is not done, the polarity on the direct-current side of the rotary will be reversed. The rotary will now be running in synchronism with the main generators, and can be paralleled on the low-tension 'bus bars in the usual way. Although this method may be unavoidable in some cases, it has serious disadvantages, chiefly on account of the large current at low power factor which it draws from the supply lines, and the possibility of the rotary building up on the wrong polarity. For traction work this method may be employed, but not for lighting purposes. (2) Starting up from the direct-current side is a far simpler operation, and presents no difficulties of operation, and can usually be followed in most instances where a supply of direct current in the sub-station is available. In the case of the Central London Railway this method was always adopted for all sets after the first. For lighting systems the starting current required for large units might occasion a heavy drop on the distributing mains, and it will become necessary either to provide an induction motor-generator set to supply the necessary direct current, or, better still, the following third method may be usefully employed. (3) This consists in coupling on to an extension of the rotary shaft a small three-phase, low-pressure induction motor, the capacity of which should be approximately one-tenth of the full load output of the rotary. By means of this starting motor the whole set may be brought up to synchronous speed, the alternating-current and direct-current fields adjusted, and then synchronising the alternating-current side of the rotary on to the line, afterwards cutting out the starting auxiliary unit.

(*b*) The starting up of synchronous motor sets presents no difficulties, and is usually from the direct-current 'bus bars, and synchronising on the alternating-current side in the usual manner. It is, however, absolutely necessary that provision be made in every sub-station for the plant to be started up from the alternating-current side in the event of a possible shut-down of the lighting or traction systems. Such means are to hand in the employment of induction motor sets, which in lighting sub-stations are frequently coupled up to the balancers. Their value in this respect forms an additional reason, in addition to those previously set forth, why a combination of induction and synchronous motor sets is desirable. If battery power is available this will provide the alternative direct-current supply, but it rarely happens that battery stations and polyphase sub-stations are combined.

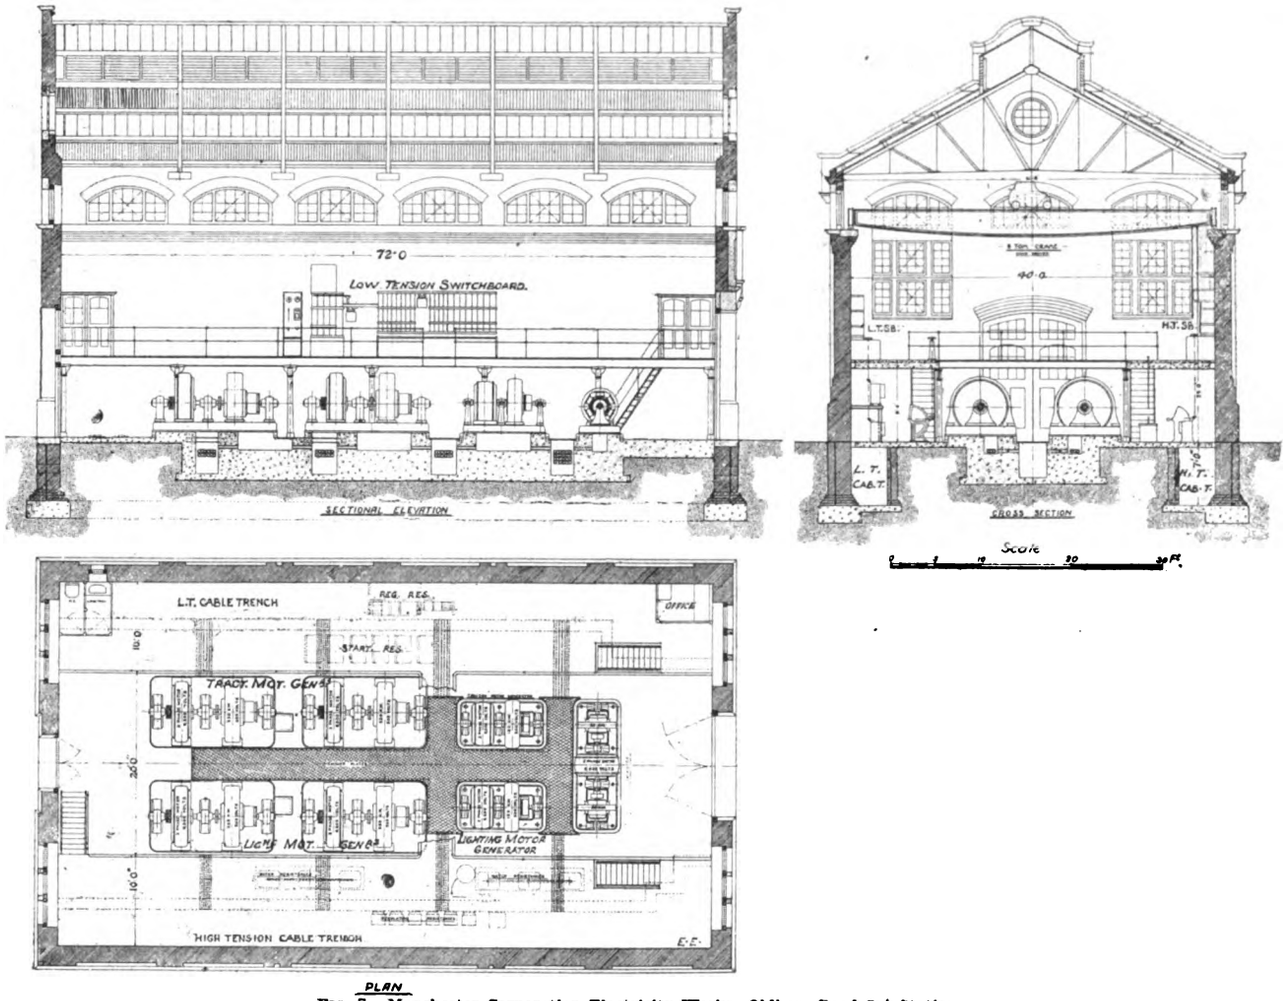

FIG. 7.—Manchester Corporation Electricity Works Oldham Road Sub-Station.

(*c*) A method of starting up applicable to both rotaries and synchronous motor-generators is shown in Fig. 9, and is a slight modification of the first method described for the starting up of the former. The compensator shown reduces the primary voltage to one half. The double-throw oil-switch, which is fitted with an overload device, is thrown down on to the bottom contacts. Half voltage is thus impressed on the rotary or synchronous motor, and the field switch being left open, the machine runs up on an induced field. When full speed is attained, and the field built up in the right direction, the field switch is closed, the oil switch is thrown over on to the top contacts—*i.e.*, on to the full-voltage bars—and the starting high-tension oil switch is withdrawn. The motor-generator with induction motor is the simplest of all types of sub-station equipment to start up. With long feeders it is desirable that the pressure on the feeders should be applied gradually

Digitized by Google

to the stator of the induction motor, as any throw-up in the voltage due to the capacity of the feeder at the moment of switching in might break down the insulation of the motor. A suitable design of three-phase stator starter to be used for the purpose is shown in Fig. 10. It consists of three coils arranged in a triangle, and carefully insulated by cylinders of mica. Each coil is provided with an adjustable core consisting of a large number of iron sheets 1-50in. thick. The three iron cores are attached to a round disc, which is held by a three-armed cast-iron holder, through the middle of which runs a screw, and the three iron cores can thereby be raised and lowered. The three coils are switched in series with the corresponding phases of the motor which is to be started up. Before switching in, the iron cores are lowered into the coil, so that on first switching in only a small current goes into the stator of the motor. The cores are then gradually raised out of the coils, the inductive resistance being thereby gradually lessened, and finally the coils are short-circuited. A water resistance or other suitable form of starter is inserted between the slip-rings of the rotor, and short-circuited as soon as the set is up to speed, when the machine can be paralleled in the usual manner on the direct-current side. On account of the heavy rotor cables with large units, it is desirable, to avoid expense, that the rotor starter should be placed as near the machine as possible, and a

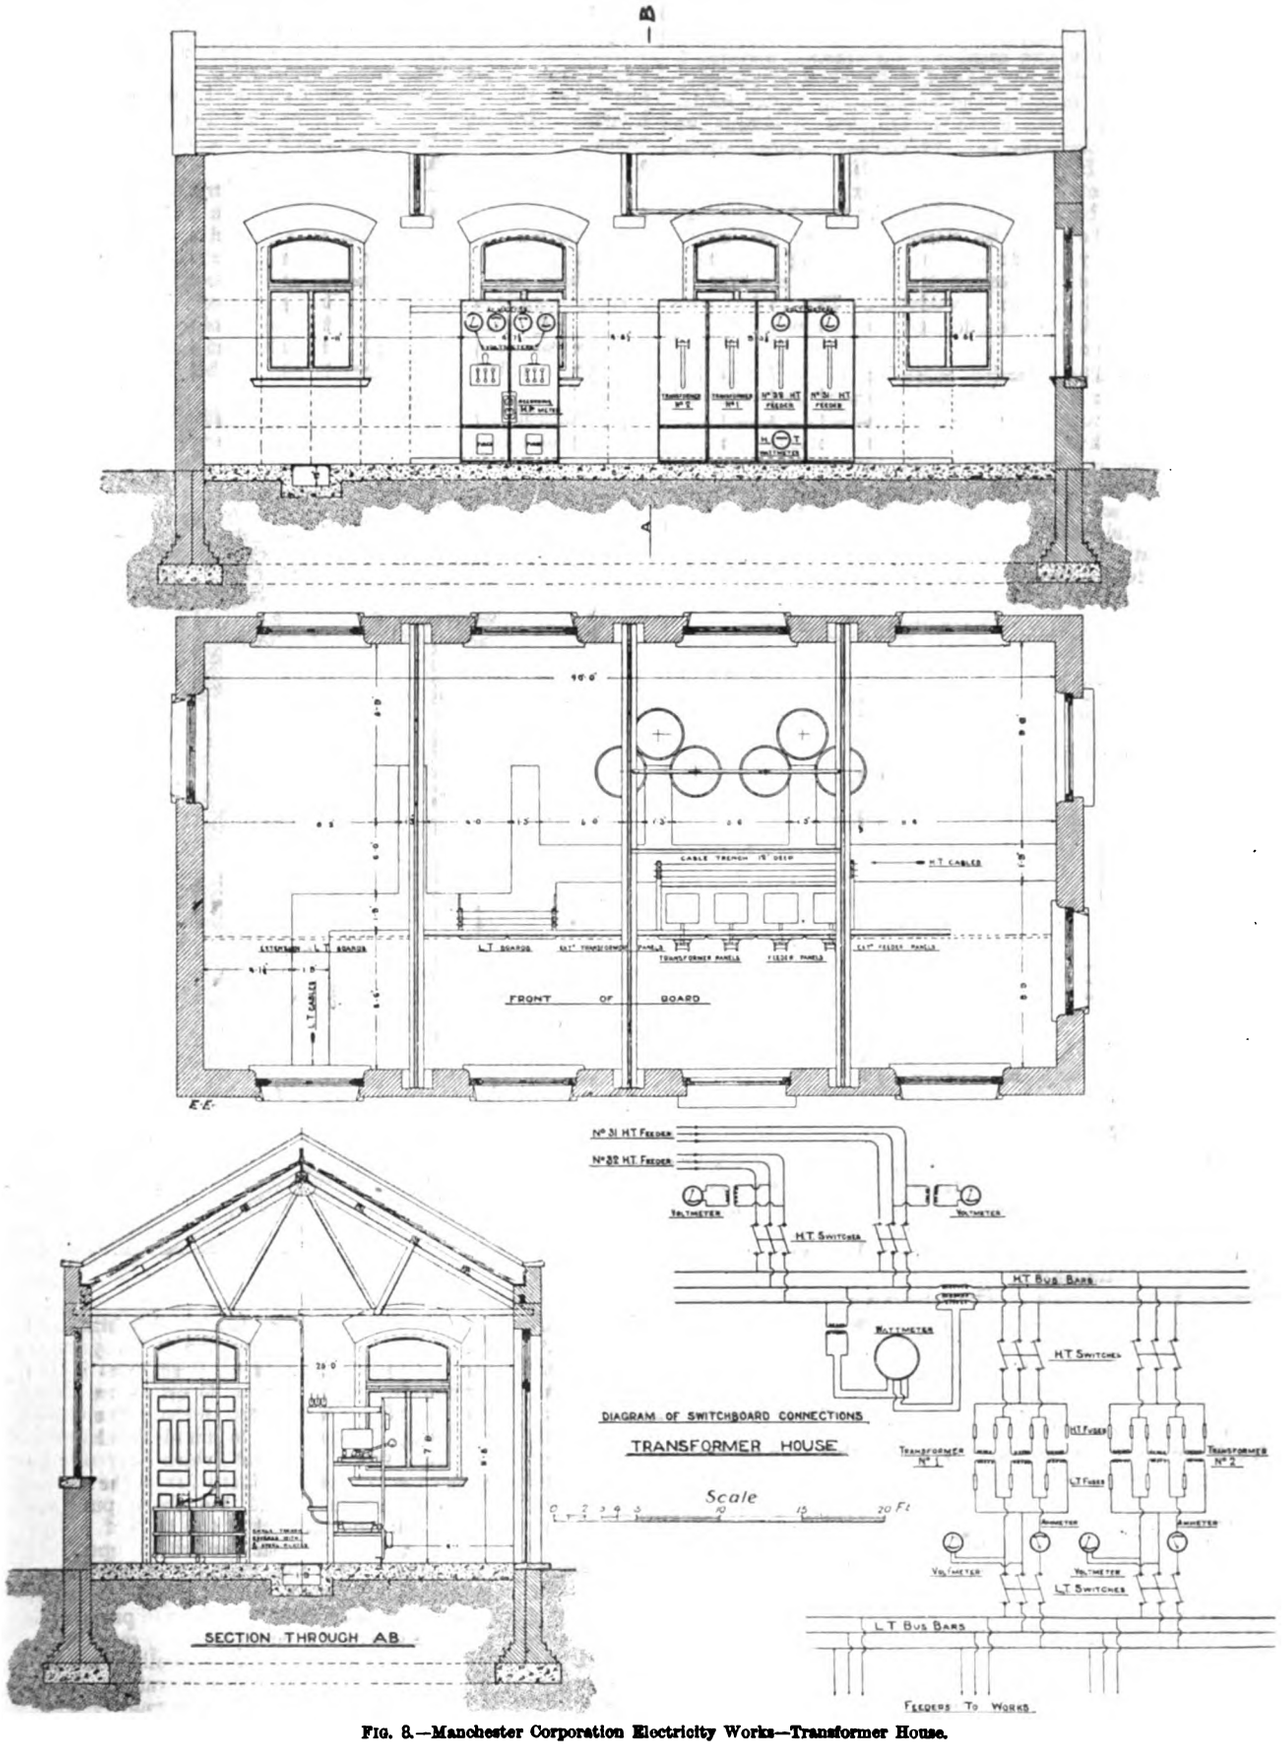

FIG. 8.—Manchester Corporation Electricity Works—Transformer House.

Digitized by Google

convenient arrangement is to operate it by means of bevel gearing from the front of the switchboard platform.

Exciting.—Rotaries are invariably self-excited for obvious reasons. There is one strong disadvantage, however, with this method, consequent on the possibility of the rotary reversing whilst under load. This happened on two or three occasions on the Central London Railway system, and is a possibility to be reckoned with. If the rotaries are excited from the 'bus bars, then a battery connected across the bars becomes imperative. For synchronous sets employed on traction circuits, a separate exciter mounted on the end of the shaft is probably the best method of exciting the high-tension motor fields. Although it occupies extra space, it provides an alternative method of excitation from the lighting 'bus bars where a mixed system is supplied. In any case it is desirable that the excitation for the traction sets should be independent of the lighting system, and this can best be obtained by the use of a separate exciter, or a method to be described later on under "Balancing." For synchronous sets on lighting networks, excitation from the direct-current terminals or low-tension 'bus bars will probably be found sufficient. The author considers that the question of excitation is of importance, and should be well considered.

(*d*) *Balancing.*—The effective balancing of a three-wire lighting network from sub-stations can be secured by the use of an induction motor coupled to two generators giving about half the pressure across the outers, the whole combination forming an auxiliary set for the supply of direct current necessary to start the larger synchronous units. It is, however, desirable that additional means of balancing should be provided, either by the use of double-wound armatures with the synchronous sets or other methods. An alternative arrangement has been used extensively in the Manchester sub-stations, and emanates

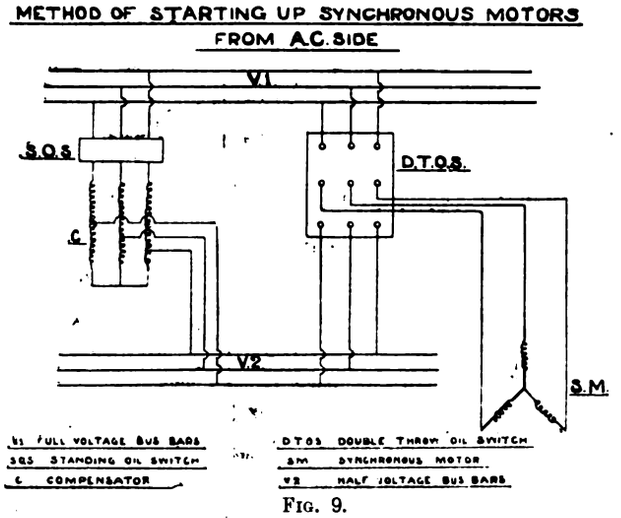

FIG. 9.

from the Allgemeine Company. This apparatus is essentially a choking coil, the ends of which are connected up by means of two slip-rings to the armature of the continuous-current dynamo. The slip-rings are connected up to the armature at such points that a normal alternating current at the frequency corresponding to the number of pole-pieces and the revolutions is circulating in the equaliser. The middle wire of the system is connected up to the middle point of the choking coil. If the load on each side of the two net halves is unequal, the overload on one will pass through the middle wire into the respective side of the equaliser, and through the slip-ring belonging to it back into the armature. This method also provides another supply for exciting current, and if all the synchronous plant in each sub-station is so arranged, it is evident that each set will be self-excited. An out-of-balance current up to 25 per cent. can be dealt with under this arrangement without the difference in voltage exceeding 2½ per cent. of the mean voltage.

(*e*) *Hunting.*—To ensure satisfactory parallel running and immunity from what is known as "hunting," it is necessary that every detail of the system should be very carefully considered. Troubles from this source are almost entirely associated with rotary equipments. If the frequency of the supply system be not uniform—that is, if the variations in the velocity of the main generators during one revolution exceed a definite and certain limit—the rotary converters tend to follow, and vary in accordance with the power-house generators. If these variations occur rapidly, it is impossible for the converters to keep in step, and "hunting" ensues. But this trouble can be set up independently of the power-house engines. Oscillations may be set up from a variety of causes within the rotaries themselves, which if not checked will spread over the whole system. It is necessary, therefore, in the first place, to provide suitably but not too well-governed engines in the power-house; and secondly, to attach special devices to the rotaries themselves to check any oscillations that may be set up. For this purpose "damping coils" are used, which usually take the form of copper plates which bridge over the space between the pole tips. The eddy currents produced in the latter tend to restrain or counteract the distortion of the magnetic field due to the armature oscillations. This tendency to instability of rotaries, however inappreciable for traction work, has, in this country at any rate in the past, placed them at a disadvantage for lighting work. With synchronous machines the author has never experienced any trouble from this source, and given suitable engines at the power-house, there should be no possibility of hunting. The armature reaction of the high-tension motor is considerable, the fields being excited at a constant pressure, and independent of the feeder pressure.

(*f*) *Synchronising.*—It is of greater importance that the machine should be as nearly as possible in phase than at the same voltage. A synchroniser so arranged as to indicate the relative speeds of the incoming machine and those already on the load will be found a useful and time-saving device, and may be combined with the ordinary method of voltmeter and lamps. By the adoption of this type of synchroniser the machine can be synchronised in the shortest possible time, and with the smallest interchange of current between the various machines.

(*g*) *General Conclusions.*—It may be said at once that the majority of sub-stations are required for one or other of the

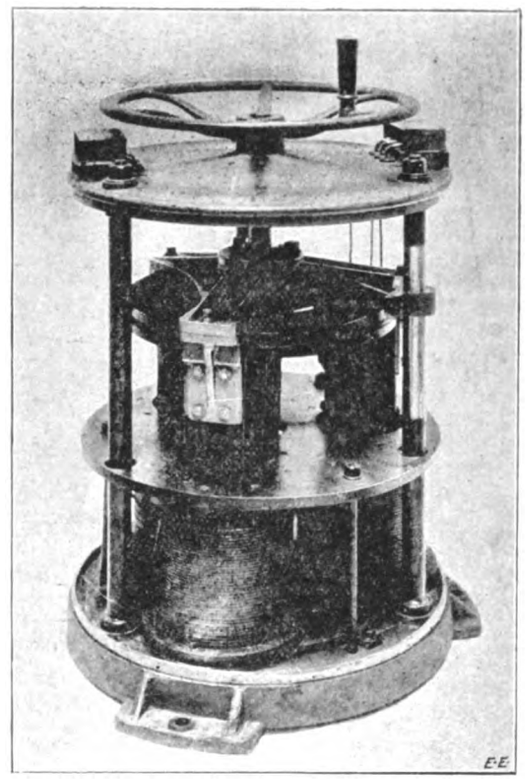

FIG. 10.

following purposes: (1) traction system; (2) mixed lighting and traction systems; (3) direct-current lighting and power systems. For the first of these very strong reasons must exist if the claims of the rotary converter operating at 25 cycles are overlooked. They are at least 5 per cent. more efficient than either of the other equipments, their ability to stand considerable overloads, and the high power factor at which they can be operated, outweigh the disadvantages pointed out in the earlier part of this paper. For the second of the above purposes lighting considerations will probably settle the type of equipment, and for this synchronous motor-generators operating at 50 cycles appear to best fulfil the majority of conditions required—viz., ease of regulation of direct-current pressure, satisfactory parallel running, little or no variations in pressure—in short, they are not so sensitive as rotaries, and they can also be worked at an equally high power factor. It is possible that the disadvantages of the rotary are sometimes exaggerated. Their large use in the States and increasing use in this country point to the fact that under special circumstances their adoption may be deemed warranted. The third class is the one in which, perhaps, most difficulty will be experienced in deciding on the respective merits of synchronous *v.* induction motors. As mentioned before, the drawback to the latter is the fact that the current is always a lagging current, and the smaller sizes have a relatively low power factor. There is also a gain of 1 to 2 per cent. in efficiency in favour of the synchronous type, to

Digitized by Google

balance which may be placed the extra complications in switchgear. For units of 500 kw. and over the author considers that either type might be usefully employed, the increased cost of the induction type being balanced by the increased cost of switchgear with the synchronous type. For units of less than the above output a combination of both types has worked with advantage, the leading currents of the one compensating for the lagging currents of the other, while the induction motors provide the necessary means of starting up the sub-station from the high-tension side in the event of failure on the direct-current side of the system.

In conclusion, the author would take this opportunity of expressing his thanks to those representatives of the British Thomson-Houston Company, the British Westinghouse Company, the Electrical Company, and Dick, Kerr, and Co. who have kindly placed data at his disposal.

Discussion.

Mr. Ruthven Murray, of Willesden, opened the discussion, and expressed the thanks due to the author for treating such important subjects at great length. In such matters one was apt to draw conclusions from one's own practice; and in this respect he (the speaker) proposed to follow the author's example. He was surprised to see the old fable, that rotary converters were not satisfactory, was still quoted. He had used them at Willesden on the electric lighting circuit for the last 12 months without the slightest trouble. There might be cases in which the two-phase system was advantageous, but it lowered the output of the rotary converters. He had found it advantageous to connect up the primary windings of the transformers on the mesh system and the secondary windings as a star. He then obtained any regulation required by means of cutting in or out coils in the secondary windings. With respect to the working of rotary converters at 50 frequency, this had been done on the Isle of Thanet tramways system for some years, and the North Metropolitan Tramways Company had adopted the same for their power distribution work. Working with motor-generators, he questioned the advisability of having 10,000-volt stator windings. With such a machine he did not think it good to start up from the high-voltage side. Mr. Ruthven Murray then enlarged on the advantages of the induction motors, and held that the power factor of these was not so disadvantageous as some people held. He pointed out that the tables of cost of the various equipments and the curves of these costs did not agree. He called attention to the importance of the most careful designing of the wiring in high-tension sub-stations, and held that, with the exception of the cable insulation, no combustible material should be used at all.

Mr. S. Z. De Ferranti said that the impression left on him by the paper was that there were too many complicated details in the systems described for them to be adopted as standard practice. There was, he feared, a great tendency to adopt complicated arrangements and to introduce instruments to give readings which frequently were of little use. If equal facilities could be arranged for checking the boiler-room staff, considerable economies might be effected. He, as they knew, believed that the single-phase system would survive as the most fit. If they compared an electric light station to a gasworks, they would be struck by the simplicity of the latter; and in the competition for giving cheap power, simplicity and low first cost must be studied. Since his remarks on the same lines at Huddersfield, four years ago, there had been many advances made in the design of single-phase motors—they were now being used even for railway work on a commercial scale. As regards converters, he thought the mercury lamp type might be the final form.

Mr. C. H. Wordingham, of the Admiralty, also referred to the prejudice which existed against rotary converters. Against this, however, it must be remembered that they were on an average 5 per cent. more efficient than other machinery for converting three-phase current into direct current. The author showed also that their cost per kilowatt was only £3·8 as against £5·5 for the motor-generators. As regards the frequency, he thought a good many approached this question in the wrong direction. They ought first to decide on the equipment to be used, and then fix the frequency to suit their requirements. He would like to ask the author if he found the connection of the centre of the star of the three-phase system on to the zero wire of the three-wire system had any disadvantages. As regards transformers, he was surprised to see a great difference between the cost of a three-phase transformer and of three single-phase transformers to give the same output. He doubted the advisability of connecting heavy feeders direct on to 'bus bars without the interposition of either fuses or circuit breakers.

Mr. Highfield, of the Metropolitan Electrical Supply Company, remarked that, as regards standard frequency, it was a pity the Standardising Committee had not got to work years ago. They had decided to recommend 50 and 25 as the standard. At Newcastle-on-Tyne the power company had adopted 40, and his own company used 60. He thought that reliability should be considered much more than the efficiency. They found, for instance, if the lights went out even for a few minutes in an area where there was a competing supply, a certain number of consumers changed over. In the same way, in such an area, if consumers demanded a direct-current supply, it must be given, and he found they could get ½d. per unit more for the direct current. They could, however, give the alternate-current supply more economically, and did so where there was no competition.

Mr. A. E. Hadley, of the Electrical Company, said that a flexible system was wanted. By adopting 50 frequency they had a larger number of manufacturers to draw their supplies of standard machinery from. He thought, however, that this frequency gave more trouble with the rotaries than a lower one. One point against the motor-generators with asynchronous motors was the noise which they made.

Mr. J. H. Rider, of the London County Council, advocated the induction type of motor for motor-generators as being more simple and reliable. These motors would not give trouble owing to a short-circuit, as did rotary converters. In transmitting three-phase current to be used as direct current, they should make the link between the two as strong as possible. With rotary converters, a slight hitch in the generating station or a short-circuit on the mains lasting only a few seconds might shut down the whole system. In starting up again, all the low-tension mains at the sub stations had to be disconnected, and he found that it took about 10 minutes to get the cars started up again on the London County Council system. He believed in replacing fuses with automatic oil-break switches arranged to go at overloads. He did not see why the author advocated earthing the centre of the star through a resistance—his machines would well stand a short-circuit current without any damage. He thought that the synchronoscope for paralleling alternators had removed all trouble which existed in this work. As regards cables, he advocated specifying for 12,500-volt cables for a working pressure of 10 000 volts. The extra insulation did not cost much, and it guarded against breakdown. He had never found the rise of voltage when switching on to exceed twice the normal voltage, and the cables with the above proportion would well stand this.

Mr. S. L. Pearce, in reply, said that there was only limited experience with the use of rotary converters for lighting circuits—there was, he thought, with a frequency of 50 a tendency to instability. There was no difficulty in putting the full pressure of the high-voltage supply direct on to the stators. The curves of cost were correct for the various equipments, and these did not agree with the table because transformers had been left out of the latter. In reply to Mr. Wordingham, the connection of the zero wire of the three-wire system on to the centre of the star was good. They also coupled together the electric lighting and electric traction omnibus bars with success. The noise of the induction motors was most objectionable, and they were unable to use 50 per cent. of their motor-generators for this reason, as the neighbours objected. He did not agree with Mr. Rider as to the duration of a shut-down if the machine got out of step. They could get their station running in three minutes, and all their sub-stations started up again within seven or eight minutes of the stop. He called attention to the over-all efficiency of from 75 to 76 per cent. between the generating station and a consumer.

The following paper was then read.

Some Notes on the Bristol Electricity Works Fire.

BY H. FARADAY PROCTOR, CITY ELECTRICAL ENGINEER, BRISTOL.

Having been asked by your council to introduce to this meeting the question of the Bristol fire, the author does so with the view of affording an opening for considering the possibilities of electricity works fires in general and the Bristol fire in particular. Since so much has been published in the technical Press and elsewhere, there is little or no scope for originality in the following notes, which at best must be looked upon as a bald statement of facts, but which a few months ago in the hands of an artistic story-teller would have been converted into interesting and sensational matter. A fire occurred at the Temple Back electricity works belonging to the Corporation of Bristol at 5.15 on Wednesday evening, Dec. 23, 1903, resulting in the destruction of the 2,000-volt high-tension "Ferranti" switchgear, and damage to portions of the roof and windows of the engine-room. The machine switchboard, wattmeter switchboard, trunk feeders from the Avonbank electricity works, and the whole of the 44 feeder panels were destroyed, as well as all the cables leading up to them from underground.

It may be well to remind you that at Bristol there are two generating stations—viz., Temple Back (the old), and Avonbank (the new). The Temple Back station, occupying the more central position, is at present used as the distributing centre for the whole of the high-tension energy, the current from Avonbank being delivered to Temple Back through six ·30 square inch, two-conductor, concentric, paper-insulated, lead and steel-tape armoured cables, and from Temple Back the energy is delivered by similar feeder cables (of varying sections) (·1 square inch to ·05 square inch) through 44 feeder panels to about 60 transformer sub-stations in different localities. The only generators that need be considered in connection with this matter are the four 750-kw. to 1,000-kw. steam alternators at Avonbank, all of which were running at about two-thirds of normal full load, and two 400-kw. steam alternators, which were running (at two-thirds of full load) at Temple Back in parallel with the foregoing, the total alternating-current load being 2,700 kw. The remaining plant, whether alternating or direct current, does not affect the subject under consideration. The voltage at the generating station at the time was 2,300, and the periodicity 93 ⁓ per second.

There were present at the Temple Back works at the time of the outbreak Mr. H. H. Couzens (deputy city electrical engineer), the stations' superintendent, mains superintendent, and others, and on the switchboard gallery two charge engineers, an improver, and a switchboard boy. The seat of the trouble was evidently in the panels of the two alternators running at Temple Back (Nos. 8 and 10). A considerable arc started on these, and it is reported that some seconds elapsed before the fuse pots burst and scattered oil, which immediately caught fire, and in turn caused all the other fuse pots to crack and let their oil run out. The handles of the machine and trunk main switches were burnt so rapidly that they could not have been operated even could they have been approached. The flames from the burning oil shot up to the roof 20ft. above the switchboard floor, and the matchboarding on which the slates rested was soon ablaze. Curiously, the amperes output only increased by about 200 for the first two or three minutes; hence the plant at Avonbank was kept running until after the lapse of about eight (?) minutes, when the load having increased by about 800 amperes some of the trunk main fuses at Avonbank gave way, and the station was then shut down. The damage done by fire may be said to have been limited to the high-tension Ferranti switchboards, one of the arc lighting boards, the connecting cables from the switchboards to the machines, and from the switchboards to the mains in the streets; and also, as far as the building is concerned, to damage to the roof, teak window frames, and a portion of the switchboard gallery. A slight amount of damage was also done to the stone window sills and glazed brickwork. The total amount of the claim paid by the insurance company was £8,225.

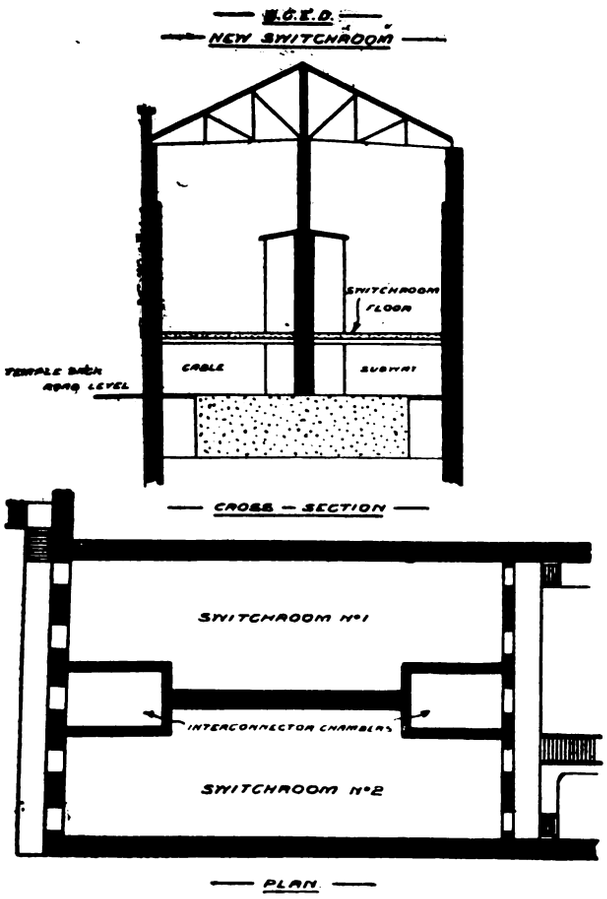
The remains of the old board were very carefully examined, and several consultations have been held to endeavour to ascertain the source of the breakdown, but there is not sufficient evidence to point conclusively to special features constituting the primary cause. It is most improbable that a fault on the external system is to blame, since all of the trunk mains and feeders were protected by fuses, and some minutes after the arc was formed, the ammeters registering the entire output from the Temple Back works were examined and showed a normal current. After the fire it was found that one of the trunk mains, that remained loaded to the last, had fused for a length of about 3ft. to 4ft. in the ground outside the Temple Back works, but as the arc had apparently sufficient resistance to keep the current within the limits of the fuses at the Avonbank end, these did not operate. The fuses at the Temple Back end of this trunk main were not situated where the arcing commenced, and could not, therefore, have been the cause of the same. This cable is ·3 square inch section two-wire concentric, paper-insulated, lead-sheathed, and steel-tape armoured, and was provided with fuses at each end, and probably carried nearly 1,000 amperes before Avonbank was shut down. It would appear that the origin of the trouble is to be found from amongst the following: Firstly, by leakage from the metal work of the board "charged at high pressure" over the surface of the insulators and slate to "earth," or, in other words, to the other pole of the board, in which case it is further possible that this may have been in a measure caused by the presence of moisture or by a crack in one of the insulators due to the jar of operating the switch. Secondly, by the breakdown of one of the cable receivers, in which the cables from the machines to the switchboard are jointed up. In the event of such a fault occurring, however, it is most probable that, owing to the proximity of the two conductors, a "dead short" would have resulted, causing the engine to pull up, the mass of metal being too great to allow of the fault clearing itself, and the machine fuse would have operated, due to the current from other generators. Since the machine in question (No. 8 alternator) did not pull up, and since the fault was not a dead short, as evidenced by the fact that the load on the Avonbank station did not run up to more than about 1,374 amperes—viz., say 200 amperes above the normal load for the time in question—it appears that the fault did not originate at the cable receiver. Thirdly, by the abnormal action of one of the machine fuses, the blowing of the fuse causing an arc and breaking the porcelain pot filled with oil in which the fuse is placed.

Although some engineers who have examined the board since the accident seem to favour the opinion that the improper action of the fuse was the first cause of the trouble, none of the members of the staff hold that view. The fuses were examined by the engineer in charge just a few minutes before the accident, and their temperature was normal. There was not even a full load on the machines corresponding to the switch panels wherein the trouble commenced, and no switching operation was being carried out. Whilst the fault was still "on" and the Avonbank works was still delivering energy to Temple Back, the stop valves of the two running machines at Temple Back were closed and their fields shut off although the machine switches were closed and could not be approached. These machines would thus have formed two dead shorts across the system unless their fuses acted, and since the machines on examination showed no signs of having passed excessive currents, the inference is that these fuses acted in a proper manner and were not the source of trouble. It is very certain, however, that when once the fault commenced the whole of the cause of the spreading of the trouble was attributable to the oil used in the fuse holders and switches, of which there would be about 22 gallons. The fault was very much augmented by the fact that it was impossible to get the Avonbank supply cut off till after the lapse of a few minutes, as all private telephones were rendered useless by induction on the wires, and owing to the great number of calls from consumers, it was impossible to immediately get into telephonic communication over the National Telephone Company's system. It was therefore not until the load at Avonbank became very excessive that those in charge shut down the supply at that station. It was also impossible to get at the switches on the trunk mains from Avonbank owing to the conflagration, though what would have happened at Avonbank had the full load been suddenly and totally removed without explanation or warning is perhaps a matter for speculation; the alternators would probably have run out of phase, and the boilers would certainly have blown off steam. Whether the plant would all have remained in thorough order ready to take up the load as soon as the mains were joined across is difficult to say. Apart from the oil, there was a small amount of wood on the oldest portion of the switchboard floor, which contributed somewhat to the fire. All portions of the flooring, excepting that first installed, were formed of iron chequer plating covered with linoleum, and this withstood the test perfectly, the linoleum within a few feet of the place where the most extreme heat occurred remaining intact. The window frames are of teak, and they were much charred, but these in themselves did not add to the trouble. In the roof the slates were laid upon matchboarding, and this formed one of the most serious features, as the fire reaching this spread rapidly along a considerable length of the engine-room, and necessitated the use of a great amount of water, this water doing a considerable amount of temporary damage to the electrical machinery. The cables contributed largely to the flames, although they were all encased in lead and further protected with steel armouring. The steel armouring, however, was served over with impregnated jute, and this getting soaked with oil was, of course, very inflammable.

In reconstruction it has been considered desirable to avoid: (1) The use of oil in porcelain holders. (2) The use of wood anywhere about the structure of the switchboard floors, unless it is in such form as to be proof against fire. Hardwood blocks set upon a concrete foundation probably form the best and safest description of switchboard flooring, as, whilst it is practicably unburnable, it affords a good insulation from an electrical point

Digitized by Google

of view, and does not appear to be open to the objections that have been found to exist in the case of glass. (3) Cables, although armoured with lead or steel armouring, must be further protected by being either buried or run in metal casings. (4) The roof must have in its construction no wood unless it be thoroughly protected, as in the construction of fireproof doors. Ferranti switchboards of the type whereon the accident occurred have been very generally accepted as being of the most suitable form for use under the particular conditions of the Bristol system, but it seems imperative that boards constructed on this principle should not be built into any external wall of a building, for, although the walls of the generating stations at Bristol are formed of most excellent bricks set in cement, and are 2ft. thick, there is no doubt that with continuous wet weather and strong winds, damp has found its way through, and the back slates supplied with the board afford no



protection. A drawing of the proposed fireproof switchroom is appended hereto.

(*To be continued.*)

PERSONAL.

Mr. Gallinagh has been appointed borough electrical engineer at Limerick.

Mr. Gwillam, late of Messrs. Thompson's Steamship Company, has been appointed assistant engineer at Crewe.

The Barnsley Council have increased the salary of Mr. Colbrun, an assistant of the borough electrical engineer, by 5s. per week.

The Greenock Law and Finance Committee of the Corporation have recommended that the salary of Mr. J. Robertson, burgh electrical engineer, be increased to £350.

Mr. F. J. Hughes, late clerk in charge of H.M. Posts and Telegraphs, Gold Coast Colony, West Africa, and formerly of the Great Western Railway Company telegraph staff, has been appointed H.M. Inspector of Telegraphs, Southern Nigeria.

The Ealing Electricity Supply Committee have granted Mr. J. Douglas Knight, the borough electrical engineer, leave of absence for the purpose of visiting America.

Mr. R. R. Williams, of the Manchester Corporation, has been appointed charge engineer at Bristol.

Mr. J. Tinsley, St. Helens, has been appointed electricity clerk, and Mr. A. Wrigley, Walsall, tramway clerk at Swindon.

Mr. John McMillan, chief electrical engineer to the Falkirk Corporation, on Tuesday received from the assistants and staff at the Corporation electricity works a drawing-room spirit kettle as a marriage gift. The presentation was made by Mr. Wm. Drysdale, A.M.I.E.E., the chief assistant engineer, who spoke of the kindly feelings which existed between the chief and his staff.

The Harrogate Council have increased the salary of Mr. McCourt, mains superintendent, by £15 for 1904 and £15 for 1905, to £180.

ST. PANCRAS ELECTRICITY ACCOUNTS.

The accounts of the St. Pancras electricity department for the year ended March 31, 1904, show a total expenditure on capital account to that date of £460,368. Appended are abstracts of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

FROM LITTLE CAUSES.

If anything goes wrong with electrical work, the most is made of it in the local and even in other papers, hence it is often of advantage to trace to its source the cause of an accident. By accident we do not necessarily allude to personal injuries, but more especially to the stoppage of current. It may be mentioned, however, that personal accidents have happened upon the electrified railways because people have been where they ought not to have been. Many years ago, discussing casually the question of very high pressure currents, Mr. Ferranti remarked they would probably be less liable to personal accident than lower pressure currents, because people would feel certain that an accident would be fatal, and not merely might give a nasty shock, though not necessarily fatal, and thus every care would be taken to remain in a safe place. There is a good deal of truth in that point of "certainty." A wise schoolmaster once said that both with boys and men it was the certainty and not the severity of punishment that kept them from wrongdoing; but probably, like electrical contacts, the certainty of fatality would be much more restraining than the "may survive again and again." Probably upon electrified railways it will be made compulsory to have a guard against accidental contact with a live conductor. The mere fact that accidents have occurred will lead to the recognition that "prevention is better than cure." The other night a simple act caused cessation of lighting in a small district at Rochdale, and as a similar act might occur anywhere attention may be called to it. Some men were laying tramway lines, and, wishing to fence off a certain place, iron stakes were driven between the flags so that a rope fence could be made. One of these stakes happened to be driven through an electric lighting cable laid some foot and a half to two feet below the surface, and immediately there were ructions. The cable fused and a sheet of flame immediately sprang up, while the workmen, under the impression that there was a leakage of gas, commenced to throw buckets of water and a quantity of sand on the flames. The firemen turned out, as smoke could be seen issuing from between the flags for a considerable distance, and the borough electrical engineer (Mr. Atchison) was soon on the spot. On being correctly informed as to what had occurred, he cut the cable where he concluded the fault was, thinking he would clear the fault, but on telephoning to the works he found he was mistaken. He then decided to cut off the whole of the current. One of his assistants opened the feeder box, when an explosion occurred owing to gas having been formed. Fortunately, the assistant (Mr. Wilkinson) was not much injured, though his hair was singed by the flames. Ultimately the current was shut off throughout the town for about twenty minutes until the fault was cleared, and it was found that the feeder cables for a distance of five or six yards were burnt out. This, then, is an accident which is liable to occur in many places unless care is taken to watch all workmen who have to interfere with the streets, and it shows also the necessity of carefully mapping the position of all wires. In this particular case, fortunately, there was little personal injury, but it is quite conceivable that, had the circumstances been different, there might have been what is sometimes called "a calamity." A century hence engineers may look back and wonder why with the engineers at the beginning of the twentieth century simple precautions were not taken to avoid these difficulties. It ought, upon the face of it, to be impossible that any ordinary workman should be able to drive an iron stake through an electric cable, and the probability is largely

Digitized by Google

against such a result; but the inevitable comes along, and everybody wonders that it is so. We must congratulate the electrical engineer of Rochdale that the result was no worse, and we trust the accident which has occurred in his system will be noticed, and care taken that no similar accident can occur at any other place.

THE VERBAND DEUTSCHER ELEKTROTECHNIKER.

The report of the annual meeting of the above association from our special correspondent (a portion of which has already appeared in these columns) shows that no endeavour is being spared in Germany to establish the electrical industry on an enduring basis. Much of the work of the Verband is of universal interest. Take, for example, the question of first aid in case of electric shock. Medical practitioners having called into question the efficacy of the instructions hitherto observed, an enquiry is to be held into the matter, the outcome of which will doubtless be a fresh set of rules calculated to ensure better results. Nor are the Verband satisfied that everything possible has been done to protect persons from electric shocks, and statistics are being obtained with a view to the ultimate improvement of the safety rules now in force. It is recognised that it lies in the interests of the electrical industry to reduce the danger from electric shocks to a minimum, and the statistics referred to will no doubt throw valuable light upon the causes to be most guarded against. The question of compulsory wayleaves for transmission lines is also of more than local importance. It will be interesting to have the report of the special committee appointed to consider this matter. Conditions, of course, vary in different countries, and the solution found in Germany might not be acceptable here, although the interests involved are similar. It is suggested that legislation should recognise the principle of compulsory wayleaves for transmission lines over all lands irrespective of ownership, leaving only the amount of compensation to be adjudged in each particular case. If anything, this means that the shortest route for a projected line could be selected and enforced. It is no longer consistent with the requirements of to-day that transmission lines should be practically restricted to public ways, and legislation designed to enforce wayleaves over private and public property, while safeguarding all interests, is no less essential in this country than in Germany to enable the problem of economical distribution to be solved, both in regard to new schemes impossible of success under existing conditions, and the further development of old-established undertakings.

A NEW RULE FOR BELT CALCULATIONS.

BY YRREB.

After a new machine (either electrical or mechanical) has been fixed and the belt attendant summoned to measure for the length and width of band required, one of the greatest difficulties the average belt man has to contend with is as to the width and thickness the band is required to be in order to transmit sufficient energy to obtain the maximum rated output from the new machine. The length is easy enough to measure, but the width and thickness is quite another matter altogether; so that, generally speaking, the only guide the non-technical man has to help him in deciding the width of band he will use is the width of the face of the pulley, or the band guide which is usually supplied with the machine. Then, if by some mistake or other, the pulley supplied with the machine is rather wider than is necessary, the purchaser or employer of the belt man is put to the extra expense of buying an unnecessarily wide band owing to the man's inadequate knowledge of belt tensions or of belt driving generally. On the other hand, should the pulley supplied with the machine be too narrow or too small in diameter for the full or rated amount of work the machine is guaranteed to perform, the man whose duty it is to attend to the banding is being continually called upon to either use some band solution or again tighten up the band every time the machine is being worked up to its rated output. In the case of having to be continually tightening up, the band eventually reaches its breaking strain, and so causes a complete stoppage. This bad practice not only causes an excessive tension on the band, but it very considerably reduces the life of the shafting, loose pulleys, bearings, etc., which causes a loss of time, money, and temper, and is altogether unsatisfactory.

After many years' experience of belt driving and general engineering the writer has found that a good all-round and easily-remembered rule for belt calculations is that 1ft. per minute of belt speed per inch width of belt is safely equal to transmitting one watt of electrical energy. So that if we multiply the band speed in feet per minute by the width in inches, the result will be the total energy in watts or (dividing by 1,000) in kilowatts that the band can be safely relied upon to transmit without any undue tension being brought upon any part of the band or excessive friction on any part of the machinery. It must be strictly understood that this data only applies to single leather belting or woven belt of equal thickness. If a light double leather band be employed, then 25 per cent. more energy may be calculated upon, or for a heavy double leather band as much as 60 per cent. more may be added. The great advantage in adopting this rule is that it fixes a constant for working tensions, so that the working tension becomes directly proportional to the width in inches, the constant being 44·24lb. full per inch width of belt. Therefore if it is required to know what is the difference in the pull of the tight side over the slack side of any belt, all we have to do is to divide the total output of the machine measured in watts by the velocity of the belt measured in feet per minute and multiply the result by 44·24, and the product will be the extra pull in pounds of the tight side over the slack. It also conveys some idea to the average man when he is deciding upon a belt as to what amount of stress is likely to be brought upon the band when being fully worked up to its maximum load, thus obviating all troubles arising from bands being either worked excessively tight or ridiculously slack. The above working tension per inch width of belt is fairly low, being one that any class of banding should stand. It would also tend to increase the life not only of the banding itself, but of all loose pulleys, shafting, bearings, etc.

As this article is written chiefly for non-technical men, perhaps it will not be out of place to briefly explain the meaning of some of the mechanical and electrical terms that will be used in some of the examples about to be taken. "Mechanical energy," or rate of doing work, is always measured in foot-pounds per minute, which means that in the case of raising a weight, if the total weight in pounds be multiplied by the height measured in feet to which the weight will be raised in one minute, the result will give the rate of doing work expressed in foot-pounds per minute, and 33,000 foot-pounds per minute is equal to 1 h.p. For instance, a 1,000lb. weight raised 33ft. in one minute is just equal to 1 h.p., as $1,000 \times 33 = 33,000$ foot-pounds per minute; or one ton weight raised 10ft. in one minute $= 2,240 \times 10 = 22,400$ foot-pounds per minute $= \frac{22,400}{33,000} = \cdot 679$ of 1 h.p. Electrical energy is usually measured in watts; one watt is equal to 44 24 foot-pounds of work per minute, and is also equal to 10,000,000 ergs per second, 746 watts being equal to 1 e.h.p. If we wish to measure the electrical energy in watts we multiply the volts by the amperes; therefore the total output for any dynamo is amperes × volts = watts, or $\frac{\text{amperes} \times \text{volts}}{746}$ = E.H.P. (electrical horse power). Then, turning back to our rule, which teaches us that 1ft. per minute of belt speed per 1in. width of belt is equal to one watt of electrical energy, we find that if we

Digitized by Google

divide the total output (of any dynamo or motor) given in watts by the velocity of the belt measured in feet per minute, the result will give us the width of belt required for that dynamo or motor.

Another item that might be worth while explaining is circumferential speed of pulleys, and velocity or belt speed. To ascertain the circumferential speed of a pulley, we must multiply the diameter of the pulley in inches by 3·1416 (which is a constant usually denoted by π), and then by the number of revolutions per minute at which the pulley runs, and dividing the product by 12 we get the circumferential speed of the pulley in feet per minute. For example, a 12in. diameter pulley runs at 1,000 revolutions per minute; find the circumferential speed of the pulley in feet per minute.

$$\frac{\text{Dia} \times \pi \times \text{revs. per min.}}{12} = \frac{12 \times 3{\cdot}1416 \times 1{,}000}{12}$$

$$= 3{,}142\text{ft. per minute.}$$

The circumferential speed of a 20in. diameter pulley running at 400 revolutions per minute $= \frac{20 \times 3{\cdot}1416 \times 400}{12}$ = 2,094ft. per minute. Now, when calculating the belt velocity or speed of belt in feet per minute, to be correct we must add the thickness of the leather band to the diameter of the pulley and proceed as before But we must remember that there is a percentage of slip and creep going on continually with every belt that is doing work. So that having to consider these small factors when making calculations, somewhat complicates matters and yet does not materially affect the net results one way or the other. In the writer's opinion, therefore, these might be neglected altogether, and consider the circumferential speed of the pulley as being the belt velocity, which will simplify the method considerably without any serious errors arising from doing so.

Then formulating the rule, letting

W = width of belt in inches;
T = driving tension per inch width of belt;
V = velocity of belt in feet per minute; and
F = total driving tension of belt; we have

(1) $W \times V$ = output of machine in watts.

(2) $\frac{W \times V}{746}$ = E.H.P. (electrical horse-power.

(3) $\frac{\text{Amps.} \times \text{volts}}{V} = \frac{\text{watts}}{V}$ = width of belt required (W).

(4) $\frac{\text{H.P} \times 746}{V} = \frac{\text{watts}}{V}$ = width of belt (W).

(5) $\frac{\text{H.P.} \times 746}{W} = \frac{\text{watts}}{W}$ = velocity of belt (V).

(6) $\frac{\text{H.P.} \times 33{,}000}{W \times V}$ = driving tension per inch width of belt (T).

(7) $W \times T$ = total driving tension.

Example I.—A dynamo runs at 1,000 revolutions per minute with an 8in. diameter driving pulley. The output of the machine being 100 amperes at 50 volts, what width of belt is required to drive it?

Since speed of band = circumferential speed of pulley

$$\therefore \text{speed of band} = \frac{8 \times 3{\cdot}1416 \times 1{,}000}{12} = 2{,}094\text{ft. per minute.}$$

then by (3) width of belt $= \frac{\text{Amperes} \times \text{volts}}{V}$

$$= \frac{100 \times 50}{2{,}094} = 2{\cdot}4\text{in.}$$

So that a belt 2·4in., or, say, 2½in., wide will be required.

Example II.—A 20-h.p. motor has a 14in. diameter pulley running at 850 revolutions per minute; what width of belt will be required for the motor in order to transmit the full output of the machine?

$$\text{Velocity of belt} = \frac{\text{Dia. of pulley} \times \pi \times \text{revs. per min.}}{12}$$

$$= \frac{14 \times 3{\cdot}1416 \times 850}{12} = 3{,}116\text{ft./min.}$$

Then by (4)

$$\frac{\text{H.P.} \times 746}{V} = \text{width of belt} = \frac{20 \times 746}{3{,}116} = 4{\cdot}788\text{in. or say } 4\tfrac{7}{8}\text{in.}$$

Example III.—A steam-engine with a 7ft. diameter driving pulley running at 90 revolutions per minute is capable of developing 30 b.h.p. at the driving pulley; what width of belt will be required, and what will be the difference in tension in pounds pull of the tight over the slack side of the belt?

$$\text{Velocity of belt} = \frac{7 \times 12 \times 3{\cdot}1416 \times 90}{12} = 1{,}979\text{ft./min.}$$

$$\text{Width of belt} = \frac{\text{H.P.} \times 746}{V} = \frac{30 \times 746}{1{,}979}$$

$$= 11{\cdot}31\text{in., or, say, } 11\tfrac{3}{8}\text{in. wide.}$$

Then by (6) $\frac{\text{H P.} \times 33{,}000}{W \times V}$ = driving tension per inch width, and $\frac{\text{H.P.} \times 33{,}000}{W \times V} \times W$ = total driving tension or difference in tension in pounds pull of the tight side over the slack

$$= \frac{30 \times 33{,}000 \times 11{\cdot}31}{11{\cdot}31 \times 1{,}979} = 500\text{lb } \textit{pull.}$$

The simplicity of this rule, and the easy way in which calculations of this kind can be performed, will at once be apparent from the foregoing examples.

Convexity of Pulleys.—All pulleys, as far as possible, should be slightly convex or rounded on the face for the purpose of maintaining the band in the middle of the pulley, but as to what amount or extent they should be rounded is a point which engineers do not generally agree upon. Therefore it is no uncommon thing to see a band running upon two pulleys with a wide difference of convexity or roundness of face. In fact, one can see at times a band running from one pulley (probably the driving pulley) with a very much rounded face to another which has a perfectly flat face, which, to say the least, would not be considered good practice, and would be very injurious to the band, especially where dry resin is freely used. In order to adopt a universal convexity for all pulleys, the writer would suggest that to square the width of the face in inches and add 10in. would give us a radius in inches for striking the arc of convexity, from which sheet steel gauges could be made. For example, take a pulley with a 6in. face, then by the rule $6 \times 6 + 10 = 46$in. radius, an amount which will be found to be thoroughly consistent with good practice, and one that will give very satisfactory results for any reasonable width of face or diameter of pulley. But to speak to an average workman about squaring the width of the face in inches to find a radius for striking the arc of convexity would probably sound like so much Greek; therefore, for the sake of completeness, it may be added that the square of a number is the number multiplied by its own value, which process would be spoken of as raising a number or quantity to its second power, and is usually denoted by placing a small figure 2 over the quantity to be raised.

As 7^2 = 7 squared = the second power of $7 = 7 \times 7 = 49$, or 6^2 = 6 squared = the second power of $6 = 6 \times 6 = 36$, or $10^2 = 10$ squared = the second power of $10 = 10 \times 10 = 100$. This is called the process of involution. Therefore, the square of the face in inches of a pulley with a 10in. face equals 100in., and adding the extra 10in., the sum, 110in., would be the radius in inches for striking the arc of convexity.

Centrifugal Force.—When belts are in motion, they are subjected to a stress arising from the action of centrifugal force, in addition to that due to transmission of power. But this only need be taken into account when belts are running at a very high velocity, such as 4,000ft., 5,000ft., or even 6,000ft. per minute. At the ordinary speeds which are usually adopted for long lengths of line shafting, and, in fact, general machine driving, the effect of centrifugal force does not materially affect our calculated results. Therefore, this force need not be considered in any case when the belt velocity is below 3,000ft. per minute. But in anything

Digitized by Google

above 3,000ft. per minute the effect of centrifugal force tends to impair the general efficiency. It is often remarked that a good long belt drive is far more efficient than any short one, and also that all belts run to the highest point of the pulley. Both of these statements are apt to be somewhat misleading, and should therefore never be accepted as a general rule, because there may exist certain conditions which would render a long drive less efficient than a reasonably short one. It can be shown that in the case where both driving and driven pulleys are of the same diameter there is no particular advantage in having a good long drive (whatever that means), for precisely the same results can be obtained with a reasonably short (say 8ft.) drive as with an 80ft. one without any extra tension on the short band or machinery, both bands being the same width and thickness. But if we take a case where the diameters of the two pulleys differ, say, with a ratio of 4 or 5 to 1, then it is an advantage to have a fairly long drive of belt. But here, again, it can be shown that it is utterly impossible to get the lengths of the two band arcs or band grips in the same ratio as the two diameters of the pulleys, however long that belt drive may be.

SOME ACTUAL RESULTS OBTAINED DURING THE USE OF VARIOUS ELECTRIC WIRING SYSTEMS.

BY A. H. M.

Amongst the large amount of information which has lately been forthcoming in the Press with regard to the above problem, there appears to be a singular lack of report as to *actual experience* resulting from an extended use of the various systems. Electric wiring is far from being in its infancy, and a sufficiency of time has certainly elapsed to enable the seeker after definite information to find some sure ground to walk upon. The writer has been conversant with the principal forms of wiring in use for the past 15 years, and ventures to think that the merits and demerits of each are not difficult to define in the light of actual results obtained in practice.

Undoubtedly the basis of all decisions as to which type to adopt must be a careful consideration of the conditions under which they are expected to give satisfaction. It is scarcely possible to lay too much stress upon the above point, seeing that one system will give excellent results when used in surroundings where another would prove a lamentable failure. The writer was recently asked by a friend, who is an architect and surveyor by profession, what class of protection he recommended for electric light wiring, as he (the architect) had just had a lot of trouble with an installation in which the wires were run in metal tubes. As anticipated, the tubes proved to be of the cheap close-joint variety, and after a short length of time so much moisture had collected in the system that the insulation had completely broken down and rendered re-wiring necessary.

There is ample confirmation on every hand that the above class of tubing is quite unsuitable unless the position is an extremely dry one, and certainly should never be buried in plaster. Careful inspection of a breakdown such as mentioned above, constantly reveals the fact that both the surface of the insulating covering on the wire and the interior surface of the tube are covered by beads and films of moisture, partly caused by condensation and partly by water entering the crevice of the tube by capillary attraction. The actual wire carrying the current is therefore only separated from the earthed metallic tubing by the thickness of the insulating covering, and this soon becomes saturated by the moisture, causing such a strain upon the insulation that breakdown is inevitable.

Now let us suppose that in the place of the ordinary close-joint tubing a type had been used provided with an insulating and *non-absorbent* lining. By the adoption of this class of tube we obtain the advantages of a large decrease in the amount of moisture forming by condensation, and a complete absence of water introducing itself through the longitudinal joints. There is also an immense increase in the insulation resistance between the conductor and the earthed tubing. As the result of actual experience the writer has no hesitation in saying that a light form of close joint tube, provided with an insulating and non-absorbent lining, will give excellent results wherever great mechanical strength is not required.

Where great mechanical strength is necessary a solid drawn or brazed tube must be employed, but this must also be fitted with an insulating and non-absorbent lining, or trouble is certain to ensue. An ideal form of lined tubing would consist of a tube of whitewood, thoroughly saturated with paraffin wax and protected by an outer tube of thin enamelled steel. The above should not be expensive to manufacture, and would give excellent results in all respects, and would have the great advantage that the wiring could be easily and safely drawn in.

The question of satisfactorily earthing a system of metal tubing when the joints are not screwed has recently received considerable attention. A very satisfactory plan is as follows: The interior of the socket and the entering end of the tube must be roughly cleaned by passing a rasp over them, and when in position a thin strip of hard copper is driven in between the tube and socket. The copper strips should be about 1in. long and ½in. wide, and cut from different gauges of sheet metal in order to meet all cases.

So far no mention has been made of our old friend wood casing, but the writer nevertheless holds it in the highest esteem. Where it affords a sufficient mechanical protection, and is not objected to on account of appearance, it should be used, and will prolong the life of the cables to a greater extent than any metallic tubing in existence. The writer recently saw some wiring removed from wood casing, where it had lain for 17 years, and the condition was excellent. This has been proved by practice countless times, and there cannot be the slightest doubt that wood casing is a most excellent and satisfactory device, and may be used with absolute confidence where not subject to rough usage.

NEW X-RAY TUBE.

In a communication to the *Electrical Review* of New York, Dr. J. Mount Bleyer, of that city, claims that he has discovered a new composition of glass which admits of the combined generation and transmission of X-rays and bi-ultra-violet rays of the highest quality and quantity in one tube. Dr. Bleyer states that he is not yet prepared to give the exact chemical formula of this glass, because the analysis is not yet ripe for publication. The tube is constructed upon the same principles as any ordinary X-ray tube, except that the main bulb is made entirely of this new glass, and the ends which hold the metallic anode and cathode are made of flint glass and sealed into the main bulb. Experiments are stated to have shown that this type of tube, placed in circuit, gives X-rays and bi-ultra-violet rays a perfectly free passage through its walls in a combined state. The exposure of platino-cyanide or willimite to these rays caused them to exhibit a vivid fluorescence at short or long range, and the application of the electric test to the bi-ultra-violet rays showed their presence in great quantity, Dr. Bleyer remarking that they were the most powerful he had ever witnessed. The colour of both rays viewed in the new tube partakes of a bluish opalescent hue instead of the greenish hue perceived in the ordinary type of tubes. The flint glass which is blown into this new glass tube can be seen, when the tube is generating the rays, to give off the green colour which is the fluorescent property of the flint glass. Dr. Bleyer opines that the new tube will prove a great acquisition to therapeutics. In a footnote he credits Mr. G. J. Monahan, of New York, with the construction of the first tube. The issue of the *Electrical World* of New York dated the 2nd inst, just to hand, contains a letter from the latter stating that it was he who made the discovery some three months ago, and that he exhibited it to Dr. Bleyer. He adds that the tube has no special features, except that it fluoresces blue, and does not absorb or cut off so much of the rays as flint glass is likely to do.

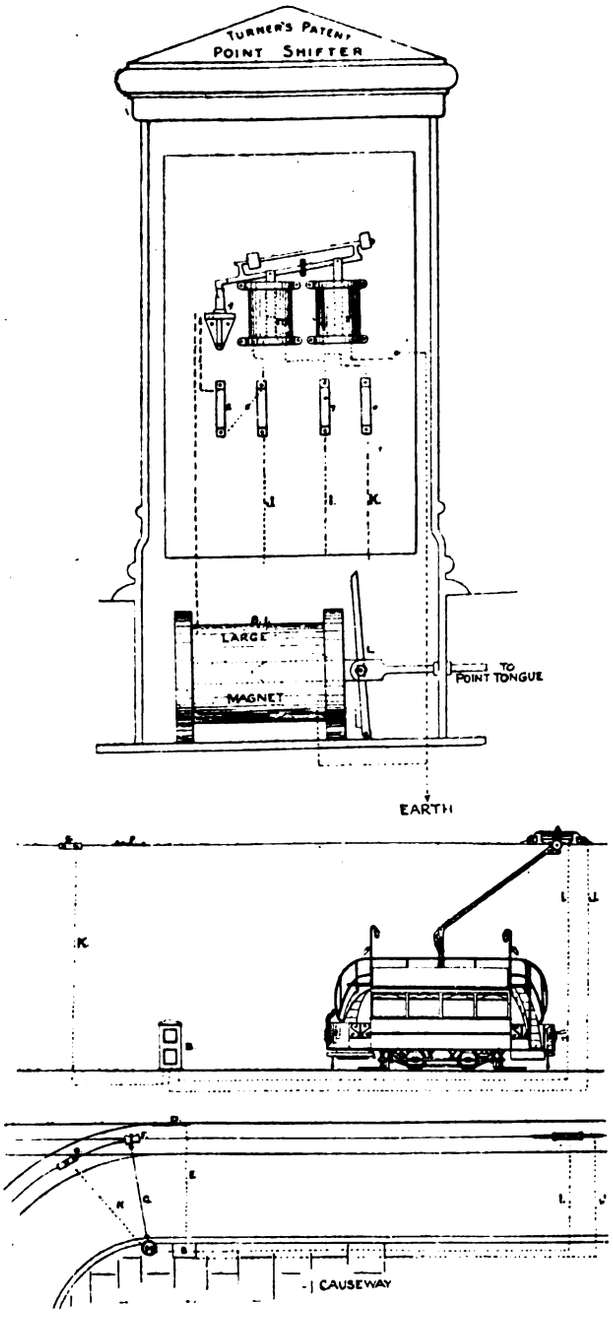
TRADE NOTICES AND NOVELTIES.

Electric Tramway Supplies.

Messrs. S. Dixon and Son, Limited, Swinegate, Leeds, have recently published a well-printed catalogue of their various specialities in the way of electric tramway supplies. An apparatus for automatically controlling the overhead and rail points of electric tramways is illustrated and described as follows: The cast-iron box, B, contains a powerful electro-magnet or solenoid, B 1, wound to suit the line voltage, having a core of suitable size and stroke to pull over both the rail points and that of the overhead wire. The core, B 2, is connected to rail point tongue, D, by rod, E, and also to a lever projecting upwards, L, so that when desirable the points



may be actuated by hand. A flexible steel cable, G, connected to this lever, L, is carried to the overhead point, F, and adjusted so that the necessary movement is obtained at each when the lever is thrown over either by hand or by the electromagnet, B 1. The working of this magnet is controlled by an electrically-operated switch, mounted in the same street box. This switch consists of two electromagnets, M and N, mounted, as shown, side by side, the cores of each being connected to a pivoted lever forming the moving portion of the switch, at one end of which are the switch contacts, which are, however, well insulated from the lever, while at the other end is fixed an adjustable balance weight, so that when the core is attracted into the magnet M the switch is closed, and when attracted into magnet N, opened. The closing of this switch completes the circuit thus: from the overhead trolley wire, by means of cable, J, main fuse, 1, connecting wire, 2, fuse, 3, to switch, 4, to magnet, B 1, to earth or rails, thus causing the core of magnet, B 1, to be attracted and the points pulled over. On the switch being opened the core is released, and the points resume their original position by the tension of a powerful spring. The necessary current for working the magnets, M and N, is derived from the line as follows: At a position some convenient distance short of the rail point a section insulator, A, is fixed on the overhead cable. This insulator is of the pattern known as the "Air-Gap." An insulated cable, J, is connected through the main switch and fuse, 1, to magnet M, from there to the return fuse, 7, back through wire 1 to insulated piece of section insulator, A. A cable, K, is also run from hanging switch, C, to box, B, and on to the switch and fuse and connected to magnet N, and then to the rails. The motorman on nearing a junction, and not wishing to turn on to a branch route, will, on nearing the insulator, A, switch his motor controller off, and coast through the insulator, thereby not interfering with the points in any way. Should he, however, wish to turn on to the branch line, he would, on approaching the section insulator, A, keep his controller on. Current would then flow from the line by means of wire 2 to switch and fuse 1 through magnet M, through return fuse, 7, wire 1, to insulated piece, A, down the trolley to the motor, S, and thence to rails. The large magnet would then become energised by means of the switch, 4, being closed and pull over the points. The car, having passed the points, now comes to the hanging switch, C, and the trolley head, making contact, sends the current through wire, K, to switch and fuse 6 through magnet N, and thence to rails, thus opening switch, 4, and releasing core of magnet B 1, thereby allowing the points to resume their original positions. We understand that the Leeds, Bradford, and Sheffield Corporations have adopted this automatic point shifter after 12 months' trial.

"Stellite" S.D. Telephones.

The Electric and Ordnance Accessories Company, Limited, Stellite Works, Birmingham, are issuing a new catalogue, containing 32 pages, dealing with "Stellite" S.D. telephones, which are claimed to be especially suitable for use with existing electric bells and general short-distance or domestic work. The S.D. telephone in its simplest form consists of a hand set with receiver and transmitter, and fitted with a special speaking key. This key is a very important item, as it obviates the danger of conversations being overheard through the telephone being inadvertently left off the hook. With the Stellite instrument, no matter in what position it is left, it is impossible for any conversation to be transmitted unless the speaking key is depressed. A further advantage is that immediately the hand is removed from the hand set the key automatically breaks the battery circuit, thus preventing the cells unnecessarily running down or wasting. Very concise directions are given for fitting this telephone to any existing bell circuit. The instrument for the kitchen end is similar to that just described, but without the speaking key. It is supplied with a switch hook on wall rosette and a length of flexible twin bell wire for convenient attachment to the bell. The pair of telephones retails at 15s., and should find a ready market. The list shows numerous other patterns, including portable telephones which may be carried from room to room and used wherever a special bell push has previously been fitted, portable table sets, special sets for ringing in either direction, isolation sets, etc. The last-named would appear to be exceedingly useful in any case of emergency where it is desired to establish immediate communication between two rooms, a very likely contingency in the case of contagious disease. Several pages are given up to describing a special intercommunication telephone. The same hand set is used as already described. After a conversation the hand set is hung on the hook, causing the selector to return to its normal position, and the instrument is then ready for a further call. In the table set the bell is fitted at the back of the circular base, and the whole is mounted on a metal pedestal. After a dozen or so diagram connections, several pages are devoted to views of large public buildings recently fitted throughout with the Stellite long-distance telephones, mention being also made of the electrophone transmitter which was used to transmit many of Mr. J. Chamberlain's fiscal reform speeches direct to London.

THE SUPPLY OF ELECTRICITY BILL.

Lord Wolverton's Select Committee of the House of Lords on the 7th inst. resumed consideration of the Supply of Electricity Bill.

Mr. Coward, K.C., on behalf of the London County Council, expressed agreement with most recommendations, but objected to the proposed exemption of the "bulk companies" from the purchase terms of the Electric Lighting Acts. He thought that the fact of these electrical undertakings having been to some extent altered in their character should not be used to the advantage of the companies and to the disadvantage of the local authorities, and in that way upset the statutory bargain which Parliament established in 1882 and 1888. In these Acts of 1882 and 1888 both the date and the terms on which the companies should be purchasable had been clearly enunciated, and the

Digitized by Google

companies would have no ground for complaint if at the time specified in the Acts of Parliament they received the amount which it was ordained they should receive, and it did not seem to the Council that it mattered whether that amount was given piecemeal by this or that authority provided they received the amount specified at the time Parliament specified—namely, 1931. Of course, they admitted that it would be impossible in many parts of London for them to purchase electrical energy undertakings self-contained, but, at any rate, they asked that they should not be put in any worse position than they now were in to purchase.

Mr. Pelham, on behalf of the Board of Trade, pointed out that the Bill did not propose to exempt from purchase any company which was now purchasable.

Mr. Coward said his remarks applied to bulk companies supplying in different areas from that in which their generating station was established, and he submitted that, while it was clearly the intention of Parliament that such companies should be purchasable, at present there was no body that could buy them, because they ran into different areas. He hoped the Board of Trade would amend the Bill, so as to remedy what was obviously a defect in it.

Mr. Balfour Browne, K.C., who appeared for 18 electric light companies in favour of the Bill, said Clause 2 enabled the Board of Trade by provisional order to empower the breaking up of any road, tramway, or railway for the purpose of enabling electricity to be brought into an area of supply from a generating station situated outside that area. He thought the veto by local authorities, which had stood in the way of the development both of electric lighting and tramways, ought never to have been given, but at the same time it was most important that everybody interested should be heard by the Board of Trade, as was provided by Clause 6. As to the question of purchase, as applied principally to bulk companies, he contended that the Act of 1888 did not apply. The local authorities wanted to supply power even outside their own districts and become traders in electricity. That was going further than the Acts of 1882 and 1888 contemplated.

Mr. Baggallay, K.C., for the gas companies, objected to the grant of compulsory powers to the electrical companies to purchase land by provisional order, as it would put those companies in a preferential position compared with gas companies.

Lord Robert Cecil, K.C., for the borough councils, objected to the removal of the veto, and urged that the proposal to increase the facilities of competition with the metropolitan boroughs in regard to the supply of electrical power was not justified by any facts which had come to light since the Act of 1888.

The **Chairman** announced that the committee had agreed to pass the preamble of the Bill subject to modifications of the clauses.

The committee subsequently discussed the amendments which have been submitted by the Department itself and by the London County Council, the County Councils' Association, the Association of Municipal Corporations, and other bodies.

On July 11 Clause 3 ("Supply in Bulk") was dealt with.

Mr. Fitzgerald, K.C., moved an amendment, the object of which was to secure that, in regard to the supply of electricity in bulk, a local authority should be in the same position as a company.

Lord H. Cecil, K.C., also had a similar amendment.

Mr. Morse (in the absence of Mr. Balfour Browne, K.C.) opposed the amendment on behalf of the electric lighting companies.

Mr. Hutchinson, on behalf of the Gas Companies' Protection Association, associated himself with the arguments of Mr. Morse.

Mr. Rostron also opposed the amendment for the metropolitan gas companies.

Mr. Pelham, assistant secretary to the Board of Trade, informed the committee that the proposal brought forward by Mr. Fitzgerald was not recommended by the Joint Committee, on whose report this Bill was largely based. In reply to Lord Stanley of Alderley, who asked why it was more dangerous for a local authority to give a supply to a company than to another local authority, he said it would raise difficult issues for a department to decide. It would put upon the Board of Trade the decision of what is and what is not municipal trading, and he preferred to leave that decision to Parliament.

Finally, the **Chairman** said that the committee were of opinion, by four to one, that the amendment must be struck out.

FORTHCOMING EVENTS.

MONDAY, JULY 18.

York Corporation.—At 4 p.m., opening of the extensions of the electricity works.

WEDNESDAY, JULY 20.

Industrial Freedom League.—At 4 p.m., Westminster Palace Hotel. Address by Lord Brassey.

THURSDAY, JULY 21.

Heating and Ventilating Engineers.—(July 21-22). Meeting at Liverpool.

Institution of Mechanical Engineers.—Conversazione.

FRIDAY, JULY 22.

Junior Institution of Engineers.—At 3.15 p.m., visit to Messrs. Bryant and May's factory, Fairfield Works, Bow.

Institution of Mechanical Engineers.—At 11 a.m., general meeting. "Design and Test of a Modern Steam Power Plant," by Mr. E. G. Hillier.

The Institution's Visit to America.—The complete programme has been received from the American Institute, and copies may be had on application to Mr. Lloyd. Particulars will appear in our next issue.

British Association.—At Cambridge, week commencing Aug. 17.

LEGAL INTELLIGENCE.

TRAMCAR OBSTRUCTION.

An appeal from the decision of the Leigh (Lancs.) magistrates came before the Lord Chief Justice, Mr. Justice Kennedy, and Mr. Justice Phillimore last week.

The driver of a cart had, it was alleged, wilfully obstructed a tramcar. The Leigh magistrates refused to convict, and the appeal was from their decision. The cart-driver had insisted on keeping on the left side of the road. At one part of this Leigh line the distance between the tramway and the kerb was insufficient to admit of a vehicle passing between the tramcar and the kerb. The cart-driver might have passed by going to the other side of the road, but instead of doing that he insisted in going on his right side of the road, with the result that both vehicles stood facing each other for about 50 minutes, neither of them giving way. At the end of that period, however, the tramcar backed to the loop.

Counsel contended that the magistrates ought to have convicted under the circumstances.

Counsel on the other side argued that the magistrates could not have found the respondent guilty of wilful obstruction unless the law required that all vehicles should get out of the way of the tramcars in every case, but he submitted that the law did not say so.

Their Lordships were of opinion that the case ought to go back to the magistrates, with the direction that there was no absolute right on the part of the driver of any vehicle to put a tramcar to any amount of inconvenience. But there was a duty on a driver to act reasonably towards the tramcar. On the other hand, the tramcar driver had no right to say he would go on and make the cart cross the road, if by acting reasonably he could avoid putting the driver of the vehicle to this inconvenience.

AN ELECTRIC SHOCK.

At Dudley County Court last week **Mrs. Rose Annie Law** brought an action against the British Electric Traction Company to recover £50 damages for injuries sustained.

Plaintiff stated that on May 16 she travelled from Brierley Hill on an electric car, and when near her home she asked a young man, who was descending from the top deck, to stop the car. For the purpose of assisting her to step off the car she laid hold with her right hand, from which she had removed her glove, of the brass rod in the middle of the step, placed there to assist passengers in boarding and alighting. She immediately experienced an electric shock which rendered her semi-conscious, with the result that on stepping into the road she fell, tearing her costume, which had cost five guineas and was quite new. In consequence of the shock and injuries sustained by the fall she had to keep her bed for over a week, during which she was under medical treatment. She was still suffering from the shock.

It was stated for the defence that directly after the accident the car was examined by a policeman, the motorman, and conductor, but neither could detect that any part of it was "alive" with electricity, and no other passengers complained of having felt any shock. The car was subsequently subjected to several tests, and was found to be perfectly satisfactory. It had been used on many occasions since, but no complaint as to an electric shock had been made by any passenger. It was contended that it was impossible for plaintiff to have experienced a shock in the manner described.

The jury gave a verdict for the plaintiff, awarding her £10.

ELECTRIC TRAMWAYS CONSTRUCTION COMPANY.

The petition of Mr. A. J. Pain for winding up the Electric Tramways Construction and Maintenance Company, Limited, came before Mr. Justice Buckley. The petition had been directed to stand over by Mr. Justice Byrne in March, for 14 days, pending an action by the company being decided for rectification of the register by striking out the petitioning shareholder's name. There had been repeated postponements of the trial of the latter, which was finally set down for trial before Mr. Justice Kekewich on Monday next.

Mr. Wilkinson said that when the case was last mentioned to Mr. Justice Kekewich, Mr. Martelli applied for an adjournment till certain other proceedings, which involved the whole question, had been concluded. It was impossible to complete the evidence, by reason of certain papers being in the custody of the Solicitor to the Treasury for the purpose of the criminal proceedings. On Monday when he (Mr. Wilkinson) brought his motion before Mr. Justice Kekewich, the learned judge intimated that he did not think it would be right to go into the civil proceedings, having regard to the fact that the criminal proceedings were still pending.

After hearing Mr. Martelli and Mr. Ware, all parties assented to the petition standing over till the second petition day next sittings, and in view of the uncertainty of the termination of the criminal prosecution

THE AUTOMATIC TELEPHONE COMPANY (1903).

A summary of accounts and some observations on the affairs of this company, which is in liquidation, have been issued by Mr. G. S. Barnes, senior official receiver and liquidator. A total deficiency of £10,051. 10s. 4d. is disclosed as regards the contributories, after payment of the creditors in full. The assets mainly consist of shares in patents, as to the value of which the official receiver has not at present any definite information. The statement of affairs has been filed by Mr. Max Margowski, the late managing director. Dr. H. G. Sworn, the other director, and Lieutenant E. G. Festing, R.N., the late secretary, have declined to concur in the statement, on the ground that they are not in possession of sufficient information to enable them to express an opinion as to the accuracy of the figures. The official

Digitized by Google

receiver adds that certain effects have been sold by auction under an order of Court, but the proceeds, about £500, will not be dealt with until a decision has been given on the validity of a claim made by Mrs. Margowski as mortgagee.

COMPANIES' MEETINGS AND REPORTS

BRITISH ELECTRIC TRACTION.

The eighth ordinary general meeting of the British Electric Traction Company, Limited, was held on Monday at Winchester House, Sir Charles Rivers Wilson, G.C.M.G., C.B. (chairman of the Company), presiding.

The **Chairman**, in moving the adoption of the report (which was published in our issue of the 1st inst.), said that the net profit for the past year, before paying interest on the debenture stock, was £249,517, as against £232,836 for the preceding 12 months. The increase in the profits was entirely represented by the increased productiveness of their investments in the associated companies; in fact, this source of their profit was increasing while the other sources of profit were, in the aggregate, diminishing. This was a satisfactory feature, for it was mainly in this direction that they would have to look for their future profits. After paying the interest on debenture stock, the preference dividends, and the interim dividends on the ordinary shares, they had available for further distribution a sum of £78,138. They proposed a further dividend of 6 per cent., making 6 per cent. for the year, and to carry forward the balance of £38,148, which was £13,236 more than last year. The dividend on the ordinary shares was 2 per cent. less than last year, and the reason why the smaller dividend was recommended was that there was a large proportion of capital which had not had time to become revenue earning. It was important to recognise, however, that very decided progress had been made by the Company. They were operating nearly 400 miles of tramway, light railway, and omnibus routes, as against 200 miles five years ago, and were carrying about 220,000,000 passengers per annum, as against 55,000,000 in 1899, and the total traffic receipts were £1,162,000, as against £315,000 in 1899. These figures, although large, did not show the real progress made. The best figure for comparison was to take the number of passengers carried and the receipts per route mile, and this showed how substantial the progress had been. In 1899 they carried per route mile 250,000 passengers, and the receipts were £1,455 per mile. For the past year the passengers numbered 554,000 per route mile, and the receipts were close on £3,000 per route mile. The improvement was largely the result of the adoption of electric traction. In 1899 the majority of the lines were worked by steam and horses, but in 1903 the majority were worked by electricity. The conversion of the lines had involved a large increase in the capital accounts of the associated companies, but the original idea was not only to enormously increase the receipts, but also to reduce the cost of working, and this had been done. The chairman alluded to the important work which had been done during the year in consolidating the Company's various interests in the Birmingham and Midland district. They had now secured an Act of Parliament enabling them to convert the Brighton and Shoreham tramways to electric traction, and to extend them to Worthing, and had obtained a prolonged tenure for 42 years, with a favourable purchase clause. They had also obtained Acts of Parliament enabling them to complete the important network of tramways and light railways in the vicinity of Croydon. They hoped soon to make a commencement with the work of construction. In the case of the Hove and Worthing tramways, they had till 1908 to complete them, and in the case of the Croydon district tramways the period allowed for construction was close upon them in regard to some of the lines, but extended to 1907 in regard to others. The present policy of the directors was to limit, as far as possible, further capital commitments. They were not promoting or entering upon new schemes, but desired to complete what they had undertaken, and he was glad to inform the shareholders that they had made financial arrangements which would enable them to proceed with what they had in hand, so that it would be unnecessary to make any public issue for some time to come.

Mr. Emile Garcke, M.I.E.E., seconded the motion.

The report was unanimously adopted.

On the motion of the **Chairman**, seconded by **Mr C. Shirreff B. Hilton**, the retiring director (Sir Charles W. Freemantle, K.C.B.) was re-elected.

The proceedings terminated with a vote of thanks to the chairman and directors.

TELEGRAPH CONSTRUCTION AND MAINTENANCE.

The half-yearly meeting was held at the Company's offices, Sir R. G. W. Herbert presiding.

The **Chairman** remarked that the accounts were made up to the end of last year, and there would be no advantage in entering on the consideration of the intermediate position of the Company's accounts at this period. During the half-year they had not been able to announce any important development in their works; they had not made any considerable contracts for the construction or laying of cables, but they had taken advantage of the opportunity afforded by the comparative cessation of work to continue the renovation and readaptation of their factories, and getting everything into very good condition. The whole of the ships of their fleet were in excellent condition, and they were ready for any work that might present itself at very short notice. Having alluded to the progress being made in the pension fund, to which he was glad to say no application had been received as yet, the chairman concluded by moving that a dividend of 5 per cent. for the half-year, making 10 per cent. for the year, be approved of.

This was seconded and carried unanimously.

NEW GENERAL TRACTION.

The general meeting of this Company was held on the 6th inst., Baron d'Erlanger presiding. Particulars of the report were given in last week's issue.

In moving the adoption of the report, the **Chairman** pointed out that the directors were doing everything in their power to reduce expenditure. The total saving to be effected from June this year would amount to over £800 in management charges. While the directors could in certain limited measure reduce expenditure, they were powerless to accelerate the Company's source of revenue, which was dependent upon the receipts and dividends paid by the companies in which their capital was invested. There was a slight increase in the dividends received for 1903 compared with those for 1902, and, judging by the gross receipts to date of the Coventry, the Philadelphia, and the Norwich tramways, they were led to believe that a further slight improvement would be shown for the year 1904. It was only, however, in a couple of years' time that they would be able to draw accurate conclusions of the earning capacity of the Philadelphia line and of the altered tramway system of Coventry. For some time they could not expect the revenues of the Traction Company to cover the latter's full fixed charges. Recent cables from Philadelphia advised them that at last the entire system had been connected up, and that the cars were to be running over it this week. They had spent £3,000 upon the system since the date of the balance-sheet, and they would have to spend another £4 000 on street paving and various items. Additional cars would have to be provided, and if the traffic at all responded to their hopes, the power station would require further extension. Underground lines were now in construction, which, when complete, would give a certain strategical importance to the line. The £60,000 subscribed on the prior lien bonds had been taken entirely by the directors and their friends, and the Board would probably invite tenders from the shareholders for the remaining prior lien bonds.

The motion was carried.

ELECTRIC AND GENERAL INVESTMENT.

The ordinary general meeting was held on the 6th inst. at Winchester House.

Mr. G. Herring presided, and, in moving the adoption of the report and accounts (particulars of which appeared in our issue of the 24th ult.), stated that the net profit for the year amounted to £15,804, and out of this the directors recommended a further dividend of 1s. per share, making, with the interim dividend already paid, a total of 10 per cent. for the year. This would absorb £1,000, and, in view of the market depreciation of the investments held by the Company, they had decided to place £5,813 to the reserve fund. Although the dividend of 10 per cent. was smaller than that paid in previous years, he reminded the shareholders that for every £1 share held by them they had received in dividends the sum of £3. 18s. 1d.

The motion was carried unanimously.

METROPOLITAN ELECTRIC SUPPLY.

An extraordinary general meeting of this Company is called for Tuesday next, when the distribution of the purchase money received from the Borough Council of St. Marylebone is to be considered. A bonus at the rate of £6 per £10 share is to be proposed, and also an honorarium to the directors. At the same time the chairman will explain the views of the Board as to the best method of dealing with the balance of the purchase money.

CHILI TELEPHONE.

The report states that the aggregate number of subscribers at all centres at the end of the year was 5,814, as compared with 5,371 at the beginning, or a gain of 443 for the year. The gross revenue in Chili from all sources was 916,542dol., against 841,193dol. in 1902-1903, and the expenditure in Chili was 422,409dol., against 401,519dol., leaving the net income from all sources of 494,133dol., against 439,674dol. The average rate of exchange for the year was 16·36d., as compared with 15·68d. in the previous year. The balance to the credit of the revenue account, including £2,637 brought from the previous year, is £31,207, of which £14,010 has been carried to reserve for renewal of plant, etc. An interim dividend of 3s. per share, less income tax, was paid on Jan. 14 last, and the directors now recommend a final dividend of 4s. per share, less income tax, making 7 per cent. for the year, and leaving a balance of £2,502 to be carried forward. Of the debentures which matured on March 31 this year, £21,000 has been paid off, and arrangements have been made to extend the remainder, amounting to £35,000, until such time as the finances of the Company will permit of their being also paid off.

EDMUNDSON'S ELECTRICITY.

The report for the year ended March 31 last, to be presented at the meeting on the 21st inst., states that, including £11,734 brought forward from last year, the net profit, after payment of debenture and other interest, amounts to £64,406. After deducting dividends on preference shares paid and accrued, and an interim dividend at the rate of 5 per cent. per annum on the ordinary shares, there remains a balance of £40,111. The directors recommend a final dividend on the ordinary shares at the rate of 9 per cent. per annum, making 7 per cent. for the year; to be written off goodwill account £5,000, added to reserve fund £5,437, and carried forward £13,923. During the year 20,000 preference shares, 20,000 ordinary shares, and £92,196 debenture stock have been issued. The premiums received in respect

Digitized by Google

of these issues, less expenses, amount to £24,562, and have been added to the reserve fund, which, with the contribution proposed to be made from revenue account, will be thereby increased to £70,000. The large increase in the capital has been necessary for the completion of central stations in new towns and large extensions to many of the older works, and will bear fruit in due course in the form of increased revenue.

NATIONAL TELEPHONE.

The report for the half-year ended June 30 last, to be presented at the meeting on 22nd inst., states that the income accrued in respect of the business of the half-year amounts to £984,600, an increase of £90,017. Working expenses for the half-year amounted to £567,072, an increase of £57,658. The net result for the half-year (after deducting the Post Office royalties, amounting to £90,703) is a profit balance of £326,825, an increase of £23,668. The rentals carried forward for unexpired terms of running contracts amount to £937,297, an increase of £62,913. Out of an available balance of £258,286 the directors recommend a dividend at the rate of 6 per cent. per annum on the preferred stock and 5 per cent. per annum on the deferred stock, transferring £100,000 to reserve fund and carrying forward £9,370. The sum of £394,654 has been expended on capital account during the half-year in the erection of 19,615 additional exchange and private stations and in the construction of underground works.

ELECTRICAL POWER STORAGE.

The profit for the year to May 31 last, including the balance of £594 brought forward, is £10,360. Out of this sum the directors have carried £3,500 to the reserve fund and £1,000 to the contingent fund. They recommend again the payment of a dividend of 6 per cent. on the ordinary share capital, which will absorb a further £5,389, and leave £470 to be carried forward. The buildings, plant, tools, etc., have been maintained in thorough repair and condition at a cost of £4,297, which sum has been provided out of revenue. The Company's products continue to give satisfaction to its customers, the volume of orders increasing steadily year by year.

NEW COMPANIES REGISTERED.

R. H. Longbotham and Co., Limited.—Capital, £10,000. Objects: to acquire and carry on the business of R. H. Longbotham at Ings Foundry, Wakefield, and at Newcastle-on-Tyne, as R. H. Longbotham and Co.; to manufacture and deal in machinery, implements, rolling-stock, instruments, tools, apparatus, and hardware of all kinds; and to carry on the business of electrical and mechanical engineers, etc. Registered office: Ings Foundry, Ings-road, Wakefield.

Hunter Electric Candle Lamp Company.—Capital, £800. Objects: to acquire certain inventions relating to electric incandescent lamps and fittings, and letters patent and benefit of application relating thereto; to adopt agreements with N. Burt and Co. and C. C. Regnart; and to carry on the business of manufacturers of and dealers in electric candle lamps and fittings, etc. Registered office: 17, Newman-street, Oxford-street, W.

Kingsbridge and South Devon Electric Lighting and Traction Company, Limited.—Capital, £2,000. Objects: to carry on at Kingsbridge, Salcombe, and elsewhere in Devonshire, the business of an electric lighting and power company in all its branches, and to construct, fix, and maintain any necessary generating stations, cables, wires, lines, accumulators, lamps, works, and conveniences, etc. Registered office: 25, Victoria-street, S.W.

Dean and Burden Bros., Limited.—Capital, £3,800. Object: to acquire the business of motor manufacturers and engineers carried on at Friary-lane, Salisbury, as Burden Bros., and to carry on the business of engineers, manufacturers of motors of all kinds, etc. Registered office: Friary-lane, St. Aun-street, Salisbury.

APPOINTMENTS VACANT.

Rolling-Stock Superintendent, London County Council Tramways Department. Salary, £400 per annum. Applications by 10 a.m. on July 16.

Resident Engineer, Mains Superintendent, and an Installation Inspector, a Meter Superintendent, and an Accountant, St. Marylebone Electricity Department. Applications by 3 p.m. on July 20. See advertisement in last issue.

Clerk of Works, Handsworth, Birmingham, during the erection of the electric supply station. Salary will be 3½ guineas per week. Applications to the Clerk by noon on July 19.

Electrical Engineer, as test-room assistant in large Midland factory. Apply, Box No. W 9, *Electrical Engineer* Office. See advertisement.

Storekeeper, Carliale Electricity Works. Wages, 25s. per week. Applications by July 25.

Mains Assistant, West Ham Electricity Works. Salary, £2. 5s. per week.

New Issue.—The list of subscriptions for the issue of 46,600 ordinary shares of £5 each at par by the Electric Supply Corporation, Limited, will close to-day.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Worksop.—Tenders are to be obtained for cables, etc., for mains, and additional feeder, estimated at £1,000.

Rhyl.—The Urban District Council invite tenders for 1,400 yards of ·2 concentric feeder cable. Tenders by 18th inst.

Murcia.—The Post and Telegraph Department, Madrid, require tenders for an urban telephone system at El Dano del Beal. Tenders by 27th inst.

Belmez (Spain).—The Municipality require tenders for electric lighting by 20th inst. Particulars from Secretary to the Ayuntamiento, Belmez (Cordoba), Spain.

Batley.—The Corporation invite tenders for one 350-kw. steam dynamo and switchboard extension for same. Specifications, etc., may be obtained from the Borough Electrical Engineer. Tenders by July 16.

Keighley.—The Corporation invite tenders for machine tools for the workshop at the car depôt in South-street. Particulars may be obtained from Mr. J. M. Smyth, Electricity Works, Keighley. Tenders by July 18.

Plymouth.—The Education Authority invite tenders for electric light installation at the Municipal Technical School. Specifications, etc., can be seen at 11, The Crescent, Plymouth. Tenders by 12 noon on 21st inst.

Bromley.—The Council invite tenders for the provision of a 15-kw. electric light installation at the refuse destructor works. Specifications, etc., may be obtained at the office of the Borough Engineer. Tenders by 3 p.m. on July 26.

Stockport.—The Gas and Electricity Committee invite tenders for supply of 3in. and 4in. cast-iron mains and for irregulars from 3in. to 4in. Specifications, etc., can be obtained from the engineer, Mr. S. Meunier. Tenders by July 20.

Devonport (Tasmania).—The Town Board invite tenders for the supply and delivery of alternatively 50 or 100 smallest-size meters to read direct in B.O.T. units on 220-volt direct-current circuits. See advertisement in former issue.

Glasgow.—The Trustees of the Clyde Navigation invite tenders for two electric 32-ton coaling hoists for Clydebank Dock. Specification, etc., may be obtained from Mr. Geo. H. Baxter, 16, Robertson-street, Glasgow. Tenders by noon on July 25.

Whitby.—The Urban District Council invite tenders for (a) distributor and street-lighting cables; (b) network and service-boxes. Specifications, etc., may be obtained from Mr. H. S. King, electrical engineer. Tenders by 10 a.m. on July 18.

Walthamstow.—The Urban District Council invite tenders for supply, delivery, and laying cables, troughing boxes, etc. Specifications, etc., may be obtained from Mr. J. Enright, 68, Lincoln's-inn-fields, W.C. Tenders by 5 p.m. on July 22.

Rochdale.—The Electricity Committee invite tenders for erection of the buildings in connection with the extension of the engine-room. Particulars may be obtained from Mr. C. C. Atchison, Electricity Works, Rochdale. Tenders by noon on July 18.

Preston (Lancs.).—The Corporation invite tenders for supply and delivery at their power station of machine tools. Specifications, etc., may be obtained from Mr. Walter H. Tittensor, Tramway Power Station, Holmrook-road, Preston. Tenders by July 18.

Suakim.—The Public Works Department require tenders for 220 miles of galvanised wire, 1,100 yards ditto, 1,500 screws and bolts, 6,000 insulators, 1,500 creosoted fir telegraph poles, and 3,000 oak poles, to be delivered at Suakim between Oct. 1 and Dec. 1.

Dartford (Kent).—The Metropolitan Asylums Board invite tenders for installation of fire-alarms at Darenth Asylum, Dartford. Specifications, etc., may be obtained at the office of the Board, Embankment, E.C., on and after 9th inst. Tenders by 10 a.m. on 20th inst.

Hackney.—The Guardians invite tenders for fitting up a system of electric fire-alarm bells at their Homerton establishments. Specification, etc., can be obtained from Mr. Frank R. Coles, Clerk's Offices, Sidney-road, Homerton, N.E. Tenders by 2 p.m. on July 27.

Wimbledon.—The Urban District Council invite tenders for extensions to the present refuse destructors at their electricity works. Particulars may be obtained from the Engineer and Surveyor to the Council, Council Offices, Wimbledon. Tenders by 10 a.m. on 25th inst.

Ashton-under-Lyne.—The Guardians invite tenders for the supply and fixing of telephones at new hospitals and nurses' home at the union. Specifications, etc., may be obtained at the office of Messrs. J. Eaton and Son, Stamford-street, Ashton-under-Lyne. Tenders by July 20.

Plymouth.—The Corporation invite tenders for (25) steam alternator, etc.; (26) Lancashire boilers, with mechanical stokers; steam, exhaust, and other piping; ejector, condenser, valves, etc. Specifications, etc., may be obtained from the Borough Electrical Engineer. Tenders by Aug. 15.

Aston Manor.—The Corporation invite tenders for the supply, delivery, and erection complete of pipework, etc. Specifications, etc., may be obtained from Mr. T. J. Ballard, Electricity Works, Chester-street, Aston Manor. Tenders before 12 noon on July 28. See advertisement in former issue.

Homerton.—The Metropolitan Asylums Board invite tenders for installation of telephones at the Eastern Hospital, Homerton, N.E., and Western Hospital, Fulham, S.W. Specifications, etc., may be obtained at the office of the Board, Embankment, E.C., on and after 9th inst. Tenders by 10 a.m. on 20th inst.

Radcliffe.—The Urban District Council invite tenders for the construction of permanent-way, including copper bonding, of about 5 miles

Digitized by Google

1 furlong of route length line, being 6½ miles single line with passing places. Specifications, etc., may be obtained from Mr. W. L. Rothwell, engineer to the Council. Tenders by 16th inst.

Wigan.—The Corporation invite tenders for (1) hand reversible three-wire battery, booster, and switchboard; (2) compound-wound double-field balancer; (3) cables. Specifications, etc., may be obtained from Mr. J. Slevin, borough electrical and tramway engineer, Bradford-place, Wigan. Tenders by 12 noon on July 19.

St. Pancras.—The Borough Council invite tenders for the supply and erection of main switchboard at the King's-road power-house, Camden Town, N.W. Specifications, etc., may be obtained at the offices of the Electricity Department, 57, Pratt-street, N.W. Tenders by 12 noon on July 19. See advertisement in former issue.

Manchester.—The Tramways Committee invite tenders for the supply of the following: (a) 350 steel tramway poles; (b) 20 miles of hard-drawn copper trolley wire; (c) 6,000 yards of 2in. steam tube, together with the necessary fittings. Specifications, etc., may be obtained on application to Mr. J. M. M'Elroy, Tramways Department, 55, Piccadilly, Manchester. Tenders by 5 p.m. on July 18.

Dartford.—The Urban District Council invite tenders for carrying out an extension of underground and pilot cables drawn into existing spareways, and for the laying of private and public lighting cables, together with all necessary roadwork, junction boxes, etc. Specifications, etc., may be obtained from Mr. W. Kay, clerk to the Council. Tenders by 12 noon on the 19th inst. See advertisement in former issue.

Greenwich.—The London County Council invite tenders for the manufacture, delivery, and erection at the tramways electricity generating station at Greenwich of the following plant: two 24in. centrifugal pumps and motors, one 3in. centrifugal pump and motor, two 8in. by 8in. three-throw air-pumps and motors, one 3in. artesian well pump, fixed and rotary strainers, etc. Specifications, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 4.

Rochdale.—The Corporation invite tenders for the supply, delivery, and erection at the Electricity Works, Rochdale, Lancashire, of two steam turbines direct connected to two 3-phase alternators, or alternatively for alternators connected to high-speed triple-expansion engines (Contract No. 7); and also for one motor-driven 3-phase alternator (Contract No. 8). Specifications, etc., may be obtained at the offices of Messrs. Lacey, Siller, and Leigh, 2, Queen Anne's-gate, Westminster. Tenders by July 18. See advertisement in former issue.

Lerida, etc. (Spain).—The *Gaceta de Madrid* of June 22 contains notices calling for tenders for the construction and working of telephone systems in Lérida and in El Llano del Beal, in the province of Murcia. In each case tenders are to be presented either to the Dirección-General of Telegraphs, 10, Calle de Carretas, Madrid, or at certain local offices within 30 days of publication of the notice in the *Gaceta*. In each case the concessionaire will have to pay to the State 10 per cent. of all receipts; the maximum period of the concession will be for 20 years, and the adjudication will turn on the reduction of this period. A provisional deposit of 2,000 pesetas (or about £57) is required in the case of the Lérida telephone service, and of 500 pesetas (or about £15) in the case of the El Llano del Beal telephone service.

Berga, etc. (Spain).—The *Gaceta de Madrid* for June 26 publishes a Royal decree calling for tenders for the installation and working of a telephone system and central stations at Berga and sub-stations at Gironalla, Puigreig, Balsareny, Sallent, Castelladral y Cardona. Tenders will be received within 30 days' date of publication at the office of the Dirección-General of Posts and Telegraphs, 10, Calle de Carretas, and at the office of the Civil Governor, Barcelona, a provisional deposit of 2,000 pesetas (or about £57) being required from persons tendering. The maximum period for the concession is for 20 years, and the adjudication of tenders will turn on the reduction of this period. The *Gacetas* may be seen on application at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, E.C., any day between 10 a.m. and 5 p.m. (Saturdays 10 a.m. to 1 p.m).

Reichenberg (Austria-Hungary).—The project for the establishment of a central distributing electric power and light plant in the Reichenberg land district has taken definite form. The territory included is about 10 miles square, and 24 towns and villages have joined in the movement and subscribed to the capital stock. Some 10 more are expected to join. The population of the district, exclusive of Reichenberg, is about 60,000. Stock is subscribed at present to the amount of £40,000, and this it is proposed to increase to £80,000. The principal purpose of the corporation will be the distribution of electric light and power, with the possibility of installing and working a system of suburban electric tramways. Tramway and light franchises for the city of Reichenberg are at present owned by private corporations, and at their expiration it has been generally supposed that the city would take over and conduct the enterprises. Negotiations are pending, however, which may change the situation in this respect. Communications regarding equipment, etc., may be addressed to directors Alfred Ginskey, Maffersdorf, and Dr. Richard Pirkl, Reichenberg.

RESULTS OF TENDERS.

Batley.—The contract for steam-piping and superheater for the electric lighting station has been let to J. Spencer, Limited, Wednesbury.

Dover.—The Corporation have accepted the tender of G. Lewis and Sons, Dover, at £1,222. 10s., for additions to Corporation electricity works.

Radcliffe (Lancs.).—The Urban District Council have accepted the tender of Ferranti Limited, Hollinwood, Manchester, for the supply of direct-current electricity meters.

Southport.—The following tenders have been accepted: Procter and Co., stoker, £73; Dick, Kerr, and Co., 200-kw. alternator, £608. 10s.; Bellias-Morcom, alternators, £41. 9s..

Stepney.—The Borough Council have accepted the tender of the Electric Motor Supply Company, Nottingham, at £237. 8s., for wiring and fitting the Whitechapel public baths for the electric light.

Croydon.—The Electricity Committee recommend for acceptance the tender of Babcock and Wilcox, at £997, for supply of materials and erection of steam-pipe in connection with extensions at the electricity station.

Colchester.—The Council have accepted the tender of Davey, Paxman, and Co. to supply one Peache 550-h.p. engine for £1,320; and Henley's Telegraph Works Company for cables for main extensions at £1,360. 10s.

Exeter.—The Electric Lighting Committee have recommended the acceptance of the tender of the British Westinghouse Company to erect a reciprocating engine for generating the tramway supply for £2,260, which is the lowest in its class.

Exeter.—The Corporation have accepted the tender of the British Westinghouse Electric Company, London and Manchester, at £2,260, for one 200-kw. triple-expansion engine and traction generator, with condenser steam, exhaust, circulating water pipes, etc., or, alternatively, one 200-kw. steam turbo-generator, with condenser, pipes, etc.

Warrington.—The Town Council have accepted the following tenders: J. A. Ewart, at £2,935. 15s. 8d., for the construction of the permanent way of light railway No. 1 from Stafford-road to Victoria-square, Stockton Heath; Babcock and Wilcox, at £957, for the supply of four mechanical stokers; and that of Bell Bros., at £450, for the supply of water-softening plant.

Derby.—The following tenders have been accepted: Rawlinson and Sons, at £19. 15s., for the supply of a telescopic trimming ladder; C. Potter, at £12. 10s., for painting the engine-room at the electric lighting station; E. Buxton, at 5s. per post, for painting the street electric light lamp-posts; Radford and Greaves, at £30. 10s., for the construction of an underground transformer chamber; Derby Coal Company, T. and G. Walker, and G. L. White for coal.

London.—The London County Council Education Committee have received the following tenders for installation of electric light, etc., at the Poplar Technical Institute:

Alliance Electrical Company, 137, Regent-street, W.*	£666
Electrical and General Engineering Company, 17, Gracechurch-street, E.C.	718
Wenham and Waters	770
Drake and Gorham, 66, Victoria-street, S.W.	787
J. H. Holmes and Co., 17, Soho-square, W.C.	790
Mossop and Co., 52, Queen Victoria-street, E.C.	940
Peacock and Jessop, 329, Goldhawk-road, W.	950

* Recommended for acceptance.

Loughborough.—The Town Council have received the following tenders for the five steel roof principals required for the boiler-house at the electricity station:

W. Hayward and Sons, Wolverhampton	£184	0	0
A. Faulks, Loughborough	171	0	0
Drew-Beer and Co., Westminster *	138	15	0

* Accepted, plus £25 on agreement to complete work in five weeks.

Swindon.—The following tenders have been recommended for acceptance: Frisby and Stubbs, Liverpool, for advertising on the tramcars for a period of three years, at £30 per car per annum, and on the tramway time-tables for a period of three years, at £6 per annum; A. E. Bromley, London, for advertising on the tramway tickets for a period of three years, at £7. 10s. per half million tickets; Glasgow Numerical Printing Company, Glasgow, for the supply of the tramway tickets for a period of three years, at 3½d. per 1,000 tickets; Ticket Register and Punch Company, for letting on hire the ticket punches at 15s. each, with the option of purchasing the same at the end of 12 months at £4 each. The tender of Dick, Kerr, and Co.'s motors for the tramcars has been accepted subject to a three years' guarantee being given, instead of a one year's guarantee as provided in the specification.

BUSINESS NOTES.

TRACTION.

Paisley.—The company's line from Paisley Cross to Johnstone has been opened.

Leicester.—The Narborough-road, Hinckley-road, and Fosse routes have been opened.

Tarperley.—A meeting of the inhabitants have pledged themselves to support the light railway scheme.

Southend.—The Board of Trade have confirmed the Southend-on-Sea and District Light Railways (Extensions) Order, 1904.

Light Railways Act.—The Light Railways Bill, introduced by Lord Wolverton, was last Friday read a third time in the House of Lords and passed.

Halifax.—The Town Council have instructed the borough engineer to commence the construction of the line from Brighouse to Bailiffe Bridge at an estimated cost of £12,746.

Tientsin.—It is stated that the Compagnie Internationale de l'Orient has obtained a concession from the Chinese Government permitting it to instal electric street car lines and electric lighting.

Batley.—The Corporation have decided to communicate with the British Electric Traction Company with a view to ascertaining what the company are doing in reference to the Bradford-road tramways.

Tyneside Tramways Co.—The company's traffic returns for the week ending July 6 were £381. 3s. 8d., this amount showing an increase compared with the corresponding period of last year of £67. 1s. 4d.

Lancaster.—The receipts for the past year up to March last amounted to £4 184, the total revenue being £4,687. The working expenditure totalled £4.653, and the interest and debt redemption charge £2,867, making £7,520. This leaves a deficit of £2,833.

Darlington.—The report of the Electric Lighting and Tramways Committee, remarking upon the fairly favourable results of the tramway working, the system having been gradually brought into operation during the past month, was adopted at the last meeting of the Town Council.

Parliamentary Bills.—In the House of Lords on Wednesday the Charing Cross, Euston, and Hampstead Railway Bill was read a third time. In the Commons the Bristol Tramways (Extensions) Bill and the Manchester Corporation Tramways Bill were read a second time.

Croydon.—At the last meeting of the Corporation the Tramways Committee presented a report recommending that several additional extensions be provided for in the Bill about to be promoted by the Corporation. Ultimately it was decided only to include a route along Grange-road.

Swindon.—A 200-kw. set for the new tramways has been installed, and is ready for supplying current for working the service. This set will be capable of supplying current not only for the seven cars now about to be delivered, but will be sufficient to supply current for 12 or 13 cars if required.

Warrington.—At a meeting of the Town Council, a discussion arose as to the mechanical stokers ordered by the Tramways Committee, on the recommendation of the engineer, certain members criticising a statement that the mechanical stokers were economical. Ultimately the action of the committee was confirmed.

Workington.—The Town Council have decided to ask the Whitehaven Town Council and the Maryport and Cleator Moor Urban Councils to discuss the question of forming a joint committee to consider the advisability of jointly taking over the parliamentary powers of the West Cumberland Tramways Company.

Ayr.—An enquiry under the Private Legislation Procedure (Scotland) Act into the Ayr Corporation tramways draft provisional order, was held at Glasgow on Saturday. The Commissioners found the preamble proved on condition that work A be confined to a loop line. They refused the powers asked under Section 23 to run omnibuses.

Derby.—A trial trip was made on Monday on the Osmaston-road section. The result is reported to have been fairly satisfactory. It is stated that another effort is being made to float the Derby and Ashbourne light railway scheme, the powers for which will expire under the Board of Trade license if they are not utilised within the next few months.

Lincoln.—At a meeting of the City Council, it was stated that the Electricity Works Committee had taken over the undertaking of the Lincoln Tramways Company. After full consideration of the matter, the committee had decided that it would be too expensive to make temporary arrangements for carrying on the traffic while the tramways were being converted.

Airdrie.—The Town Council have arranged with the Airdrie and Coatbridge Tramway Company for lowering certain footpaths to harmonise with the previous lowering of the road, in accordance with arrangements with the company, to enable the latter to carry out the suggestions of the Board of Trade, and to run double-decked cars, the expense of the lowering to be borne by the company.

Bradford.—At Tuesday's meeting of the Corporation a resolution was submitted that application be made to the Board of Trade for sanction to borrow the amount required for the construction by the Corporation of the Baildon section of the Mid-Yorkshire tramways. The cars last week beat their record for Saturday and weekly receipts. On Saturday £1,280 was taken, and the week's receipts totalled £4,965.

Stockport.—The Hazel Grove Urban District Council have approved heads of an agreement with the Corporation, leasing the tramways to the latter in the event of their purchasing the company's undertaking. It is reported that the company have decided to run a service of motor 'buses to Hazel Grove, the negotiations with the Corporation having, apparently, been abortive. It is also stated that a rival company is to be formed for the same purpose.

Bootle.—At a meeting of the Highways Committee a letter was read from the town clerk of Liverpool, requesting the construction of tramways in Breeze-hill and Merton-road to connect with Stanley-road and Strand-road lines to the north docks; or, alternatively, the construction of lines in Breeze-hill and Balliol-road to Regent-road, and offering to construct and maintain the portion of Balliol-road over the old quarry. The town clerk was instructed to reply that the proposals could not be accepted.

Tees-side.—The Stockton Town Council have accepted the offer of the Imperial Tramways Company to pay the Council £200 per annum for 25 years in respect of every route mile of tramway owned or worked by the company within the borough, the Council to withdraw the petition against the company's Bill. At a meeting of the Middlesbrough Town Council it was resolved to reject the agreement submitted by the company. The Bill will therefore be opposed in the House of Lords by the Middlesbrough Corporation.

Electric Traction Co.—The dissolution is announced of this company, the syndicate which promoted the Central London Railway. The holders of the ordinary £10 shares obtain under the winding-up an allotment of Central London debenture stock equivalent to £17. 5s. for every £10 share held in the syndicate. The holders of the £1 deferred shares get £43 per share. It is understood that there will be a further distribution of £1 on the ordinary shares and £7 on the deferred. There are 29,880 ordinary shares and 1,200 deferred.

West Riding Tramways Bill.—This Bill came before Mr. J. W. Lowther, chairman of committees, in the House of Commons last week as an unopposed measure. It has already passed the House of Lords. Its object is to authorise the Wakefield and District Light Railway Company to construct a tramroad and other works in the West Riding. The Bill authorises the company to raise an additional £165,000, and empowers them to borrow £55,000 of this sum. Formal proofs were given, and the Bill was ordered to be reported for third reading.

Dukinfield.—At the last meeting of the Town Council, it was stated, in reply to several questions, that the current for all the cars running between Stalybridge and Hyde and Dukinfield to Throstle Bank was obtained through the Dukinfield sub-station. The sub-station was really doing more work then it should do. The Joint Board desired that the motormen should gain more experience in the command of the cars before they put them upon Crescent-road. It was expected that cars would be run to Mossley and Millbrook in about a fortnight.

Birmingham.—At last week's meeting of the Corporation the scheme for extending the tramway system, of which we recently gave particulars, was adopted practically in the form prepared by the Tramways Committee, who were instructed to draft an empowering Bill. A suggestion was made that a line should be constructed from Bristol-road to Mosely-road, and the chairman of the committee promised that the matter should have consideration, but added that he scarcely regarded the proposal seriously, as it would entail the widening of the railway bridge at Camp Hill.

Yarmouth.—The following recommendation of the Tramways Committee was adopted at Tuesday's meeting of the Town Council: "That on receipt of the Royal assent to the Corporation Bill now before Parliament, the Council instruct the borough surveyor to at once submit the necessary plans to the Board of Trade for their assent, and that immediately on their approval the work of constructing the tramway in Blackfriars-road from St. Peter's-road to Queen's-road be proceeded with, so as to ensure the completion of that section of the tramway before the commencement of the fishing season, at a cost of £2,200, in addition to the rails already in stock."

Wigan.—The minutes of the Tramway Committee, confirmed at the last meeting of the Town Council, stated that the Pemberton and Platt Bridge routes would be in use again in a few days, and that

Digitized by Google

they would be ready to run on the Pemberton section as soon as the Pemberton Council had finished their work. They had been constantly in negotiation with the Hindley District Council for running powers in regard to the short length in their district—namely, from Amberswood Common—but their demands were such that the committee could not agree to them, as they were absolutely unreasonable, and the committee had decided to run the cars in that district as far as the boundary of Ince, which would be Amberswood Hotel.

North Wales Electric Power and Traction Co.—The 10,000-h.p. hydraulic station is now well under way, and 18 miles of new railway line are in course of construction. The pipe line and dam works are in full swing, and it is expected that current will be ready by the end of the year. A considerable portion of the 10,000 h.p. to form the first installation has been already booked. The whole contract, including the supply of six 1,000-kw., 10,000-volt turbo-alternators, 10 250-h.p. locomotives, the whole of the rolling-stock for the new line, the complete erection of the hydraulic works, transformer stations, and over 100 miles of high-tension transmission lines, is being proceeded with by the sole contractors, Messrs. Bruce Peebles and Co., Limited.

Rhondda.—At the meeting of the District Council the Legal and Parliamentary Committee reported the completion of the purchase of that portion of the Pontypridd and Rhondda tramways situated within the district of the Council, and that a letter from Mr. G. E. Morewood, 23, Leadenhall-street, London, had been considered respecting the leasing of the tramways. The committee had replied that the Council would be prepared to receive offers for the grant of a lease of the Council's rights on the basis of a term of 42 years, the lease to contain a proviso that in the event of the Council repurchasing the system it should be treated as a going concern, and asking Mr. Morewood to submit alternative terms for the grant of a lease for a similar period, leaving the Council's statutory rights of purchase unaffected.

Ashton and Stalybridge Tramway Deadlock.—There are indications of a settlement of the deadlock in the through running of the Ashton and Stalybridge electric cars. At a meeting of the Stalybridge Joint Electricity Board last week it was resolved that the sub-committee meet the Ashton Tramway Sub-Committee to discuss the situation, but that they be not empowered to finally settle matters. They are to report to the Joint Board, which will give its final decision. The chairman of the Ashton Tramway Committee expressed himself as highly gratified at the turn of events. He was extremely desirous of bringing about a settlement, and should do all he could towards that end. One ticket only would be required for each through passenger, the destination being indicated by punching. Through tickets could, of course, be apportioned, each authority having equal length of track.

Bury.—At a special meeting of the Tramways Committee the town clerk read a letter from the town clerk of Salford submitting proposals for the granting to Salford of running powers on portions of the Bury and Radcliffe tramways, and various other suggestions, as the result of interviews which the chairman, the manager, and himself had had with the chairman of the Salford Tramways Committee, their town clerk, and manager, and it was resolved that the consideration of the matter be deferred. The system adopted by this committee on April 29 last in connection with the reduced fares for workpeople—whereby any passenger desiring to travel at such rates was required to fill up an application form stating place and nature of employment—has been discontinued. A suggestion that ½d. fares should be adopted was rejected, it being considered that it would be premature to introduce such an arrangement. It is expected that the Manchester-road section will be finished within two or three days.

Huddersfield.—The extension of the Longwood section was opened last week. Huddersfield, the pioneer of tramway municipalisation, is also first in the field amongst the municipalities of the country in the matter of supplying motor power for the haulage of coal. Some time ago the Tramways Committee were approached by a company at Lindley with the object of securing a light railway service to carry coal from the Hillhouse railway siding to the works of the company at Lindley, a distance of some three miles. A seven years' agreement for the Corporation to carry all the company's coal was entered into, and the work of constructing the necessary permanent way to connect the two points was commenced. That in the company's mill yard has been finished, and it is expected that the whole of the work will be completed in a few weeks. The Tramways Committee will restrict the hours of haulage to slack hours in the morning passenger traffic, and none will be carried in the afternoon. It is considered probable that other large consumers of coal will enter into arrangements with the Corporation for a similar service.

Leeds.—The Committee of the House of Commons, Mr. Heywood Johnstone presiding, gave their decision on the clauses of the Corporation's Bill relating to tramways on Tuesday. The committee gave the Corporation power to carry animals, goods, and other things on the existing tramways of the Corporation. Regarding Clause 102, which proposed that the Corporation should be in a position to make agreements with adjoining authorities to work tramways, the clause was granted to the extent of giving the Corporation power to enter into such agreements, but without purporting to give that power to other persons, companies, or local authorities. This decision, however, would not affect the Horsforth case. The York-road extension has been opened. It is hoped to have the extension along Belle Vue-road and Moorland-road to Hyde Park ready by the 25th inst. Proposals are on foot for the running of lines through Bramley to Rodley, and to the boundary on Whitehall-road, thus placing Drighlington in touch with the city. Arrangements are being made for the adoption of a system of high-tension transmission.

Wolverhampton.—The report for the year ending March 31 shows that the section operated by horse traction resulted in a loss, after allowing for interest, sinking fund, and depreciation, of £1,275. The electric traction account shows that the income in excess of working expenses amounted to £8,611. 15s. 8d. Repayment of loans, interest, and sinking fund came to £6,488. 3s., leaving a balance of £2,123. 12s. 8d. The contributions to the renewals fund for the past year, based on figures supplied by the electrical engineer and borough surveyor, amounted to £3,213. 13s. 6d., so that, after setting aside this amount, the loss on the year's account appears as £1,090. 0s. 10d. The committee anticipate that now the additional routes on the Willenhall-road and the Wednesfield-road are in operation, and the Waterloo-road and Stafford-road line approaching completion, the undertaking offers every prospect of proving a financial success. The following particulars refer to the year's working of the electrical section: miles of single track at March 31, 1904, 13·4; number of miles run, 507,527; number of passengers carried, 4,555,435; traffic receipts from passengers, £23,204. 12s. 2d.; traffic receipts from parcels, £47. 4s. 3d.; total traffic receipts per mile run, 10·9953d.; working expenses (exclusive of renewals), £14,910. 17s. 7d.; working expenses per mile run, 7·051d.; renewals, £3,213. 13s. 8d.; average number of cars running daily, 15.

New Lifeguard.—A new tramway car lifeguard was tried last week on the Oldham, Ashton, and Hyde tramways. A dummy, resembling a human being, was laid across the track, and a heavy double-decked car fitted with the Nuttall and Pearson contrivance was set running at full speed towards it. The car met the obstacle, the cradle descended, swept it up, and stopped the car without the least apparent injury, and without the driver touching a single lever. Four trials were made, each of them giving very satisfactory results. In the last trial the driver was presumed to have seen the obstacle, and by the action of one foot on a small lever the car was pulled up in a minimum of time. The patentees of the contrivance claim that it accomplishes three distinct objects with one mechanism—viz., the moment the obstacle touches the gate in front of the car, the cradle falls, at the same time applying the brakes to the wheels, and cutting off the current from the motors, bringing the car to a standstill. Moreover, if the driver sees the obstacle a short distance ahead, he can stop the car as described above, bringing all three actions into play instantly. In addition, the patentees claim that the cradle cannot ride the obstacle. The reason is that the cradle is usually placed at an angle of at least 45deg. before it loosens itself, but in the present one it flies loose instantly. The driver can also apply his ordinary brakes distinct from the lifeguard.

Newcastle.—It was decided that a meeting of the Parliamentary and By-laws and Tramways Committees be held as soon as possible to consider the proceedings on the Tyneside Tramways Bill. A sub-committee was appointed for the purpose of considering the actual expenditure on the tramways, and also with a view, if possible, of reducing the expenditure on revenue account. At a meeting of the Finance Committee the city treasurer presented a report upon the question of depreciation of the tramways. It was resolved that the report, together with the tramway estimates, be sent out to each member of the committee for consideration at next meeting. The past 13 weeks have yielded £48,915. 13s. 7½d., as against £43,126. 15s. 11½d. in the same period of last year, an increase of £5,788. 17s. 8d. It appears that a meeting between the Tramways Committee and the company has been arranged, and was fixed to take place yesterday. The Corporation, it is stated, are now desirous of coming to an amicable arrangement. Proposals have been forwarded to the company, the effect of which is that there shall be an interchange of traffic between the centre of the city and Wallsend, on similar terms to those prevailing in Liverpool. It is proposed that a number of the Tyneside Company's cars should be allowed to run to the centre of the city, and that the Corporation pay so much for the use of each car which will be under their control. In turn there is a proposition that the Corporation should be allowed to run a certain number of their cars to Wallsend.

Glasgow.—The following are particulars of the year's working o the Corporation tramways: The revenue amounted to £724,851. 5s. 8d., and the working expenses, including depreciation, to £496,266. 14s. 11d., thus leaving a gross balance of £228,584. 10s. 9d. The revenue of the previous year was £656,572. 7s. 11d., and the working expenses, including depreciation, £431,870. 2s. 11d., leaving a gross balance of £224,702. 5s. This year's gross balance thus shows an increase of £3,882. 5s. 9d. The gross balance of £228,584. 10s. 9d. has been applied in meeting interest and sinking funds, etc., on cost of Govan and Ibrox tramways, interest on capital, sinking fund, parliamentary expenses, and "annual payment to the common good," these payments amounting in all to £147,794. 0s. 6d. The net balance remaining amounts to £80,790. 10s. 3d., of which £62,000 has been applied in writing down the cost of buildings, ducts, cables, overhead equipment, and power station plant, the balance of £18,790. 10s. 3d. being added to the general reserve fund. Although the gross revenue for the past year shows an increase of £63,278. 17s. 9d. over that of the previous year, the average traffic revenue per car mile has decreased from 11·19d. to 10·58d. This decrease is chiefly due to the augmented service of cars which is now given on all routes. The average working expenditure per car mile shows a slight increase from 5·21d. to 5·26d. The total number of electric cars in stock is 682, and the Corporation have decided to build another 100.

Wednesbury, etc., Tramways.—A conference took place last week at the offices of the British Electric Traction Company, Birmingham, at which several officials of the company were present, including Mr. Emile Garcke (chairman) and Mr. J. A. Lycett, and representatives of the municipal authorities of Dudley, Tipton, Coseley, Wednesbury, etc. The interview took place at the invitation of the company, and the chief subject of discussion was the question of the reconstruction of the lines for the purpose of electric traction. On behalf of the local authorities it was pointed out that the action of the company in ceasing to run the old steam trams had caused serious inconvenience to the travelling public; that until some satisfactory arrangement had been made as to the reconstruction of the lines the company should allow the steam cars to continue running; that the company had undertaken

Digitized by Google

by an agreement with the Tipton District Council to electrify the line in that parish by the end of April last; and that, pending the removal of all the difficulties in connection with the reconstruction of the whole of the two routes, the company should at least electrify the line from Dudley to Princes End—a 2d. stage. In regard to the stoppage of the tramway between Dudley and Wednesbury, it was explained on behalf of the company that the service had been unprofitable, and had been carried on solely for the convenience of the travelling public, and, further, that they could not incur additional loss by a continuance of steam traction. Reference was then made to the report of the company's engineer, stating that subsidences had occurred. A continuance of such subsidences would cause a deflection of the joints of the rails, with a consequent leakage of electrical current, and damage to overhead poles might also result, involving danger to the public. Quite apart, however, from the probability of further subsidences, the position of the company, as explained by their officials, was that it is quite impracticable, because of the serious loss of power, to electrify the line in sections, and that the principal obstacle was the present inability of the company to come to a satisfactory settlement with the Corporations of Wednesbury and Dudley in reference to their powers of purchase. In addition there were difficult complications in regard to the original shareholders of the South Staffordshire Tramway Company, from whom the British Electric Company leased the lines. It was intimated that the terms upon which the company had invited the Dudley and Wednesbury authorities to exercise their powers of purchase, but which were not disclosed, had not been accepted, and that, as matters now stood, there was a probability of the whole question having to be submitted to arbitration. Mr. Garcke stated that the company were anxious to electrify the line from Dudley to Wednesbury, and from Wednesbury to Darlaston, but nothing could possibly be done in this direction until a settlement had been arrived at between the company and the Corporations of Dudley and Wednesbury in regard to the purchase by those authorities of the sections of the lines within their areas, and new leases of them secured by the company. In regard to Wednesbury, he had formulated a scheme which he hoped might meet the difficulty so far as that authority was concerned.

London County Council.—An important scheme for the relief of London's congested traffic was foreshadowed at Tuesday's meeting of the London County Council, the nature of which is indicated by the two following clauses in a resolution which was carried unanimously: "That, having regard to the necessity for providing additional traffic facilities in London, and to the importance of linking up the Council's northern and southern tramway systems, it be referred to the Improvements Committee to consult the Highways and Bridges Committees, and to report at an early date: (1) whether the South-Eastern and Chatham and Dover Railway Company are contemplating the rebuilding of Charing Cross Station and the widening of Hungerford Bridge; (2) whether the Council can be advised to take the opportunity of submitting to Parliament a scheme for the acquisition by the Council of Charing Cross Station and Hungerford Bridge, providing the railway company with a site for a new terminus station on the Waterloo side of the river in place of the present terminus at Charing Cross, and erecting for general traffic a new road bridge of sufficient width and capacity to take a double line of tramway in the centre of the roadway, so that the Council's northern and southern tramways from Aldwych to Waterloo could be linked together." The transfer of the London, Deptford, and Greenwich tramways has been completed, and the lines are now being worked by the Council. The Woolwich Borough Council have decided to call the attention of the County Council to the great delay which is taking place with regard to the Well Hall tramway and to the importance of proceeding with the work of laying the tramway track during the widening of the roadway, otherwise this work, which is now in hand, must be postponed, or a large sum will be wasted through breaking up the carriageway for the purpose of laying the tramway; also to ask for a reply as to whether they are prepared to allow the Borough Council to carry out the work; and also to ask the County Council to state definitely whether they are prepared to accept the quotation of the Borough Council for the supply of electricity, as the lighting of a large portion of the borough is being held over pending such reply. The Council's receipts from tramways for the week ending the 2nd inst. amounted to £13,329, against £11,495 for the corresponding week last year; and for the period April 1 to that date to £156,931, against £130,780. The County Council have informed the Wandsworth Borough Council that they do not propose to submit the Clapham Common to East-hill and Streatham to the county boundary tramway schemes to Parliament in the 1905 session, but that they would be considered in connection with any schemes which might be placed before the County Council for the 1906 session. The Finsbury Borough Council have resolved to urge upon the County Council the need for accelerating the arrangements for reconstructing Goswell-road for electric traction, so that certain paving work decided upon by the Borough Council may not be delayed. The County Council Tramways and Improvements Bill was again before a Select Committee of the House of Lords on Monday. Further evidence was called in respect of three new lines which the London County Council propose to construct in the south-eastern district. The first line will run from the Horniman Museum to the Lewisham High-road, the second will couple up Lewisham and New Cross, and the third will run from Lewisham to Eltham-road. It was also proposed, in connection with these lines, to reconstruct the existing tramway in Rushey-green and High-street, Lewisham, for electrical purposes. The committee sanctioned the construction of these lines, and the consideration of other parts of the Bill was adjourned. The tramways will be on the conduit system, and the average cost per mile will be about £40,000. At Wednesday's meeting of the House of Lords Committee evidence was given in respect of tramway No. 4, a double line from Grove-vale along East Dulwich-road to the eastern corner of Peckham Rye Common. Short lines would connect with the systems of tramways and give access to the termini at Waterloo, Westminster, and Blackfriars Bridges. Mr. M. Fitzmaurice, C.M.G., engineer to the Council, gave particulars of the line, the estimated cost of which was £42,050; in addition street improvements would cost £1,500. Evidence was also given on behalf of the County Council in support of line No. 10, a double line 1¼ miles in length from Lordship-lane, Camberwell, to London-road, Lewisham. The cost was estimated at £51,000, and street improvements would be necessary at a cost of £21,500. A petition against this line was presented by the London, Camberwell, and Dulwich Tramways Company. The Camberwell Borough Council strongly supported both routes. As the result of a conference, the County Council had undertaken to purchase the whole undertaking of the London, Camberwell, and Dulwich Company for £6,500. The committee decided to pass tramways Nos. 4 and 10.

Leith.—The first instance of an appeal from the decision of the local Commissioners under the Private Legislation Procedure (Scotland) Act to a Joint Committee of both Houses of Parliament occurred last week in the case of the Leith Corporation Tramways Order (Confirmation) Bill. The two Houses decided to remit the Bill to a joint committee chiefly on the question whether the Edinburgh District Tramways Company should be given a *locus standi*. The Earl of Camperdown was elected chairman of the committee. Mr. Hutchinson appeared for the promoters of the Bill, who are the Leith Corporation, and Mr. Balfour Browne, K.C., and Mr. Forbes Lankester represented the Edinburgh District Tramways Company. Mr. Hutchinson explained that in 1871 the Edinburgh Street Tramways Company was incorporated and authorised to construct certain tramways in Edinburgh and Leith. Among the tramways was one communicating between Golden Acre and the Newhaven district of Leith. In 1874 this was abandoned under an Act of Parliament, and an omnibus service was required to be set up in lieu of the tramways which had been abandoned. That was the price the company had to pay for the abandonment of the tramways. In 1884 the Edinburgh Northern Tramways Company was incorporated, and it was authorised to construct a line from Princes-street to Golden Acre, but the company was required, as the price of the powers Parliament had given it, to continue the 'bus service into Leith from Golden Acre. The 'bus service became part and parcel of the tramway undertaking of the Northern Company, and existed now. In 1893, under the Tramways Act, the Edinburgh Corporation purchased the whole of the lines in Edinburgh, with the exception of the Northern route, and so stepped into the shoes of the Edinburgh Street Tramways Company. The lines in Leith still remained the property of the Street Tramways Company, and these lines the provisional order empowered the Leith Corporation to purchase. In 1897 the Corporation of Edinburgh purchased the Northern system, and so took upon themselves the obligation to work the whole of the undertaking, including the omnibuses. A proviso to that effect was inserted in the Act of 1897. The petitioners, the District Tramways Company, came on the scene, and leased from the Corporation of Edinburgh the whole of the Edinburgh tramways, including the omnibus service. The relation between the petitioners and the Edinburgh Corporation with respect to this tramway undertaking was that the petitioners were to work the whole. The question arose whether the petitioners appeared before the committee as lessees. Section 19 of the Tramways Act was incorporated in the 1897 Act. It gave authority to a local authority to lease tramways of which they might be possessed, but subject to the condition that the lease was to be approved by the Board of Trade. His contention was that unless the lease was approved by the Board of Trade it was not a lease which complied with the provisions of the Tramways Act. His second point was that, granted the District Tramways Company might establish that they had a lease, the approval of which by the Board of Trade was not necessary in order to make it valid, then the company were coming as the lessee of the Edinburgh Corporation, who were not there complaining. The District Company were seeking to extinguish that part of the undertaking of their lessors which under the lease it was under an obligation to work—namely, the omnibus section. Mr. Balfour Browne, K.C., said that if tramways had been made to Trinity instead of an omnibus service, there would have been no question that the Leith Corporation would have been bound to buy the whole of the tramways in its district. The omnibuses were only a poor substitute for tramways. As they were connected with the Edinburgh tramway system at Golden Acre, the obligation had been put upon his company to work them, although they ran in the burgh of Leith. That was an onerous obligation, as the omnibuses were run at a loss. The Corporation of Leith was going to compete with the District Company, as they proposed a new tramway along Pilrig, which would compete with the line from Trinity and Golden Acre to Princes-street. The *locus standi* had been refused by the Commissioners under a misapprehension because the Corporation of Edinburgh were opposing the order, and it was considered that the Corporation of Edinburgh covered the lessees. With regard to the contention as to the approval of the Board of Trade being requisite, as a matter of fact the District Company were the lessees, and they were working the whole of the tramways in Edinburgh. If the approval of the Board of Trade were necessary, it could be had at any instant. Under a section of another Act, however, they had perfect power to enter into a lease. That was the Act of 1897, which over-rode the general statute, because it was subsequent legislation. The tramways had been inspected by the Board of Trade, and the petitioners were paying £90,000 a year for the use of them. The committee after a brief consultation allowed a *locus standi* to the Edinburgh and District Tramways Company. Several witnesses were then called, and in the course of the proceedings Mr. Balfour Browne submitted a clause for the consideration of the committee, the effect of which would be to transfer the obligations as to running omnibuses between Golden Acre, Trinity, and Newhaven to the Corporation of Leith. The committee refused this amendment, and ordered the Bill to be reported without amendment. An application for costs was made on behalf of the promoters, but this was refused.

LIGHTING AND GENERAL.

Watford.—It is proposed to revise the price charged for public lighting.

Dundalk.—The Urban District Council will apply for an extension of their electric lighting order.

Stockport.—On last year's trading the electricity works made a gross profit of £4,568. 11s. 7d.

Cuckfield.—The Haywards Heath Electric Supply Company intend to apply for a provisional order.

York.—About £200 is to be expended during the holidays for electric lighting at the Fishergate School.

Hastings.—An enquiry has been held into an application for sanction to borrow £3,416 for electric lighting.

Halifax.—The Tramways and Electricity Committee are about to lay electric mains at an estimated cost of £117.

Beverley.—The Electric Power and Lighting Company, Limited, London, intend to apply for powers in the district.

Nelson.—Sanction has been received by the Town Council to the borrowing of £25,000 for electric lighting purposes.

Haywards Heath.—Two companies are anxious to secure the privilege of supplying the town with electrical energy.

King's Norton.—An expert is to be called in to report upon the electric lighting offers recently made to the District Council.

Golborne.—The Lancashire Electric Power Company intend to apply for a provisional order for electric lighting in the district.

Turton.—The Lancashire Electric Lighting Company intend applying to the Board of Trade for a provisional order for this district

Andover.—The Southern District Electricity Corporation are applying for a provisional order to supply electric light in Andover.

Coseley.—A provisional agreement has been drafted with Messrs. Whittaker Bros., of Dudley, for the electric lighting of the district.

Mirfield.—The agreement between the Council and the Yorkshire Electric Power Company for the supply of electricity has been signed.

Tottington.—The Lancashire Electric Power Company intend to apply for a provisional order for the supply of electricity in the district.

Tring.—The Empire Electric Light and Power Company intend to apply for a provisional order to supply electric light in the urban district.

Darlington.—The net profit on the electric lighting works has been £568. The amount will be placed to a depreciation and renewals account.

Carnarvon.—The Town Council have sealed the agreement with the National Construction Company to which we have already referred.

Macsteg.—The Council are negotiating with Mr. G. B. Fowler, Norwich, for the transfer of the Council's provisional order to a syndicate.

Malling.—The Rural District Council have declined to grant power for electric supply purposes in their district to the Kent Electric Power Company.

Frimley.—The Bournemouth and Poole Electric Supply Company, Limited, intend to apply for a provisional order this year for lighting the district.

Kingsbridge.—The electricity company intend to apply for a provisional order for supplying electric light to the town of Kingsbridge.

Dundee.—Mr. G. Balfour is to have an interview next week with the Town Council in relation to a proposed scheme of electrical supply for power purposes.

Camberley.—The Camberley Electric Supply Company and the Mutual Electric Supply Company intend to apply for provisional orders in the district.

Westhoughton.—We understand that the Urban District Council are about to put into operation the powers of their electricity provisional order of 1902.

March.—The Model Electricity Supply Company intend to apply for a provisional order or orders to supply electricity within the Urban District Council's area.

Matlock.—Messrs. Foot and Milne, Westminster, intend to apply to the Board of Trade for a provisional order to supply electricity within the Matlock area.

Holyhead.—Application is to be made for sanction to a loan of £1,750 for electric lighting. The acceptance of a conditional tender is noted in another column.

Sherbourne.—The Mutual Electricity Supply Company and the Southern District Electricity Corporation intend to apply for provisional orders in the district.

Dalkeith.—An offer of Messrs. Crompton and Co. containing terms for street-lighting and pumping water at Bridgend is before the Water Committee of the Town Council.

Knaresborough.—Messrs. Jeckell and T. P. Pollitt, of Manchester, intend to apply for a provisional order for introducing the electric light into Knaresborough and district.

Chorley.—It is intended to transfer the undertaking authorised by he Chorley Electric Lighting Order, 1898, to Mr. O. Hansom, electrical ngineer, of Fleetwood, Lancashire.

Skipton.—Mr. G. V. Fowler, of The Chestnuts, Warwick, intends to apply in due course for a provisional order enabling him to supply the Skipton urban district with electricity.

Bournemouth.—It is reported that the canvass for subscribers to municipal telephones has been very satisfactory, sufficiently good to warrant the Council going on with the scheme.

Barnet.—The North Metropolitan Electrical Power Company intend to apply for a provisional order authorising the company to supply electrical energy within the area of this authority.

Frome.—The Western Electric Distributing Corporation, Limited, intend to apply for a provisional order to supply electricity for public and private purposes within the area of the rural district.

Boston.—The Council have sealed an agreement with the National Telephone Company, Limited. A rent of 1s. per pole is charged, and the company are to remove all poles at six months' notice.

Wandsworth.—The County of London Electric Supply, Limited, are giving customers the option of an alternative flat rate of 6d. per unit for the supply of electric current for lighting purposes.

East Molesey.—The Mutual Electricity Supply Company, 11, Union-court, Old Broad-street, intend to apply to the Board of Trade for a provisional order to supply this district with electricity.

Clewer.—The Parish Council have consented to the intended application of the Windsor Electrical Company for an order for the supply of electrical power generally in the parish of Clewer Without.

St. Andrews.—The Electric Supply Corporation, Limited, have included St. Andrews in their scheme of operations, and it is stated that the erection of the works will be proceeded with forthwith.

Thrapston.—Mr. Edwin Percy Harvey, Richmond, Surrey, intends to apply for a provisional order for the supply of electricity within the Council's area. The Council have decided to oppose the application.

Kilkenny.—The Electricity Supply Corporation of Ireland, Limited, intend to apply to the Board of Trade for a provisional order to supply electricity for public and private purposes in the township of Kilkenny.

Tenbridge.—The electrical engineer in his last report states that two further applications for light had been received during last month, bringing the total up to 104 consumers, equivalent to 3,454 8-c.p. lamps.

Egham.—The Urban Electric Supply Company, Limited, intend to apply for a provisional order for the electric lighting of Egham. The Rural District Council are about to consult the County Council in the matter.

Longton.—In the electricity department the number of units generated during the month ending June 23 was 4,992, against 4,512 for the coresponding period last year, being an increase of 480 units, or 10 per cent.

Barnsley.—The electricity mains are to be extended to enable the Corporation to supply several residences on condition that the owners guarantee to pay the Corporation at least £25 per annum for a period of five years.

Bradford.—The Electricity Committee have recommended the Corporation to purchase 30,500 incandescent lamps required for free distribution to Corporation customers during the half-year ending Dec. 31 next.

Aston.—Extensions of mains have been authorised as follows: 1,180 yards of ·3 three-core cable, £553; 600 yards of ·12 three-core cable, £132. 10s.; 350 yards of ·3 three-core cable, to be laid in two-way 3in. ducts, £235.

Rye.—The Mutual Electricity Supply Company intend to apply for a provisional order authorising them to supply electricity within the borough. The borough do not propose to let the power to supply electric light go out of their hands.

Middlesbrough.—Sanction has been received to the borrowing of £19,900 for the extension of the electric light undertaking at Middlesbrough. The estimated profit during last month was £327, exclusive of interest on loan and sinking fund.

Morley.—The output from the electricity works during the month ending May 31 was 8,015 units, against 8,008 the same month last year. Sixty lamps were connected during the month, the total number connected to date being 11,733.

Portslade.—The Mutual Electricity Supply Company and the Hove and District Electricity Supply Company intend to apply to the Board of Trade for provisional orders authorising them to supply electricity within the Urban District Council's area.

Aspull.—Two years ago the Council applied to the Board of Trade for an electric lighting order. Twelve months ago the Board of Trade granted a further extension of the order for 12 months, and an application is to be made for another renewal.

Bishop's Stortford.—The Bishop's Stortford and Stansted Electric Lighting Company, Limited, and the Mutual Electric Supply Company intend to apply in November for a provisional order authorising them to supply electric light within the Council's district.

Farnham.—Messrs. Foote and Milne, Limited, the Farnham and District Electric Supply Company, Limited, and the Farnham Gas Company, Limited, intend to apply for provisional orders for the supply of electricity within Farnham urban district.

Swindon.—The last monthly report of the electrical engineer shows that the number of consumers connected on June 15 was 200, as against 195 a month previously. The number of street lamps converted to electric light was 135, as against 132 the previous month.

East Barnet.—The Empire Electric Light and Power Company, Limited, and Mr. G. Vaughan Fowler, The Chestnuts, Warwick, intend to apply for provisional orders to supply electricity within the East Barnet Council area. The Council will oppose the applications.

Sunbury.—The question of an exchange telephone connection with the National Telephone Company has been deferred for the present. Two electric light companies intend to apply for electric light orders for the district, but Edmundson's have practically obtained an order.

Sale of Plant.—The Dundee Town Council invite tenders for the purchase of a number of continuous-current Ferranti meters, which can be seen and full particulars given on application to the City Electrical and Tramways Engineer, Dudhope-crescent-road, Dundee.

Digitized by Google

Littlehampton.—A small committee has for some time been negotiating with the electrical engineer, Mr. Aylwin, who proposes to form a company for the electric lighting of the district. A maximum price of 5d. per unit for light and 3d. for power has been agreed upon.

Ludlow.—Notices of intention to apply to the Board of Trade for provisional orders to supply the borough with electric light have been received from Mr. William Norton, Ludlow; the Mutual Electricity Supply Company; Foote and Milne, Limited, London; and G. Vaughan, Warwick.

Harrogate.—The following resolution passed by the Council on June 13—namely, that the demand indicator tariff be reduced from 6d. and 3d. to 5½d. and 3d. per unit—has been rescinded, and the demand indicator tariff is to be altered from 5½d. and 3d. to 6d. and 2½d. per unit.

Ogwen.—The Portdinorwic electric lighting order has been approved. It embodies the use of overhead wires, on condition that the power is reserved to the Board of reveiwing the situation at the end of five years if they thought fit. The Council have decided to offer no observations upon the subject.

Tamworth.—The Rural District Council have been asked to consent to the Town Council's intended application for a provisional order authorising them to supply electricity for both public and private purposes within the parishes of Bolehall and Glascote and Wigginton in the rural district.

Edmundson's Electricity Co.—The directors have declared a final dividend on ordinary shares of 9 per cent. per annum for the half-year ended March 31, 1904, making, with the interim dividend of 5 per cent. already paid, a dividend of 7 per cent. for the year. Dividends will be paid on the 25th inst.

Limerick.—The Electric Lighting Committee have decided to allow special discounts to consumers as follows: less than 200 units per quarter, 2½ per cent.; not less than 200, 5 per cent.; not less than 400, 7½ per cent.; not less than 500, 10 per cent.; not less than 650, 20 per cent., if the accounts are paid within the quarter.

Caversham.—A letter from Mr. Warden-Stevens referring to the report as to electricity supply made by him last year, and desiring to know if the Council were disposed to consider making application for a provisional order in the coming session, is before the Highways and Lighting Committee of the Urban District Council.

Wealdstone.—The Mutual Electricity Supply Company intend to apply to the Board of Trade for a provisional order or orders to authorise them to supply electricity within the Council's area. An agreement with the Harrow Electric Light and Power Company *re* the extension of their mains to supply electricity to certain premises in the Wealdstone district has been sealed.

Promenade Concerts.—The tenth season commences at the Queen's Hall on Aug. 6, when nightly promenade concerts will be given until Oct. 21. A very complete list of artists who will work in conjunction with the Queen's Hall orchestra under the conductorship of Mr. Henry J. Wood has just been published. Mr. Robert Newman is the manager, as in former years.

National Telephone Co.—The directors, subject to final audit, recommend the following dividends for the half-year ended June 30, after payment of the dividends on the preference shares: at the rate of 6 per cent. per annum on the preferred stock; at the rate of 5 per cent. per annum on the deferred stock, less income tax in all cases, carrying £100,000 to reserve and about £9,000 forward.

Airdrie.—The Scottish House-to-House Electricity Company, Limited, intend to apply in November next for a provisional order empowering the company to transfer the order of the Airdrie Corporation of November, 1898, to some other company or person, along with their undertaking within the burgh of Airdrie. Mr. Kennedy has been asked to look after the Council's interests in the matter.

Mountain Ash.—The South Wales Electrical Distribution Company having applied for leave to carry their main through a portion of the Council's district, it has been decided to reply that the Council could not agree to the application, but that they would be prepared to receive terms from the company for lighting the district, the mains to be sufficiently low as not to be injured by the Council's traction engine, etc.

Cardiff.—In the estimate for furnishing the new town hall we note the following items: mayor's parlour—a 20-light electric pendant, £100; assembly hall—electrical fittings, £724; Council-chamber—electric pendants, etc., £480; town clerk's private office—electric fittings, £16; electrical engineer's private office, £98; chief constable's room—electric fittings, £30; assize courts (a number)—electric fittings, £187.

University College of North Wales.—In October next a systematic course of instruction in electrical measurement and practical electricity for students proposing to enter the profession of electrical engineer will be commenced. The physical laboratory is equipped with a compound steam-engine, continuous and alternating current (single and three phase) dynamos and transformers, secondary battery, and the most approved modern measuring instruments.

Wells.—The town clerk has been instructed to write to the Postmaster-General, and point out the delay occasioned in establishing telephonic communication in Wells and the district, and requesting that a canvasser be sent to get sufficient subscribers or a guarantee. It is stated that a call to Wells Fire Brigade to attend a fire at Shepton Mallet Prison, sent at 10.20 p.m., was not received at Wells, in consequence of their having no telephonic communication, till 11.20.

London County Council.—On Tuesday tenders were received for the supply, etc., of overhead cranes, electric jib cranes, and locomotives, etc., at the Greenwich generating station and wharf (London County Council tramways). These were referred to the committees concerned. It was agreed to lend the Poplar Borough Council £20,000 for electric light installation. Sanction was also given to the borrowing of £9,958 by the Shoreditch Borough Council for electric light installation and meters.

Gillingham.—The engineer's last report shows that 334 8-c.p. lamps have been connected to the mains since the June meeting, making a total of 11,064 8-c.p. lamps with 188 consumers connected, and that applications had been received for 327 8-c.p. lamps. A ·05 four-core distributor and a $^{7}/_{20}$ twin lighting cable are to be laid. The cable is in stock, and the resident engineer is to undertake all necessary cable work in future, and arrange with the borough surveyor for the necessary labour for excavations and paving.

Oulton Broad.—The Urban District Council have adopted a report by the Electric Lighting Committee stating that they are at present of opinion that arrangements can be made with the Oulton Broad Electricity Company, Limited, as to a provisional order, but before proceeding further asking the consent of the Council to obtain expert advice prior to giving any final recommendations. Incidentally it was stated that one or two experts had promised to give the Council advice for nothing when they were in the neighbourhood.

Norden and Bagalate.—The Lancashire Electric Power Company, Manchester, intend to apply for a provisional order authorising the supply of electricity in the Norden district for all public or private purposes. Messrs. Foote and Milne, Limited, of London, also intend to apply for a provisional order authorising them to supply electricity within the Council's area. It is understood that the Lancashire Electric Power Company intend to at once lay a cable through Heywood, Norden, Whitworth, and Bacup, and the District Council will endeavour to arrange a conference on the matter with other councils affected.

Torquay.—An equivalent of 125 8-c.p. lamps were connected during June, and there are two applications in hand, according to the electrical engineer's report. For extra time spent in preparation of drawings for the new electric station, the Council have granted £8. 4s. 6d. each to Messrs. C. Gilliard and H. Hooper. The borough surveyor and electrical engineer have been authorised to proceed with the preparation of the necessary plans and details for the extensions, referred to in our last issue, to enable application to be made for sanction to borrow the amount required as soon as the Royal assent has been given to the Dolter Tramways Bill.

Stock Exchange.—The Stock Exchange Committee have appointed July 20 special settling day for Metropolitan Electric Tramways, Limited, £350,000 4½ per cent. debenture stock, and July 27 for Marconi's Wireless Telegraph Company, Limited, further issue of 25,000 shares of £1 each, fully paid, Nos. 196,128 to 221,127. They have ordered Metropolitan Electric Tramways, Limited, £350,000 4½ per cent. debenture stock to be quoted in the official list. Applications have been made to the Stock Exchange Committee to grant a quotation to Madras Electric Tramway (1904), Limited, £50,000 5 per cent. debenture stock; and Urban Electric Supply Company, Limited, £200,000 first mortgage debenture stock.

Colchester.—Application will be made for a loan of £16,500 for various purposes, including mains extensions, £1,200; boiler, £750; condensing plant, £700; water-softening plant, £300; one 375-kw. 550-i.h.p. combined set, £2,200; one 550-i.h.p. high-speed engine, £1,360; house connections, meters, etc., £2,180; mains extensions under contemplation, £1,942; further main extensions, estimated up to 1906, £1,558; multitubular boiler and dynamos, £1,942; contingencies, £623. The committee have reported the following statistics: output in May, 1904, 20,258 units (1903, 17,825); consumers, 462 (358); 8-c.p. lamps connected, 25,206 (22,752).

Southport.—It is proposed to apply for sanction to borrow £20,000 in accordance with the following estimate: four miles high-tension cable and laying, £1,584; 1,000 cast-iron pipes for crossing streets at 7s., £350; 12 30-kw. transformers at £60, £720; four watertight transformer tanks at £15, £60; two sub-stations and switchgear at £360 each, £720; services and meters at £2 000 per annum, £6,000; low-tension mains at £2 000, £6,000; line booster (500 amperes 50 volts), £250; battery, £1,300; automatic reversible battery booster, £400; battery-room, £300; switchboard extensions, £50; equipment of meter-testing room, £150; six mechanical stokers, £479—£18,363; contingencies, £1,637.

Camberwell.—An application from the Blackheath and Greenwich District Electric Light Company, Limited, the successor to the Crystal Palace and District Electric Supply Company, Limited, giving notice of intention to lay a $^{37}/_{15}$ low-tension concentric lead-covered cable from the north-east corner of Westow-hill and Crystal Palace-parade, along the west side of the parade to Farquhar-road, then along the southern and western side of Farquhar-road to its junction with Jasper-road (at letter-box), where the cable will cross the road and continue along the east side to the junction of Farquhar-road and Dulwich Wood-park, has been agreed to. The Council will support any application made to Parliament for the purpose of obtaining powers to enable the councils of metropolitan boroughs to wire and fit consumers' premises for electric lighting, and to obtain loans for so doing.

London Gazette.—The Electric Extension Company, Limited, will be wound up voluntarily. Mr. C. E. Ruckley has been appointed liquidator. The capital of the British Aluminium Company, Limited and Reduced, is now £310,000, divided into 10,000 "A" cumulative preference shares of £10 each, 20,000 preference shares of £10 each, and 10,000 ordinary shares of £1 each, instead of the capital of £400,000, divided into 10,000 "A" cumulative preference shares of £10 each, 20,000 preference shares of £10 each, and 10,000 ordinary shares of £10 each. The *London Gazette* of the 8th inst. publishes a table of rates for foreign and Colonial telegrams, which came into operation from the 1st inst. Mr. Harold de Vaux Brougham, liquidator in the estate of the Electric Lamp Regenerating Company, Limited, 3, Crown-court, 62, Old Broad-street, London, has been released from July 7.

Digitized by Google

Battersea.—Electric mains (including arc light leads) are to be extended from Northcote-road along Bramfield-road to Ashness-road, at an estimated cost of £142. 5s. 7d.; and an electric supply service laid from a point in Nightingale Park-crescent to 19, Blenkarne-road, at an estimated cost of £24. The following particulars relative to applications for the supply of electrical energy to premises within the borough, including the Council buildings, appear in the last report: Quarter ended June 14, lighting, number of applications 638, March 15, 569—increase, 69; actual consumers, 589 (534) + 55; electrical energy equivalent in 8-c.p. lamps, applied for, 47 385 (43,172) + 4,213; actually supplied 41.085 (38.361) + 2,724; motive power—applied for, 638¼ h.p. (585¼ h.p.) +53 h.p.; actually supplied, 450⅛ h.p. (418⅛ h.p.) + 32 h.p.

Edinburgh.—The electric lighting accounts for the past year are eminently satisfactory. The revenue was estimated at £108 835; the actual amount has turned out to be £116,178. The expenditure was estimated at £94 660, but it has been kept at £92,181. The estimated balance available for appropriation at the close of the year was £14,175; the actual was £23,997. The maximum to which the reserve fund might be built up on the present capital expenditure is £84,000. At the present moment it amounted to £43.000, so that the balance of £24.000 would bring the fund up to £67,000, and in the present year the Electric Light Committee estimates that, after reducing the price of the electric current, there would be a balance available for appropriation at the close of the year of £17,000, which, apart from the accumulations of interest on the reserve fund investments, would virtually bring the reserve fund up to its maximum at this time next year.

Newport (Mon.).—The report of the Electricity and Tramways Committee, which was adopted on Tuesday, deals with the proposed addition to the generating plant in order to meet the demands for current for power and lighting purposes. The scheme provides for an additional 300 kw. of high-speed plant, together with a battery at Corporation-road station, thus enabling the Highfield boosting plant to be used, giving a net increase of 500 kw. to the lighting and power portion of the plant. The estimated cost was £8,200. New high-tension feeders are to be laid in certain districts, and two new sub-stations constructed at a cost of about £1,900. In connection with the low-tension supply new feeders and cables are to be laid and switch-gear obtained for Llanarth-street and the sub-stations at Maindee, and a balancer is to be fixed at Llanarth-street. This is estimated to cost about £4 725, with an additional £3,000 for cable work that might be required in places not yet specified. The application which will be made will amount to £17,825.

Sunderland.—It will be remembered that recently the Corporation failed to enter an appearance when the petition by them against the Sunderland district electric lighting order was being heard by a committe of the House of Lords, and the Corporation were ordered to pay the costs of the proceedings, amounting to over £500. The Electricity and Lighting Committee, in the report upon the matter at Wednesday's meeting of the Council, explained that they were advised that opposition in committee would have little chance of success, and they decided to instruct their parliamentary agents not to proceed further. No appearance was therefore entered. The agents stated that the ordinary and regular practice was followed on behalf of the Corporation, and that the action of the House of Lords is not precedent, irregular, and in excess of their jurisdiction. They caused application to be made for the Corporation to be heard upon the matter with a view to the reversal of the order. That application having been refused, the committee are now arranging for proceedings in the House of Lords to the same effect.

Aldrington.—The Brighton and Hove Councils have come to the following agreement: "The Hove Corporation to take all the electricity required by them for the supply of or use in the parish of Aldrington, at the rate of 4½d. per unit for the first 365 hours' use of the maximum demand, and 1½d. per unit afterwards, such electricity to be at low tension at 440 volts. The Hove Corporation to have the option on giving six months' notice, expiring on June 30 or Dec. 31, in any year of taking future supply for the remainder of the period of the contract, at the price of 5d. per unit for first 365 hours' use, and 1d. per unit afterwards. Contracts to be for nine years—*i.e.*, to expire Dec. 8, 1913, or such other date about that time on which the Hove Corporation have power to take over the Hove Company's undertaking. The Hove Corporation to carry out the supply of electricity in accordance with the terms of the Aldrington electric lighting order and any regulations of the Board of Trade made thereunder. The Brighton Corporation to be empowered to disconnect the supply in the event of such terms and regulations not being complied with, but only during such period as the default continues."

Islington.—The Borough Council have petitioned against the Supply of Electricity Bill. At to-night's meeting it will be proposed: "(*a*) That the London County Council be informed that the Islington Borough Council are in favour of the renewal of the application for parliamentary powers to enable metropolitan borough councils to wire and fit consumers' premises for electric lighting and to obtain loans for the cost of the work, and that they will support any Bill that may be introduced into Parliament for this purpose. (*b*) That the metropolitan borough councils who are electric lighting undertakers be informed that the Council are prepared to support the application in question, and that they be asked to take similar action." The borough treasurer's report of the electric enterprise for the year ending March 31 last shows that while in March, 1903, there was a deficit of £1,496, there is now a debt owing from the Council of £1,656. The present success is said to be largely due to the use of the day load for purposes of motors in factories. Last year the supply went up to 289,894—an increase of daylight supply of 213,221 units. The revenue of the year was £48,436—an increase on the year of £4,009; whilst the expenditure shows a decrease of £304. The number of additional consumers was over 200. Making allowance for interest on loans, there is a net surplus of £1,218. That is, if the undertaking were in the hands of a company, the earnings would represent a dividend equal to 3·6 in the £.

Manchester.—A deputation from the New Mutual Telephone Syndicate waited upon the Lord Mayor on Tuesday. Mr. W. Thomson, chairman (*pro tem.*) of the Mutual Telephone Company, described the several proceedings subsequent to the first effort to produce a municipal competitive telephone system in Manchester 8½ years ago, when the Corporation of Manchester was asked to join the Glasgow Corporation in applying to the Postmaster-General for power to produce municipal telephone exchanges. The position now, he said, was somewhat altered by the recent declaration of the present Postmaster-General that he proposed to try to purchase the undertakings of the National Telephone Company this year. This declaration, it was understood, stopped for the moment the Telephone Committee from going on with their municipal telephone scheme, and it was felt that the Corporation should without further delay arrange to meet the liabilities which had been incurred by the New Mutual Telephone Syndicate, otherwise a serious injustice would be done to the members of the syndicate. The work of the syndicate in Manchester had proved of great value to the mercantile community in compelling the National Telephone Company greatly to improve its system, and it was largely due to the syndicate that the right to produce municipal telephony became possible. The Lord Mayor, in reply, promised to convey the views of the deputation to the proper quarter.

Wimbledon.—The accounts of the Urban District Council's electric lighting undertaking for the year ending March 31 last give the following particulars of the trading since the installation was first laid down by the Council: existing debt, £110,312; income, £18,640; expenditure, £16,699; loans, £1,940. In 1903 a reserve fund was started with £500, and in the year ending March last £1,000 was added to the reserve. The repayment of principal has increased from £135 in 1899 to £2,992, the payments for interest from £114 to £3,155, and the working expenses, which in 1900 were £2,322, rose last year to £9,552. The amount actually borrowed from the start totals £120,130, and sanction has been received to borrow a further £8,872. The cost of generation per unit sold was 1·201d., coal and other fuel (including carriage and other expenses) costing only ·92d. per unit. Cost of distribution works out at ·005d.; repairs and renewals of public lamps, ·134d. per unit; rents, rates, and taxes, ·148d.; management expenses, ·281d.; law and parliamentary charges, ·012d.; and special charges, ·019d.—making the total works cost 1·88d. per unit. Repayment of principal and interest on loans, payment to reserve fund, and other expenses absorbed 1·236d. per unit. The total cost of each unit sold was 3·116d. The sale of current for private lighting brought in £12,111, of which £5,641 was derived from current sold at 7d. per unit, £2,802 at 5d., £691 at 4½d., £905 at 4d., £171 at 3½d., £136 at 3d., and £1,762 at 2d. per unit. Sale of current under contracts brought in £11, and for public lighting £5,984 was received. The rent of meters amounted to £535.

Beckenham.—The Urban District Council have approved of a report in which the Electric Lighting and Tramway Committee stated: "A communication from the British Insulated and Helsby Cables, Limited, offering to pay 4 per cent. on any further free wiring expenditure as from the date of the expenditure and during the continuance of their lease was submitted. The committee recommend that funds up to maximum of £5,000 be provided for extending the free wiring, that a loan of this amount be included in the scheme for the equation of loan payments, and that the question of raising the necessary money by instalments be referred to the Finance Committee. A letter was read from the Board of Trade approving of the transfer of the Crystal Palace District Electric Lighting Company to the Blackheath and Greenwich Electric Lighting Company. A plan was also submitted of the company's intention to lay mains in the Beckenham district. One of these mains appears to be for the urban district of Penge and the other for improving the system of supply to the Crystal Palace district of Beckenham. As to the latter, the committee, in view of the Council's notice to purchase already served, very strongly object to the expenditure, and they recommend the Council to take the necessary steps to give effect to this objection. With a view to encourage the purchase of free-wiring installations by consumers, the Council is recommended to sell free-wiring installations at the contractor's charges plus 5 per cent. (instead of 10 per cent. as hitherto) for supervision, etc. An application for an increase in the price for trenchwork on extension of mains and services was submitted. The committee cannot recommend the Council to accede to the application. It was referred to the surveyor to report as to providing a bath for the use of the men working on the dust destructor."

St. Pancras.—On Wednesday the following motions were considered: (1) "That the resolutions of the late vestry on April 11, 1900, fixing the following charges for the supply of electric current, be and are hereby rescinded—viz.: (*a*) for supply to consumers not using the maximum demand indicator, 5d. per unit; (*b*) for supply to consumers for motive power, heating, etc., 2d. per unit; (*c*) for supply of electric current to public street lamps, 3d. per unit, and a special charge of £250 for keeping certain lamps in lighting throughout the night." (2) "That the resolution of the Council of May 8, 1901, fixing the charge for supply of electric current by the maximum demand indicator system after the first hour at 3d. per unit, be and is hereby rescinded." (3) "That, in place of the existing charges rescinded, the following charges for supply shall come into operation commencing with the present (September) quarter: (*a*) For lighting purposes—by the maximum demand indicator system, 6d. per unit for the first hour and 1½d. per unit after; customers not using the maximum demand system at a flat rate of 4d. per unit; supply to buildings, 3d. per unit. (*b*) For power purposes—1d. per unit. The foregoing charges to apply only to consumers who are supplied at the pressure of 220 volts or 440 volts and also to consumers who agree to change from the 110 volt pressure of supply to the higher voltage when required by the Council. They shall not apply in the case of

Digitized by Google

Messrs. Price and Reeves, the contractors of the Charing Cross, Euston, and Hampstead Railway, until such time as they have taken the minimum of 1,000,000 units in accordance with the contract entered into with them. (c) Public street-lighting—1½d. per unit. and the general fund to take over the capital liability of £4,311. 1s. 2d. now borne by the electricity fund, and to pay, in addition to the 1½d. per unit for current, the charges for labour trimming, repairs, carbons, and maintenance.

Fulham.—On Wednesday the Electricity Committee reported as follows: "In April last the borough electrical engineer submitted a report recommending the Council to undertake an extension of its electric lighting undertaking, involving a considerable expenditure, and pointing out the necessity for taking immediate action, with a view to making provision for the coming winter season. After careful consideration we then recommended the Council to order a 750-kw. turbo-alternator, at an estimated cost of £7,000, as a first urgent instalment of the proposed extension, and instructed the borough electrical engineer to prepare for our further consideration a comprehensive scheme dealing with probable future requirements for the next five years, so that the extension recommended might form part of a well-considered scheme which would be carried out from time to time as necessity required. The borough electrical engineer has now submitted reports dated June 4 and July 1, 1904 (copies of which have been circulated amongst the members of the Council), and plans giving particulars of a scheme, which he is of opinion it will be found necessary to carry out in sections during the next five years at a total estimated cost of £129,000—viz.: first section, £42,000; second section, £32,000; third section, £25,000; mains, sub-stations, etc., £10,000; house connections, meters, etc., £20,000. The first section, which he recommends should be authorised at once, comprises the following—viz.: one 750-kw. turbo-alternator (already ordered), £7,000; one 1,000-kw. Belliss set, complete with condensers, pumps, etc. (to be ordered), £8,947; one exciter set, £500; switchboard additions, £500; four boilers with accessories, £4,340; coal bunkers, elevators, etc., £2,230; economisers, £1,075; boiler pumps, £250; wiring motors, etc., £200; condenser, steam, and other pipes, £3,000; condenser, sump, and river work, £2,000; chimney, £4,000; boiler-house buildings and alterations, £7,500; contingencies, £500; for connections, £6,000; extra buildings, £4,000—£52,042; less already sanctioned by the Council, £7,000—£45,042."

Wolverhampton.—The report of the Electric Lighting Committee shows a gross profit of £11,495. 7s., equal to 8·30 per cent. on the capital expenditure (averaged) during the year. Out of this amount the following charges have to be met, on capital expenditure (averaged) during the year: interest (less interest received), £3,839 (2·80 per cent.); sinking fund, £4,981 (3·50 per cent.)—£8,720 (6·30 per cent.); balance, being net profit for the year, £2,775 (2 per cent.)—£11,495 (8·30 per cent.). The committee express the opinion that this result of the past year's working is satisfactory in all respects, and indicates that the undertaking is in a sound financial condition, and that this result was especially gratifying in face of a very substantial reduction which was made in the price of current for lighting purposes during the period covered by these accounts, and a large reduction in respect of the charges for public street-lighting, the actual reduction in revenue from this cause being over £1,400. The committee are pleased to be able to report a continuous diminution in the cost of production, the expenditure on the generation and distribution of electricity—inclusive of all management charges, but exclusive of capital charges—being actually less for the year ending March 31, 1904, than it was for the preceding 12 months, although the output of electricity has increased by over 21 per cent. During the past year the output of electrical energy to private consumers for motive power has increased by 55 per cent., and the committee have every reason to believe that this rate of increase will be proportionately maintained. The comparison shows the continued growth of the undertaking, and, although a considerable percentage of the total increase in units sold is in respect of electrical energy supplied to the tramways company, yet it will be seen that the percentage increase in units sold to private consumers is also of a very satisfactory character. Number of consumers, 1904, 739 (1903, 655)—increase, 13·0 per cent. (20·2); number of lamps connected, 64,382 (54,578)—increase, 18 per cent. (30·5); units sold, 1,971,794 (1,624,639)—increase, 21·4 per cent. (17·0).

Hereford.—Sanction has been received to the borrowing of £1,100 for the completion of the electrical installation at the Burghill Asylum. The sanction issued by the Board on Nov. 25 last, authorising a loan of £550 for the same purpose, has been cancelled. The Electric Lighting Committee's report shows that the surplus profits for 1902-3, after paying interest, amounted to £673. 7s. 5d.; the repayment of principal was £920, leaving a balance of £246. 12s. 7d. to fall upon the rates. For 1903-4 the surplus profits were £815. 1s.; the repayment of principal was £1,000, a balance of £184. 19s. thus falling on the rates. The financial results of the undertaking for the year ended March 25, 1904, are as follows: Total units sold, 128,100, as compared with 108,815 units sold in 1902-3. Of these there were charged at 6d. per unit, 92,738 units, realising £2,318. 9s.; at 4d. per unit, 17,509 units, realising £291. 16s. 4d.; at 3d. per unit, 9,688 units, realising £121. 2s.; at 2d. per unit, 9,165 units, realising £68. 0s. 10d; sundry receipts, £3. 9s. 6d.; less discounts and irrecoverables, £271. 18s. 9d.; meter rents, £117. 17s. 2d.; sundry receipts, £23. 19s. 7d.—total, £2,672. 15s. 8d. The working expenses for the year, including wages, salaries, oil, stores, coal, repairs, taxes, etc., were £1,222. 15s. 6d.; interest, £634. 19s. 2d.—total, £1,857. 14s. 8d., leaving a profit toward repayment of capital (£1,000) of £815. 1s. The committee submit a return showing the output of current for the year ended March 25, 1903, and March 25, 1904, as follows: units sold for lighting during the year ending March 25, 1904, 110,247, against 95,213 the previous year; units sold for power 17,855, against 13,602; total units sold 128,100, against 108,815; equivalent number of 8-c.p. lamps at beginning of year 9,372, against 8,257; 8-c.p. lamps added 1,528, against 1,115; equivalent number of 8-c.p. lamps at end of year 10,900, against 9,372; number of arc lamps connected 22, against 20; number of motors connected 17, against 13; horse-power of motors connected 50¼, against 42. The committee have examined the estimate of income and expenditure on the electric light works for the current year as follows: estimated expenditure, £3,046; estimated income, £3,030; balance to be provided, £16.

Hammersmith.—Mr. G. G. Bell, the electrical engineer to the Hammersmith Borough Council, in his report upon the annual accounts of the electricity works for the year ending March 31 last, states that the accounts being made up to the last Thursday in March, this year includes 53 weeks instead of 52 weeks. Meters were, however, read as near as possible to the same date as formerly, so the cost sheets are charged one week extra without any corresponding increase in the revenue. He particularly draws attention to the fact that the cost of fuel has actually decreased £21 when compared with the previous year, in spite of the fact that 487,084 more units were sold, producing an increase of revenue amounting to £5,546. Repairs and maintenance have also decreased, owing to the fact that last year this account was debited with a certain amount of work which has this year been charged as "special charges." The increase shown in management expenses is principally due to the fact that the salary of the station superintendent has been charged under this heading instead of to wages as formerly. After deducting special charges (£2,071, not incurred in the actual production of current) the total costs amounted to £17,204, as against £16,254 for last year, but credit should be taken for the special charges and work done and goods supplied to consumers and others which had nothing to do with the cost of working the department. After deducting these items from both accounts, the cost of generating and distributing electricity was £15,793 for last year, and £16,035 for the year under review, or an increase of only £242 for 487,084 extra units sold. With regard to the special charges—£2,071—this expenditure is set out in detail. Strictly speaking, these should not be charged to revenue account, being works of a permanent nature in the generating station and elsewhere, but owing to the fact that for a portion of the expenditure they had no power to obtain loans, whilst the other portion would probably mean some difficulty in obtaining loans from the London County Council, it was considered advisable to discharge them direct out of current revenue, and not burden capital account, particularly as they did not increase the capacity of the station for supplying current. Interest had increased from £5,335 to £5,925, or £590 more, whilst the redemption of loans had increased by £1,089—from £4,514 to £5,603—being 2·8 per cent. of the capital outlay at the end of the year. This was the highest percentage of any metropolitan municipal undertaking, but was still insufficient to allow for the actual depreciation of the plant. Mr. A. G. Kean, the borough accountant, in his report says: "On capital account, the amount of capital borrowed for the purposes of the undertaking remains the same as at this time last year — viz., £196,311—as no new loans have been taken up during the year. During this period debt has been redeemed to the extent of £5,603, the unpaid capital borrowed at end of year being £176,168. The total capital redeemed to March 31 last was £20,143, being a percentage of 10·26 on the amount of loans taken up. The revenue account has much increased during the year, the gross income being £32,725. 5s. 5d., whereas at the corresponding date the income was £27,185. The greater part of this increase is accounted for by the expansion of revenue from private consumers, including the users of power, the increase of income for maintenance of public arc and incandescent lighting being £94 only. The working expenditure for the year has been £19,276, thus leaving a gross surplus of £13,449—a sum which, after allowing for irrecoverables, etc., and providing for an adequate reserve, would, in the case of a private company, be available for distribution to shareholders as dividend. The gross profit represents a percentage of 6·7 upon the amount of capital expended on the undertaking. Last year the gross profit was 5·74 per cent. upon amount of capital expended. After meeting charges of interest on indebtedness and redemption of capital, the net profit for the year was £1,855, the corresponding sum last year being £1,063. This net profit is equivalent to ·92 per cent. on the amount of capital expended, whilst the percentage last year was ·55. This net profit has been made after charging to the year the cost of certain works of a permanent nature. The total cost of these works amounts to £2,071. 18s. A reserve fund of £2,500 has been formed, but as this sum is not invested, it would not be immediately available in the case of any sudden emergency or breakdown of machinery, etc." He suggests the advisability of investing the same in Consols. Apart from this reserve, the accumulated balance now standing to the credit of the scheme was £3,169.

Croydon.—A further sum of £20,000 is to be raised for the purposes of extension of mains. Twenty-five applications were received during June, being equivalent to 963 8-c.p lamps. Eighteen consumers were connected, being equivalent to 694 8-c.p. lamps, and 925 yards of mains extensions carried out. The engineer (Mr. Alex. C. Cramb) has reported on a suggested system of charging for current for power and other purposes during the period of light load. He said it would be apparent that if a demand for electric supply could be created during the hours when the lighting load was not on the station, this demand could be supplied with the existing machinery at a very low rate. He was of opinion that a charge of 1½d. per unit during the hours of light load would well pay the department, and therefore submitted the following scheme. Taking the hour of dusk and 11 p.m. as being the hour at which the lighting demand falls off, he recommended that the charge for current should be 1½d. per unit for all times except between dusk and 11 p.m. During the time between dusk and 11 p.m. consumers should have the option

Digitized by Google

of being charged at the rate of 5d. per unit for all current consumed during this period, or, alternately, the supply should be cut off for this time. By means of a time switch set once a month the relative hours during which the two rates were charged could be predetermined. In the case of those consumers who wish to have a supply available during the hours at which the higher rate (5d. per unit) was charged, the time switch would be arranged to pass the electric current through a second meter. In the case of those consumers who did not require a supply between dusk and 11 p.m. he suggested that the following rentals be charged for the time switches: for motors up to 5 b.h.p., £2 per annum; for motors above 5 b.h.p. up to 10 b.h.p., £2. 10s.; for motors above 10 b.h.p. up to 20 b.h.p., £3; for motors above 20 b.h.p., £4 per annum. As the demand for electric light on Wednesdays and Sundays was much less than on other nights of the week, the time switches would be arranged so that the higher rate would not be charged on these two days of the week. The revenue from current for motive purposes for last year amounted to about £524. Should all the present consumers elect to be charged on the first scheme herein set forth—viz, at 1½d. per unit—the revenue would amount to £360, or a reduction in revenue of £264. He estimated that this drop in revenue would be more than compensated for within a short time, and suggested that the fact of the Corporation being able to supply electrical power at a low figure would be of considerable assistance to many small men of business, and in conjunction with the motor hiring scheme a very considerable increase in the demand for electrical power in the borough might be anticipated. With respect to the hiring of motors, the engineer recommended that agreements be entered into with motor manufacturing firms for the hire-purchase and hiring of motors to prospective consumers in the borough. He received offers from a number of firms in the country based on specifications and certain proposed agreements issued to them, but owing to the fact that there were two systems of supply in the borough, it was found necessary to obtain prices for both direct and alternating current motors, and he found that separate agreements would have to be made with two different firms for the respective supplies. He recommended that the offer of the Lancashire Dynamo and Motor Company, Limited, for the supply of direct-current motors be accepted. Under this arrangement motors could be (1) purchased for cash, (2) taken on either three or four years' hire-purchase, or (3) simple hire for 12 per cent. per annum of value of motor. With regard to the motors for the alternating-current area, he was unable to make a definite recommendation at the present moment, but hoped to do so at the next meeting. The Corporation under this proposed scheme take no financial responsibility. The recommendations were adopted last week. The report of the seventh year of working by the borough electrical engineer contains the following: The returns show a net profit, after providing for sinking fund and interest, of £6,754, being an increase of £2,099 on that for the previous year. The capital expenditure during the year has amounted to £36,843, increasing the total capital expenditure of the undertaking to £271,258. The total receipts for the year amount to £46,596, as compared with £40,157 for the previous year, and the total expenditure amounts to £25,538, as compared with £21,889, leaving, after carrying £58 to next account, a gross profit to be carried to the net revenue account of £21,000, as against £18,200. Interest on stock, sinking fund, etc., amounts to £14,246, and the return on the average capital outlay represents 8·36 per cent. The price obtained for private supply is 4·17d. per unit, as compared with 4·34d. per unit for the previous year. The average price obtained for public lighting amounts to 2·69d. per unit. The number of consumers connected has increased during the year from 1,378 to 1,721, and the number of lamps connected from 96,479 to 115,461. The total number of units generated during the year amounted to 4,463,343, as compared with 3,889,794, being an increase of 573,549 units. The total number of units sold during the year amounts to 3,663,248, as against 3,131,841 for the previous year, being an increase of 16 per cent. The percentage of units sold to units generated amounts to 81·4 per cent. for the present year, as against 80 per cent. for last year. The number of units sold for tramways shows an increase of 12·5 per cent.; private supply, 26·1 per cent.; public lighting, 4·1 per cent. The mains laid during the year amounted to 12 miles, making the total length of cable laid in the borough 162 miles. During the year there have only been two breakdowns on the mains; each of these has been traced to external damage from picks. It is hoped that during the coming year a reduction will be made in the cost per unit generated in that part of the system which deals with the general supply.

PROVISIONAL PATENTS, 1904.

JULY 4.

14933. An improved mode of protecting life from the "live rail" danger on electric railways. Henry Curwen, 32, Sidney-grove, Newcastle-on-Tyne.

14940. An electric time switch. Arthur Joseph Parsons and Harold Mandefield, 67, Goodramgate, York.

14986. Improvements in actuating magneto-electric igniters of explosion motors for cycles and other vehicles. Ludwig Zeidler, 40, Chancery-lane, London.

JULY 5.

15011. Improvements in primary batteries. Frank Richmond, 254, Colne-road, Burnley, Lancs.

15034. Improvements in electric arc lamps. Crompton and Co., Limited, and Arthur John Hodgson, Arc Works, Chelmsford.

15035. Improvements in instruments for the measurement of electrical resistances. Kenelm Edgcumbe and Edgar Isaac Everett, 151, Great Saffron-hill, London.

15041. Improvements in means for signalling to and communicating with telephone exchanges. Gustav Ellis, 60, Queen Victoria-street, London.

15043. Improvements in electric transmitters. Henry Harris Lake, 70, Southampton-buildings, Chancery-lane, London. (Submarine Signal Company, United States.) (Complete specification.)

15046. A system for recording the number of telephone messages. Horace Stanley Williams, 7, Southampton-buildings, Chancery-lane, London.

15054. Improvements in and relating to apparatus employed in connection with electric telephones. William Walker, 18, Southampton-buildings, Chancery-lane, London.

15067. Improvements in electric arc lamps. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

15068. Improvements in electric arc lamps. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

15069. Improvements in fluid-pressure governors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

15070. Improvements in and relating to the control of electric motors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

JULY 6.

15117. Improvements in electric cut-outs. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

15118. Improvements in dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

15131. Improvements in electric railways or tramways. Walter Ffrench Gibbs, 23, Southampton-buildings, Chancery-lane, London.

15155. A new or improved automatic electrical balance. Wincenty Dworzynski, 18, Buckingham-street, Strand, London. (Complete specification.)

JULY 7.

15199. A new or improved device or apparatus for fixing electric lamps in the sockets of overhead electroliers, brackets, and the like, or for detaching them therefrom. William Veasey Bigge, 111, Hatton-garden, London.

15203. Electric burglar and fire alarm. Carlo A. Ali, 37, Chancery-lane, London. (Complete specification.)

15226. Improvements in the method of selecting electrical impulses. Daniel Watts Troy, 18, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, July 11, 1903, being date of application in United States.) (Complete specification.)

15230. Improvements connected with electric arc lamps. Louisa Calvert and William Arthur Snape, 173, Fleet-street, London.

JULY 8.

15253. Improvements in dynamo-electric machines and motors. Wilfred Robert Vernet Marshall, 121, West George-street, Glasgow.

15255. Improvements in omnibuses, horse cars, electric cars, and the like. Hartley Illingworth, The Old Bank, Tadcaster, Yorks.

15258. Improvements in electromagnetic switch devices for telephone stations. Paul Arnheim, 65, Chancery-lane, London. (Date applied for under Patents Act, 1901, July 20, 1903, being date of application in Germany.) (Complete specification.)

15261. Improvements in dynamo-electric machines. William Arthur Ker, 65, Chancery-lane, London.

15267. Improvements in electric light fittings. John George Irving, Temple buildings, Albert-street, Nottingham.

15288. Improvements in the handles of spanners, pliers, and other tools used in electrical work. Henry Dorning Bailey and Percival Ormond Bonniwell, 65, Chancery-lane, London.

15289. Improvements in relays for direct-current automatic circuit breakers. Charles Cornfield Garrard and Ferranti Limited, 18, Southampton-buildings, Chancery-lane, London.

15290 Improvements in electrical measuring instruments. Charles Cornfield Garrard and Ferranti Limited, 18, Southampton-buildings, Chancery-lane, London.

15294. An improved process of electro-depositing antimony Anson Gardner Betts, 7, Southampton-buildings, Chancery-lane, London.

15296. Improvements in electric elevators. Robert Edward Phillips, 70, Chancery-lane, London. (Ernest Henry Vogel, United States.) (Complete specification.)

15298. An improved process of treating the metal mixtures produced as a by-product in electrolytic metal refining operations. Anson Gardner Betts, 7, Southampton-buildings, Chancery-lane, London.

15300. Improvements in electric transformers. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

NOTES.

Institution of Electrical Engineers.—The following are the names of the gentlemen who have been appointed by the Institution as delegates to attend the International Electrical Congress to be held at St. Louis: Mr. R. Kaye Gray, president; Colonel R. E. Crompton, C.B., past-president; Prof. John Perry, F.R.S., past-president; Dr. R. T. Glazebrook, F.R.S., member of council; and Mr. H. E. Harrison, B.Sc., B.A. Mr. W. Duddell will act as hon. secretary to the delegation. The two last-named gentlemen have previously served on the Council of the Institution. The congress will open on Monday, Sept. 12, and will meet daily until Friday, the 16th.

Copper Production.—The output of copper during the year 1903 amounted to 565,820 long tons, being an increase of 24,525 tons over the previous year. With two minor exceptions, all the copper-producing countries showed an increase. The great bulk was obtained in North America, the produce there amounting to 64·7 per cent. on the whole, the United States being credited with 53 per cent. In the aggregate Europe yielded 16·5 per cent., Spain and Portugal being the most prolific countries. Asia, as represented by Japan and Australasia, contributed 10 7 per cent. South America produced 7·1 per cent., the greater portion of which was obtained in Chili.

New Publications.—"An Enquiry into, and an Explanation of, Decimal Coinage and the Metric System of Weights and Measures," by E. Anthony (Anthony Bros., Limited, Hereford); "Magnetism and its Elementary Measurement," by W. Hibbert (London: Longmans, Green, and Co. 2s.). A volume entitled "The Telephone Service: Its Past, Present, and Future," by Mr. H. L. Webb, which is to be published shortly by Messrs. Whittaker and Co., will doubtless be read with interest in view of the present discussion on the telephone question. This work will be an endeavour to describe in plain language the general features of a modern telephone exchange, and it is hoped that it may be of assistance to the telephone user and others interested in the working and development of the telephone service.

The Government and Wireless Telegraphy.—The Wireless Telegraphy Bill introduced by Lord Stanley, which passed its first reading in the House of Commons on Monday, proposes to give the Post Office power to regulate wireless telegraphy, but does not confer a monopoly, as it was freely reported to do, upon the Government. Under the terms of the Bill the Post Office is to be empowered to deal with wireless telegraphy by license, in order to ensure that in time of national danger the Government will be in a position to take over, suppress, or make use of all wireless telegraphs, so as to be of assistance to themselves and to prevent their being of assistance to the enemy; and also to protect stations from being interfered with by the erection of rival stations in the neighbourhood. Special provision is made for experimental installations. The Bill is drawn in very concise terms, and must pretty well constitute a record in point of brevity.

Carbon Vaporised in Incandescent Lamps.—In a paper recently read before the French Academy of Sciences, Prof. Berthelot examines, at the lowest possible temperatures, the state of the vaporised carbon produced in the vacuum of incandescent lamps from the amorphous carbon of the filaments, comparing it with such well-known allotropic modifications of carbon as the diamond graphite amorphous carbon. The main results of this investigation, as described in the *Scientific American*, are that carbon gives off an appreciable vapour tension at a temperature not exceeding 1,500deg. C., this tension being so low as to require several hundreds of hours to produce some milligrammes of condensed carbon, even in the nearly absolute vacuum of electric lamps. On the other hand, the carbon thus vaporised at the lowest possible temperatures is, under Prof. Berthelot's experimental conditions, amorphous carbon without any addition of graphite or diamond. The temperature at which a vapour tension of carbon may be noted appears from this to be about 2,000deg. below the boiling point, which, according to Prof. Violle, is 3,600deg. This interval is very much larger than the interval of temperatures during which most of the remaining bodies exhibit an appreciable vapour tension. This tension, however, in the case of carbon does not, in Berthelot's opinion, correspond with a simple vaporisation, occurring without any intimate change in the chemical constitution of the body.

High-Potential Alternators.—At the recent National Electric Light Convention held at Boston, U.S.A., one of the papers read was by Mr. G. N. Eastman, the subject being "Grounding the Neutral on High Potential Alternators," of which a summary is given in the *American Electrician*. The author presented a mathematical demonstration to show that the advantages obtainable by insulating the [of neutral a high-tension alternating-current system from the earth, will be more than offset by the liability of developing abnormally high potentials relative to the earth. The paper was based on a consideration of the three-phase four-wire system of the Commonwealth Electric Company, of Chicago, and was illustrated by diagrams showing the voltages obtained with wholly-insulated and neutrally-grounded circuits. The author expressed the opinion that a proper method of grounding the neutral of generators is through as low a ground resistance as can possibly be obtained, thus fixing the maximum potential which can be obtained between a system and ground at the normal potential which will exist between the neutral of the generator and its phase terminals. The systems of the Chicago Edison Company and the Commonwealth Electric Company have been operated with a grounded neutral for a period of four years, during which time they have apparently been entirely free from the high-potential breakdowns that have occurred on other systems of a similar character entirely insulated from the ground.

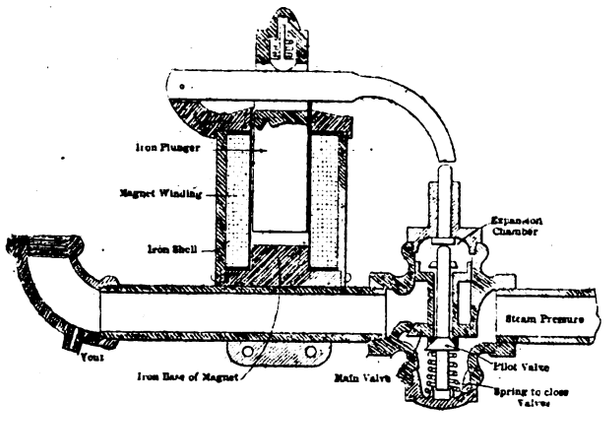
The Positive Auxiliary Car-Lighting System.—The Lackawanna and Wyoming Valley Railroad Company has recently adopted an auxiliary car-lighting equipment of the automatic type, supplied by the Kinsman Electric and Railway Supply Company, of New York, for the purpose of providing lighting current when the propulsion current is interrupted. The Kinsman system, described by the *Street Railway Journal* of New York, consists of an equipment for providing electric current for the car from a small storage battery, which will be operative normally only when the propulsion current supplied to the car is interrupted. The passage of the propulsion current through the regular lighting system of the car is arranged to normally pass a charging current to the storage batteries for the auxiliary system, and by means of an automatic switch to keep the auxiliary lighting system cut out. Whenever the propulsion current is interrupted, however, the automatic switch releases and throws the auxiliary lighting circuit on to the storage batteries, leaving them connected in and burning until the propulsion current again flows. The system is convenient and economical, as only a very small battery is required in each car. Upon the above-mentioned railroad each car is equipped with a storage battery of six cells of five ampere-

Digitized by Google

hours capacity each, the batteries being enclosed in a box for convenience, occupying very little room and weighing only 60lb. in all.

Hydro-Electric Development in Mexico.—A few weeks ago we referred to the awakening which has lately taken place in Mexico in regard to the utility of electricity. The country possesses great natural resources in this respect, water being found in great abundance near the larger centres of population. There are but very few large streams in the republic, but owing to the mountainous nature of the greater part of its area there is an abundance of small streams, which, owing to their rapid fall, offer a great amount of power. Certain obstacles, however, remarks the *Electrical World* of New York, have to be overcome in using this water power. One especial fault is that many of the streams have dry beds for about six months of the year. The problem to be solved in such cases is how to profitably utilise the power which can be derived from such streams during the rainy season, when they are full. In some cases where power from streams that are dry during part of the year is now being utilised to generate electric power for lighting, etc., coal or other fuel is used during the dry season. The exclusive use of coal or other fuel for generating steam to run the plants would render the cost of their operation prohibitive to profits, but by using the water power for some six months of the year profits can be made. Another obstacle is that of vegetable growths, such as water hyacinths, which greatly impede the use of water from streams infested with it. This obstacle has, however, been overcome to a very great extent in the United States, and there is no reason why it cannot be overcome in Mexico.

An Electrically-Operated Valve.—The accompanying diagram, reproduced from *Power*, shows a valve which is operated by the action of an electric current flowing through the solenoid mounted over the pipe shown. The action is to draw down the iron core and press down the curved lever, which opens the small pilot valve just under the main valve, admitting steam to the expansion chamber



above. The pressure on both sides of the main valve is by this means balanced, and a further motion of the lever opens the main valve, allowing steam to flow by it. A spring under the pilot valve seats it when the current is turned off the solenoid, and a spring mounted in the top of the solenoid plunger raises it above the bent lever when out of action. The device is manufactured by the Electrical Appliance Company, Cincinnati, Ohio, and recommended by them for use on a whistle valve.

Electricity in Siberia.—The Russian engineers in charge of the construction of the railroad around the southern part of Lake Baikal, have encountered great difficulties in the course of the undertaking. It has been found necessary in one part of the railroad, some 16 miles in extent, to build 13 tunnels, totalling 2½ miles in length, besides making numerous cuttings in the rocky soil. Appreciating the results obtained in Western Europe and America from the use of electrically-operated drills, the engineers decided on employing the same method. At the middle point of the section a central power station has been established, with high-tension cables extending on both sides along the track. The station contains a boiler-house and a generating set of 120 h.p. output. A three-phase generator produces alternating current under pressure of 2,200 volts. The high-tension cables carry the current to four sub-stations, each of which contains an alternating-current motor operating a dynamo. Some of the dynamos generate alternating current at 110 to 130 volts, while others produce direct current for driving pumps and ventilators, and also for illumination. The alternating current is distributed through the whole plant, where 25 to 30 electric drills are constantly in operation. From the direct-current machines current is supplied to eight arc lamps and 200 incandescent lamps. The direct current is also employed for driving six rotating pumps and six ventilators which are employed for air purification after each explosion in the tunnels. Notwithstanding the Arctic conditions, the installation was completed in less than three months.

An Indicating Fuse Alarm.—A short account is given in the *American Telephone Journal* of one of the latest telephonic inventions—the automatic indicating fuse alarm. The value of this adjunct to the fuse panel consists of its reliability. It will be seen from the accompanying

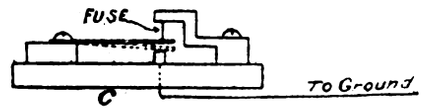


diagram that the fuse consists of a spring, which is held from a ground contact by means of a short piece of fuse wire. When, for any reason, this fuse blows, the spring makes contact with the ground and closes a circuit through a relay, which lights a lamp and also closes a second relay that causes a signal bell to ring. The relays, bell, and lamp should be placed as near as possible to the fuse panel. The fuse panel is divided off into sections, each section having a separate ground conductor connected in series with a relay, so that when any fuse for a section is opened, the relay of that particular section is closed, and the lamp is lighted and remains lighted until the fuse is replaced. A single-point switch is provided to open the bell circuit so as to prevent noise occurring while the defective fuse is being located and replaced. The number of circuits to each ground depends entirely upon circumstances, but it is preferable not to have too many, else the value of the fuse as a time-saving device is eliminated. Although the initial cost is higher than that of the ordinary fuse, the additional expense is repaid by the advantages afforded for the rapid location and removal of trouble.

The Civil Engineers' American Visit.—Provisional arrangements have been made for the tour of the Institution of Civil Engineers, who, like their brethren of the electrical profession, are to visit the States and Canada in September. The main party will leave Liverpool by the ss. "Etruria" on Sept. 3, and are expected to reach New York on Sept. 10. On the 13th of the month a formal reception of the visitors by the American Society of Civil Engineers will probably take place, the remainder of the week being spent in examining places of interest in the city and its environs. On the following Monday

Digitized by Google

the party will proceed to Montreal, and will be engaged until the 27th in visiting various places of interest in the Dominion under the guidance of the Canadian Society of Civil Engineers. Chicago will be visited on the 28th, and on the 30th the party will arrive at St. Louis, where the exhibition will claim their attention. The programme gives a list of hotels at the different cities, and whilst members of the visiting party will communicate directly with the proprietors of the hotels, the secretary of the institution will be glad if they will inform him of the accommodation they have ordered, as he may possibly be able to facilitate arrangements, and also the names of any members of their family by whom they propose to be accompanied. Members are reminded that the arrangements made with the Cunard Steamship Company enable members to book their passages by the ss. "Etruria," with the option of return by any of the Cunard steamers from New York or Boston, or by any of the Allan Line steamers from Montreal and Quebec, at a reduction of 25 per cent. on the ordinary first-class fares. Those members who propose to take part in the tour and have not already secured outward passages are advised to do so without delay.

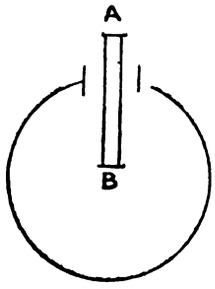
Mussoorie.—The Municipality have decided upon a hydro-electric plant for furnishing Mussoorie and Landour with an adequate water supply and for the provision of electrical energy for lighting and power purposes. Hitherto the only illumination in the streets has been that afforded by a few oil lamps. The *Indian and Eastern Engineer* gives some particulars of the scheme, which has been prepared by Mr. P. Billinghurst, late of the Bikanir State service, who found, as the result of comparisons between steam, oil, and electric power, that the last-named was distinctly the most economical and best adapted to the circumstances. The generating plant will be located at Kimpti Falls, 2½ miles from Mussoorie. The effective head of water is reckoned to be 776ft., after deducting the loss of head due to friction in the pipes, which is given as 45ft., the velocity of flow being taken at 5ft. per second. The quantity of water available is never less than 6½ cubic feet per second, and the power available at the generator terminals is calculated to be about 400 e.h.p. Allowing for 6 per cent. loss in the line at full load, there will be some 280 kw. available for distribution. For the water supply, springs between Kimpti Falls and Mussoorie will be utilised. The scheme provides for the lighting of 13½ miles of roads, and for the supply of electricity sufficient for the lighting of all buildings in Mussoorie and Landour. The surplus power remaining after providing for the above and pumping purposes, the latter being conducted during the hours when lights are not needed, will be available for private lighting and heating. The generator house will be fitted with four 85-kw. turbine-generator sets and two turbine-exciter sets. The load being a fluctuating one, a dam will be built after the present power is taken up, and this will increase the power for the evening load to about 800 h.p. The turbines will be of the Pelton wheel type, fitted with electric governors and designed for a speed of 600 revolutions per minute, with a direct drive to the generators. These will be of the alternating-current three-phase 60-cycle revolving-field type, giving 5,500 volts at 600 revolutions per minute. The power will be transmitted to 12 transformers situated about every 3,000ft. through the stations. The transformers vary in size from 5 kw. to 70 kw. The high-tension mains are of sufficient size for double the expected load. Energy will be distributed from the transformer houses at a pressure of 230 volts and delivered to consumers at 225 volts. The mains for the motors at the main pumping station feed two 120-kw. transformers arranged in parallel. These feed through the usual switchboard instruments two motors of 150 h.p. each. The motors are of the induction type, with starting resistances and short-circuiting switches, running at 450 revolutions per minute. The distance from the generator house is about 10,000ft., and the voltage is 220, with a frequency of 60 cycles. The scheme is estimated to cost some £47,000, and the annual expenses, including capital charges and depreciation, are put at £4,300. The present cost of lighting and water supply is given as £1,820. It is proposed to supply energy at 4d. per unit for light and 3d. for power and heating; and it is calculated, at a conservative estimate, that the sale of electricity in the first year for private lighting alone will amount to some 48,000 units. The scheme should prove a great boon to the inhabitants, and appears to justify the prediction of Mr. Billinghurst that it will show a considerable profit, at any rate after the first few years.

A Novel Gas-Engine.—A novel gas-engine is being brought out by the Maschinenbaugesellschaft München, in conjunction with the Austrian firm of Bromovsky, Schuls, and Sohr, Prague. This four-time motor, designed by Mr. Güldner, embodies a high improvement as regards the thermal utilisation and specific efficiency. The arrangement of the crank and governor shafts is extremely solid and practical, and as, moreover, the working cylinder is purely cylindrical and free from any projection, the thermic expansion will be quite uniform. Any parts in and near the cylinder cover are readily accessible. The valves and igniters may be removed and replaced in position (in case of a revision being necessary) with a few manipulations, and without removing any parts of the governor or any conducts, in addition to which the inner walls of the cylinder may be cleaned thoroughly without the cylinder cover being withdrawn, which is highly important from the point of view of safety in working. The gas valve, being governed like the inlet and outlet valves, is not liable to become obstructed by impurities. The valve cones are very strong, and guided in special slides, and the governing levers are applied between the inner and outer slides, so as to exclude any possibility of the cones being thrown to the side, and to maintain continually a perfect tightening. In order to eliminate any heat effect in the valve springs, these are located at the upper end of the cone shafts. The magneto-electric ignition is so arranged as to allow of the moment of ignition being readily adjusted by hand during operation. The igniting current is supplied from a Bosch apparatus arranged above the governing shaft and moved from the latter so as to allow of the regulation alluded to. The regulation of speed is effected by throttling the cylinder contents, the composition of the charge being influenced simultaneously with the quantity so as to maintain with any load a safely igniting mixture. The design of the combustion chamber as a regular cylinder with smooth walls greatly facilitates a thorough expulsion of the exhaust gases, while avoiding a dispersion of the fresh mixture, which is so prejudicial to a complete ignition. On the other hand, a complete combustion is secured by the efficient position of the igniter in the axis of the cylinder, which, according to thermo-dynamics, is the most suitable place possible. The inflammation is started in the centre of the condensed charge, whence it may diffuse to all sides on the shortest possible paths through the whole charge of the cylinder. To these constructive details seems to be due the extraordinarily high utilisation of heat, as borne out by tests recently made. From experiments by Prof. Schröter, made on the first Güldner motor built in Munich, it is inferred that as much

Digitized by Google

as 42·7 per cent. of the amount of heat actually supplied to the engine with the lighting gas is transformed into indicated work, while with any other lighting gas motors the figure of 30 per cent. is seldom even slightly exceeded. The same applies to suction gas operation, where a figure of nearly 29 per cent. is recorded, including any losses in producer and purifier. The extraordinary elasticity of the output of the motor, which may be increased within wide limits, should be especially mentioned. In fact, while in older types of suction gas motors, the mean piston pressure is seldom upwards of, say, 30lb. to 35lb. per square inch, the figures observed with Güldner motors—viz., more than 45lb. per square inch—are approached only in the Diesel petrol motor. In modern types of steam-engines, the average steam pressure at normal load is about one-quarter.

Electric Arcs of Large Surface.—Prof. K. Birkeland has, according to the *Elektroteknisk Tidsskrift*, Christiania (No. 16, 1904), taken out patents for a process for obtaining electric arcs of a very large surface. The invention is based on the production of a chemical compound or a decomposition of gas mixture or gases by means of a special kind of electric arc. As is well known, electric arcs will exert chemical effects on gases, this effect being essentially dependent on the magnitude of the contact surface between the arc and gas mass With a view to augmenting this contact surface, the use had been suggested of electrodes of such an arrangement and performing a movement with respect to one another such as to expand the arc in its longitudinal direction until it is closed on the mutual distance of the electrode becoming too great.



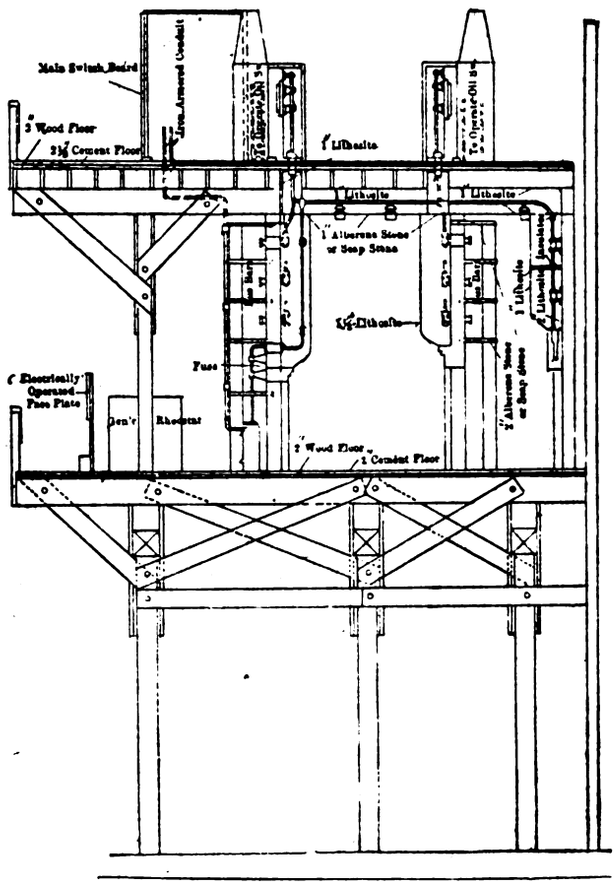
With these processes, exceedingly small currents had, however, to be used. The process suggested by Birkeland consists in having the point of contact between two conductors, one (or both) of which is susceptible of a vibrating movement, traversed by an electric current in a strong magnetic field. The inventor has found under these circumstances an electric arc formed between the contact points, even in the case of the distance between the latter being increased only to a fraction of a millimetre, to be thrown violently upwards or downwards, so as to form a large and plane permanent arc disc, susceptible of absorbing high amounts of energy and current. This process seems to be especially adapted to producing nitrogen-oxygen compounds of air, and in the description given below it is assumed that the method is to be applied to the oxidation of nitrogen. After arranging a circular electromagnet, as shown in the accompanying diagram, the air is conveyed through a prismatical tube, A B, being insulated fireproof in its interior. This tube is, by means of partition walls parallel to the magnet surfaces, divided into shallow compartments or channels. In each of these compartments there is placed a special interrupter, working both for alternating and direct currents, and consisting in its simplest form of two metal rods, one end of which is clamped fast, while the other terminal is maintained in good contact with the springs. One end is prevented by means of a stop from swinging upwards, while the free end of the other rod is prevented in a similar way from downward swinging. Now, in the case of a high-tension alternate current, or a low-tension direct current of convenient intensity, traversing all the interrupters in parallel (convenient inductive resistances being connected to each of them), there will result an alternate movement of the two rods, one swinging down and the other swinging up alternately, so as to form frequently a very slight interruption of the contact, when the remarkable phenomenon above alluded to will occur, and a violent projection of the arc be observed, resulting in the space becoming filled with expanded arcs. In the case of fairly high tensions being available, the current may be thrown partly or wholly through the interrupters in series. In the case of direct current being used, only one spring of the contact interrupters will be set vibrating. The air may be made to traverse either all the channels in parallel or partly in series, or else wholly in series so as to cause it to pass subsequently before each of the arcs, a contact thus being produced with an exceedingly high number of arc discs. In order to further augment the number of arc discs the air comes in contact with, several systems of the same kind may be connected to one another. Instead of the automatic interrupter above described, some other means are available for producing the frequent slight interruptions. Big tuning forks driven by small electromagnets may, for instance, be used for the purpose.

The American Visit.—A detailed programme of events in connection with the reception and entertainment of its visitors by the American Institute of Electrical Engineers and the holding of the International Electrical Congress at St. Louis, just received from Mr. R. W. Pope, the secretary of the American Institute, shows that practically all the arrangements have now been completed. An outline of this programme was given in our issue of April 22, and we cannot do better than reproduce our notice, supplemented by the additional features appearing in the later programme: "The itinerary will commence on Sept. 4 with a journey up the Hudson River by steamer. In the course of the week the visitors will be entertained by the New York corporations, under whose guidance they will inspect the power-houses of some of the chief New York companies; there will be a formal reception under the auspices of the institute; the party will be received and entertained at Schenectady by the General Electric Company, following which they will leave for Albany, and in the evening start on an all-night trip to Montreal; McGill University and large transmission plants in the neighbourhood will be visited; the Niagara Falls will receive attention on the Friday; and the next day will see the party exploring Chicago, leaving in the evening for St. Louis. On Monday, Sept. 12, the opening of the international electrical congress, at 10 a.m., will take place, and on the Wednesday there will be a special joint session between the American and British institutions. Sessions of the various sections of the congress will be held from the 13th to the 17th, after which the party will leave St. Louis for Pittsburg. The following week, commencing Sept. 19, will begin with a reception and entertainment by the Westinghouse Company, other events being the inauguration of the National Bureau of Standards at Washington, and visits to Philadelphia and Harvard University, the Massachusetts Institute of Technology, and other places of interest at Boston." The last-named events—the visits to Harvard, the Massachusetts Institute, and other places at Boston—appear to have been transferred to the other end of the programme, and will initiate the tour on Sept. 3. For the convenience of visitors arriving at New York on or prior to Sept. 1, and who will proceed to Boston to join the main party, an excursion has been arranged *viâ*

Digitized by Google

Newport, leaving New York by steamer on the evening of Thursday, Sept. 1, at 5.30 p.m. After spending a day at Newport, those who go on this excursion will proceed to Boston, arriving there at 7.13 p.m. of the same day in time to join the main party in seeing Boston on Saturday, Sept. 3. Inclusive terms of £4 have been arranged for this trip from New York to Boston, *viâ* Newport and direct return, including hotel expenses in Boston. The circular tour will be by special train composed of Pullman drawing-room and sleeping cars, and will leave the Grand Central Station of the New York Central and Hudson River Railroad at 8.45 a.m. on Tuesday, Sept. 6. This train will run along the east bank of the Hudson River as far as Albany, giving views of the Palisades and of the Highlands of the Hudson. All visitors are invited to take part in the circular tour. The visitors will be accompanied during the circular tour by representatives of the American Institute of Electrical Engineers, many of whom will be accompanied by ladies, to act as guides to the visitors. Members desiring to participate in the circular tour may obtain tickets in advance through the secretary of the British Institution, to whom intimation should be sent without delay, so that there may be no lack of time for communicating with the American authorities. It may be mentioned that the fee for membership in the St. Louis Congress is £1. 0s. 10d., entitling the subscriber to a copy of the *Proceedings* of the congress, which are to be subsequently published. The fee may be forwarded either to the secretary, Dr. A. E. Kennelly, Harvard University, Cambridge, Mass., or to the treasurer, Mr. W. D. Weaver, 114, Liberty-street, New York City. Between Sept. 12 and 17 the office of the secretary and of the treasurer will be at the Coliseum, St. Louis, Mo.; before and after that date they will be at the addresses given above. Other information is given in the programme relating to fares and hotels, the substance of which we have given in previous issues. The completeness of the programme testifies to the care exercised in its organisation.

The Large Switchboard at the St. Louis Exhibition.—The great switchboard at the St. Louis Exhibition is designed for the control of all the 6,600-volt three-phase current used on the exhibition grounds. It is a brick masonry structure, occupying two galleries and supported upon timber work. A description of it appears in the *Electrical World* of New York, and the diagram which we reproduce shows a cross-section. The switchboard consists mainly of feeder panels, as most of the generator panels will be located near the machines they control. The four generators in the service plant have control panels on this switchboard. There are in all 17 feeder panels, four generator panels, three total load panels, three exciter panels, two incoming feeder panels from the Union Light and Power Company, and one rheostat panel for controlling the water rheostats, spoken of as being inserted in the Union Light and Power Company's feeders at the entrance to the grounds for the purpose of bringing the decorative lighting up to full voltage gradually. On the control board proper, which is on the second floor of the gallery, and which has nothing but low-tension pilot circuits upon it, there are two sets of three-phase 'bus bars. Each feeder can be connected with either of the 'bus bars through the medium of a Westinghouse solenoid-operated oil switch. On each side of the oil switch there is a hook knife switch, so that the oil switch could, if necessary, be entirely disconnected, both from the 'bus bars and from its feeders, in case it should be necessary to make repairs on the switch. These switches can be operated either by a low-tension hand switch on the controlling board or by an automatic overload relay. From the accompanying diagram, it will be seen that the two sets of 'bus bars are located in independent brick compartments about 9ft. apart, one row of compartments occupying the rear part of the lower gallery and the other row the front part. On the second gallery is located the control switchboard and the high-tension oil switches. The hook knife switches, which are placed in the circuit on both the incoming and outgoing leads from the oil switches, are located on a concrete partition just back of the oil switches. Following the right-hand leg of the feeder as it leaves the three-conductor lead-covered cable at the bottom of the board, it passes up through two series potential transformers, which are used in connection with the switchboard instruments, and then up to the right-hand hook switch. From this switch it goes through the concrete partition to the oil switch, through one leg of the oil switch and back to the hook switch adjacent to the one through which it entered; then down from the hook switch to the 'bus bars. All holes where wires pass through floors have



Thomas porcelain bushings set in slate blocks with sulphur. The solenoid-operated oil switches are provided with concrete dividing walls, which separate the three legs of the circuit. On these switches the solenoid, when energised, draws the switch shut against the tension of a powerful spring. This spring is held closed by a trigger, and this trigger is released by a small magnet when the switch is to be opened. Each 'bus bar consists of two flat copper strips. The 'bus bars are separated from each other by soapstone slabs. The insulators upon which the 'bus bars are mounted are set in soapstone plugs in the wall. All the low-tension control circuits to the switchboard proper are run in iron-armoured conduit. Lithosite has been made use of freely to protect the bare connections on the wall back of the 'bus bars, and where the high-tension cables run under the floor between the first and second galleries. Arches are constructed in the brickwork just above the first gallery for the purpose of reducing the weight of masonry on the wooden supporting structure.

AN UP-TO-DATE DOCK INSTALLATION.

The London, Brighton, and South Coast Railway Company have shown commendable enterprise in equipping their Deptford wharf with electric plant for power and lighting purposes. At this point the company possess a fine frontage on the Thames, two open docks, and a barge dock wholly under cover. The latter has the principal interest for us, due to its splendid electrical equipment. It is 300ft. long and 70ft. wide, being served lengthwise and transversely by nine overhead electric cranes and hoists, capable of raising or lowering loads up to one ton with that remarkable expedition obtainable only with electrical control. The electrical equipment of the wharf is self-contained—that is to say, the necessary generating plant is installed on the spot. It was supplied by Messrs. Dick, Kerr, and Co., Limited, under the supervision of the railway company's consulting electrical engineer, Mr. Philip Dawson. Following is a brief description :

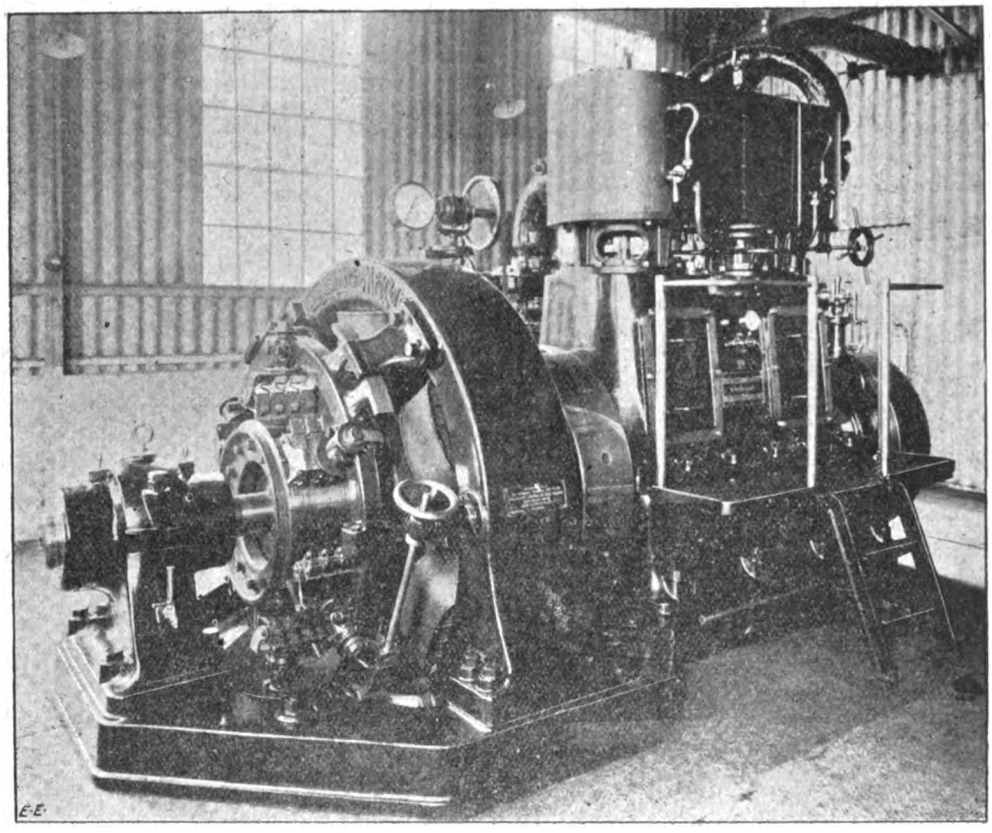
Boilers.—The boilers, which are of the horizontal water-tube type, were built by Messrs. Babcock and Wilcox. Each boiler is capable of evaporating 5,000lb. of water per hour under normal conditions, and approximately 6,500lb. per hour continuously when required, without undue forcing, the working pressure being 160lb. per square inch. The heating surface is of 1,790 square feet. Each boiler has a superheater fitted underneath the steam water drum. The superheaters will give 100deg. of superheat with ordinary stoking. Each superheater has approximately 198 square feet heating surface.

Mechanical Stokers.—Each boiler is fitted with a suitable mechanical stoker, and is so arranged that the rate of combustion may be varied over wide limits. Each stoker is capable of burning efficiently 1,000lb. of coal per hour without excessive wear or tear. The stokers are of the chain-grate type. The motive power is supplied by a horizontal shaft arranged in a culvert on the firing level at the front of the boilers. The stokers are driven by a motor connected direct to the horizontal shaft. The motor is of the Dick-Kerr standard, fully-enclosed, shunt-wound type, with a speed of about 600 revolutions per minute, and is worked at a potential of 220 volts.

Steam Feed Pumps.—One of Weir's patent direct-acting steam-driven feed pumps is supplied, delivering 1,400 gallons of water per hour at the normal rate of working, and capable of delivering at the rate of 1,700 gallons per hour continuously when required without undue wear and tear, against a boiler pressure of 160lb.

Electrical Feed Pumps.—In addition to the steam feed pump described above, an electrically-driven feed pump is also supplied. This pump is of the vertical three-throw type with variable stroke gear, the motor being connected to the crankshaft by worm gear. The pump shaft is run at a speed of 160 revolutions per minute, and the variable stroke gear is so arranged that the stroke of all plungers may be reduced to zero if required. The variations are made while the pump is running, and an indicator is fixed so that the relative discharge of the plungers may be shown in gallons per hour. The full range is from 0 to 1,600 gallons per hour. The pump is driven by a 5-b.h.p., 220-volt, 500 r.p.m. Dick-Kerr motor.

Engines.—The engines are of Messrs. Browett-Lindley's vertical high-speed enclosed self-lubricating, two-crank, compound type, capable of developing 200 i.h.p. at 155lb. pressure as normal load and 300 i.h.p. as overload, and are non-condensing.



Direct-Coupled Engine and Generator at Deptford Wharf Power House.

Generators.—There are two direct-current generators coupled direct to the engines, the output of each generator being 125 kw. with a speed of 380 revolutions per minute, and they are designed to carry an overload of 50 per cent. for one hour, the current being developed at a voltage of 230-260. They are built to work either as shunt or compound machines, and are in every respect in accordance with the standard practice of Dick, Kerr, and Co., Limited.

Switchboard.—The switchboard, which was built by Dick, Kerr, and Co., is fixed to an elevated gallery, and consists of eight polished slate panels, each supported independently on iron frames. Each panel of the switchboard is supplied in three sections. The board consists of two generator panels, two distributing panels for the power circuits, one distributing panel for the arc lamp circuit, one accumulator and booster panel, one panel for recording instruments, and one distributing panel for incandescent lamp circuits.

Storage Battery and Booster.—The storage battery consists of 112 cells, which when fully charged are able to give a discharge current of 300 amperes for one hour with a final E.M.F. of 210 volts, and momentary discharges of 750

Digitized by Google

amperes without injury. The battery was made by the Chloride Electrical Storage Company. The Highfield reversible booster supplied with the battery is capable of giving a continuous output of 300 amperes when at its highest potential, and is able to stand 50 per cent. overload for two hours continuously, and 100 per cent. overload for short periods without heating or sparking.

Overhead Travelling Crane.—The six-ton, hand-power, overhead travelling crane was built by Jessop and Appleby, Leicester, and has a span of 27ft. 10in. All motions are worked from below.

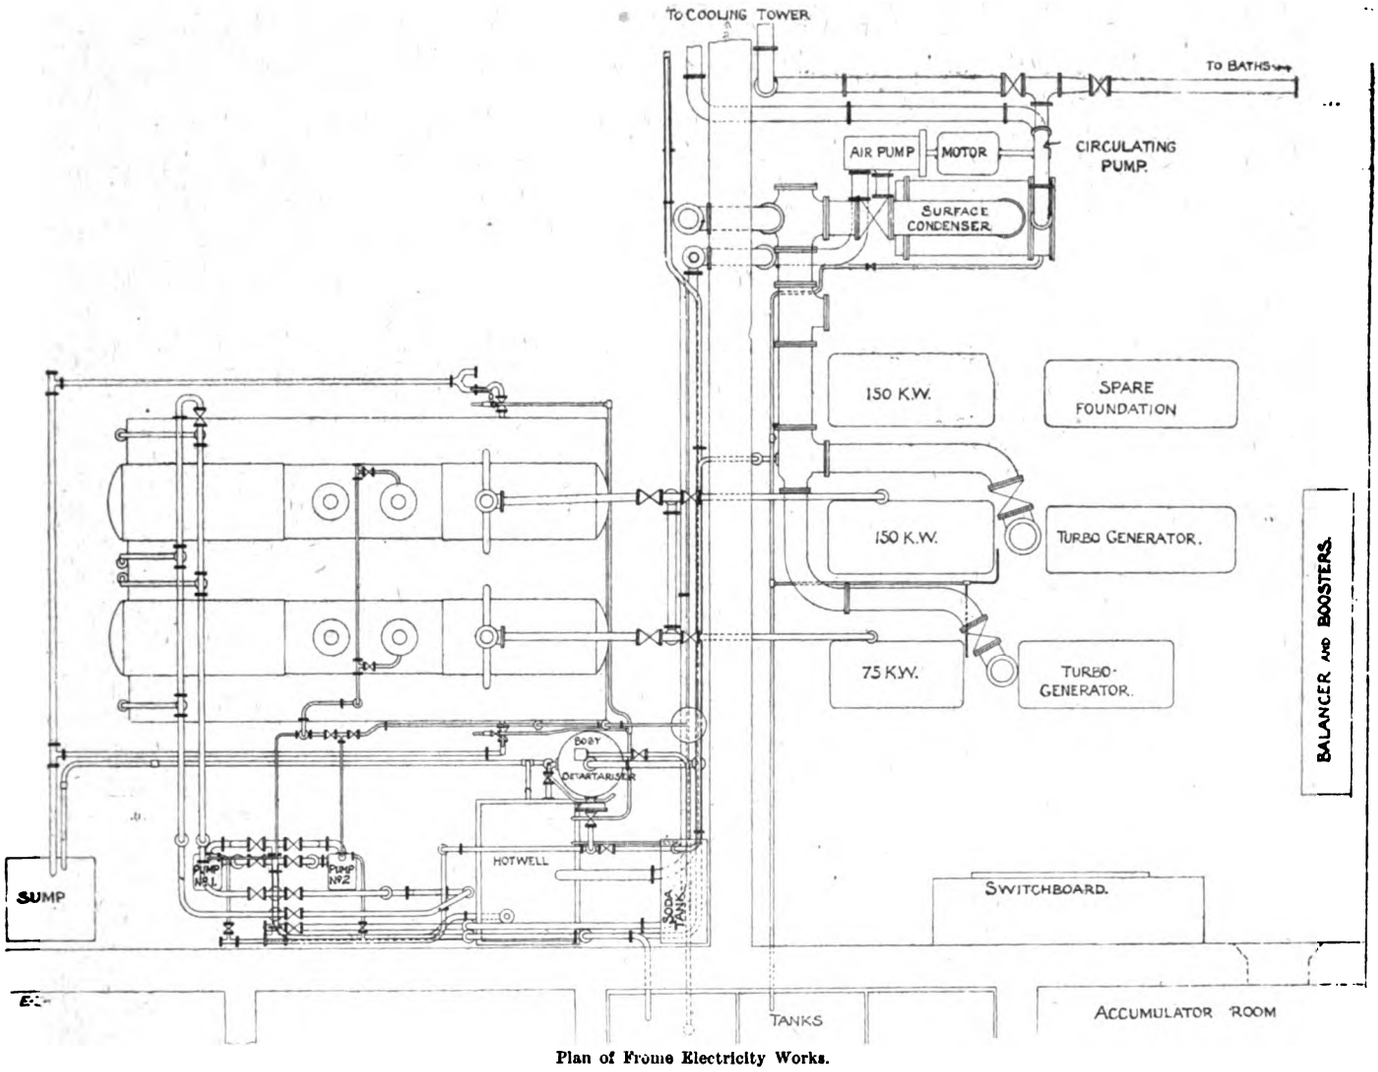
FROME ELECTRICITY SUPPLY.

BY B. PONTIFEX.

This system is of interest from the fact that small units driven by steam-turbines have been adopted, and also that the entire urban district is to be lighted by electricity to the dissatisfaction of the gas company. The provisional order was obtained in 1901 by the Urban District Council, Messrs. Medhurst and Lloyd having been appointed consulting engineers. On April 6, 1903, a contract was entered into with Messrs. Edmundson's Electricity Corporation, Limited, on condition that the Council found the capital and Edmundsons paid interest and sinking fund on same, amounting to 6 per cent. per annum; Messrs. Edmundsons to erect the station and run it for 25 years, provided that the Council do not wish to take it over before that date. If, however, they decide to do so at the end of seven years they must pay 15 per cent. on the capital outlay, at 10 years 10 per cent., and at 14 no premium.

The original amount of the contract was £20,156, but this has since been increased by £8,500 to include the cost of street-lighting and private supply in all streets where there are lamps. Current is supplied at 7d. and 3d. for lighting on the maximum demand system, or a flat rate of 6d. Power and heating are charged 4d. and 1d., or a flat rate of 2½d. per unit. Messrs. Edmundson are undertaking contract work for wiring private houses, shops, etc., on the hire-purchase system for 3, 5, 7, 10, or 14 years, charging 5 per cent. on outstanding amounts; also "free wiring" at a rate of 1s. 6d. per annum per lamp installed.

The buildings are substantially constructed of local stone, with a temporary wall of corrugated iron at the west end to allow for extensions. There are two Babcock and Wilcox boilers, each with 1,600 square feet heating surface, working at 160lb. per square inch. Superheaters are fixed direct on each boiler giving 150deg. F. superheat to the steam. The boilers are fitted with Meldrum's "Koker" stokers driven by a 2-h.p. motor. The boilers are lagged with mica boiler covering. An economiser has not yet been fixed, but space has been left for it between the boiler-house and stack. The latter will be of stone and brick, 110ft. high from ground-level and 6ft. in diameter. The feed pumps are by Messrs. J. P. Hall and Son, Limited, of Peterborough, and are each capable of delivering 200 gallons of boiling water per hour against a boiler pressure of 160lb. per square inch, with a piston speed not exceeding 40ft. per minute. The suction pipes are arranged to take water either from the hot-well, from the cooling tanks, or from the feed storage tanks. All steam-pipes are of lap-welded steel with mild-steel flanges screwed and brazed on. The exhaust pipes are of cast iron.



Plan of Frome Electricity Works.

The turbines are of Messrs. Parsons's make, direct coupled to bipolar generators. The governors are to regulate speed from full load to no load within 2 per cent. The following tests were made at the manufacturers' works:

Generator.	R.P.M.	Load.	Vacuum.	Lbs. coal per kw.-hour.
75 kw.	4,000	Full.	24in.	27·6
		Half.	24in.	38·7
150 kw.	3,500	Full.	25in.	24·3
		Half.	25in.	31·0

Digitized by Google

The generators are capable of carrying a 10 per cent. overload for two hours, the smaller one has a grooved commutator, and there is an insulated steel band shrunk on the centre of the commutator of the larger machine. Wire brushes are used, and are held on to the commutator surface by counterbalance weights.

The condensing plant consists of a surface condenser, by Messrs. Cole, Marchant, and Morley, with 700 square feet of cooling surface, capable of giving a vacuum of 26in. when dealing with 6,000lb. of steam per hour, the temperature of the circulating water being not less than 80deg. F. The condensing water is to be taken from the public baths twice a week to the tanks under the cooling tower, which is being supplied by the Klein Engineering Company. Any make-up water drawn from the feed tanks will be passed through a Boby heater-detartariser, where it will be heated by the exhaust from the feed pumps, and the hardness reduced from 25deg. to 2deg. The balancers and boosters have their armatures all connected together on one shaft. The balancers are capable of dealing with an out of balance of 60 amperes running at 1,300 revolutions per minute; the boosters each give 54 amperes at 85 volts.

The switchboard is Edmundson's standard type, with Kelvin and White's instruments. There are two generator panels, three battery panels, middle-wire panel, balancer panel, and four feeder panels. Copper rod is used for the connections behind the board. The battery is composed of 260 cells of the D.P. Company's new standard type, of 400 ampere-hour capacity when discharged in 10 hours.

The mains were laid by Messrs. Edmundson, and are as follows: Feeders are Callender's triple-concentric, lead-sheathed, steel-taped, laid direct in the ground. Distributors in the compulsory area (about two miles) are the same firm's three-core pattern, sheathed and armoured as above, and in the outside area an additional 11½ miles has been laid with four-core cables, the fourth core being used for street-lighting.

Supply is three-wire continuous-current, 480 volts between the outers Street-lighting is to commence on Aug. 1 next. The contract covers 260 half-ampereNernst lamps (80 c.p.), of which 46 will be burnt all night and the remainder from dusk to 11.30 p.m. There are 10 Reason twin-carbon arc lamps with two 25-c.p. incandescent lamps on the same pillar, which will be switched on at 11.30 in their place. Current to the Council is supplied for all purposes at 2½d. per unit.

The above work has all been carried out for Messrs. Edmundsons under the personal supervision of Mr. H. M. Nicholl, to whose courtesy I am indebted for the foregoing particulars.

DESCRIPTIVE ACCOUNT OF THE NEWCASTLE CORPORATION TRAMWAYS SYSTEM.*

BY A. E. LE ROSSIGNOL, M.I.C.E., M.I.E.E., GENERAL MANAGER AND ENGINEER, NEWCASTLE CORPORATION TRAMWAYS.

In the following paper the author has endeavoured to give some account of the principal features of the Newcastle Corporation tramways system, which he thinks might interest the members of the Municipal and County Engineers.

The configuration of any tramway system is largely determined by the situation of the town and the character of its existing traffic; and the situation of Newcastle is peculiar, inasmuch as the greater part of the town is situated on a hill forming the north side of the valley of the Tyne. This valley being narrow at the east end of the town and wide at the west end, it follows that the tramway lines have not been able to approach the river closely at the east end of the town, but run along the top of the hill forming the valley; whilst at the west end of the town, where the valley is much wider, one line parallels the river almost at the same level. The existence of this wider valley, at the west end of the town, too, has brought into existence large works along the river bank, the principal one being that of Messrs. Armstrong, Whitworth, and Co.; and the workers in those factories are unable to find accommodation in that part of the town alone, but are obliged to live at the eastern and northern parts of the city, and the heavy tramway communication between east and west has become a necessity.

The population of Newcastle is rendered dense in certain parts, owing to the existence of a large space of open ground in the north—the Town Moor—which has compressed the town into a sort of butterfly shape, the central portion between the two wings being occupied entirely with shops and business premises. The consequence of this configuration of Newcastle is, that all the main lines of tramway communication between east and west and the north and centre (where the only railway station of any importance is situated) have to pass through the restricted central portion, which gets very congested at certain times.

View from the West of Power Station and Offices complete. Newcastle Tramways.

The history of the tramways in Newcastle commenced in 1878. After the Corporation had constructed about eight route miles of track, they leased the working of it to a company for 21 years, horses being the motive power. On the expiry of that lease the Corporation set about the reconstruction of the whole of the lines, which were then in a very bad state, and the introduction of electric traction; and, in the planning out of the system, a site which was owned by the Corporation approximately near the centre was chosen for the position of the power station, so as to enable direct current at 500 volts to be the system of supply. The site had several disadvantages to counterbalance the advantage of being near the centre, inasmuch as it was some distance, over a quarter of a mile, from the river, and 90ft. above the water-level; and, further, it was all filled-in ground, being on the site of an old dene or deep valley, which had been filled up level some time before. This situation rendered a special system of foundations necessary. The whole of the site for each building was excavated to a distance of 8ft. below the basement level, all hard ground at either end being taken out, and a block of concrete formed the full distance and width of each building, 8ft. thick, interlaced with steel girder rails, all bolted and fishplated together, and thus each building practically floats on the soft ground below it. The foundations of the chimney, however, situated at one side of the old valley as it was, were differently arranged, piles being driven down into the hard ground below, and a heavy

* Paper read before a district meeting of the Incorporated Association of Municipal and County Engineers at Newcastle.

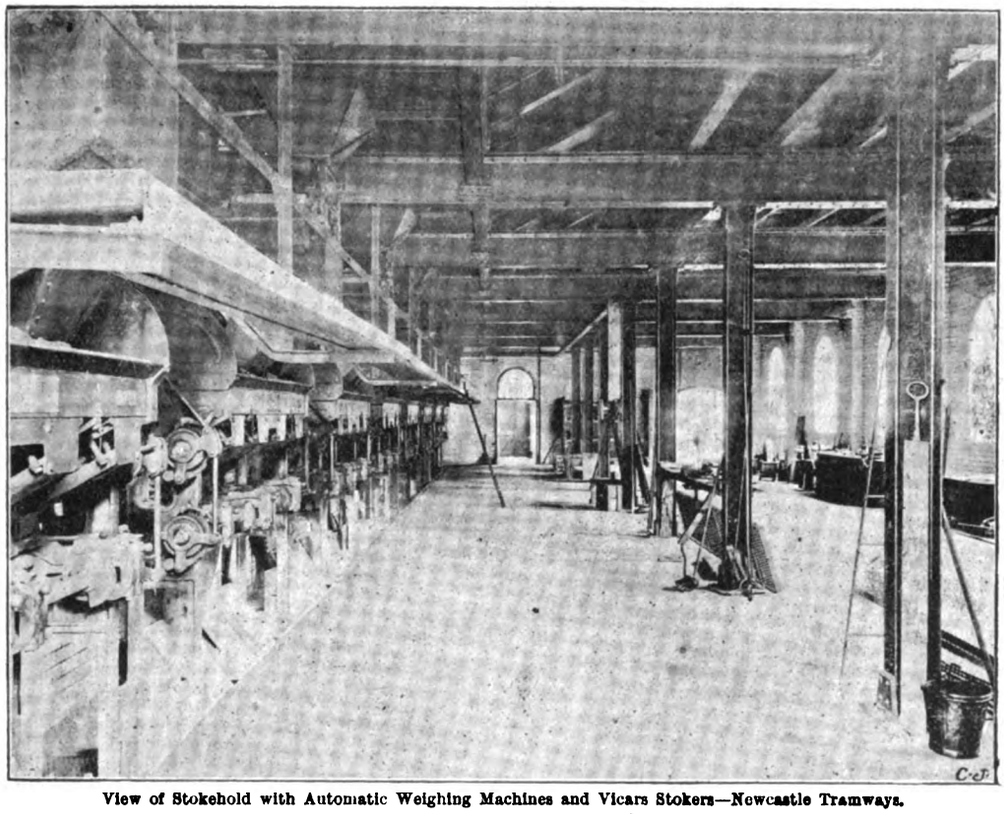
Digitized by Google

block of concrete, 30ft. square, formed on top of the piles. On this an octagonal brick chimney, 180ft. high from the level of the concrete, was built up, with a clear internal diameter of 9ft. The whole of the power station buildings

View from the West of Power Station under Construction, showing Steel Framework—Newcastle Tramways.

are steel-framed, filled in afterwards with brick walls, with steel roof principals carrying wood roofs. Coal comes direct from the railway into the top of the boiler house, being tipped direct into the bunkers; from there falling by

All the four big engines are of the vertical marine type, with Corliss valves; two being compound, of 1,000 h.p. each; one triple-expansion, of 2,000 h.p.; and one triple-expansion, of 3,000 h.p., made to the author's specification, is now being installed. These engines are all direct-coupled to the dynamos and generate current at 550 volts, which is distributed to the various feeders through a large switchboard. This, contrary to the general practice of



View of Stokehold with Automatic Weighing Machines and Vicars Stokers—Newcastle Tramways.

gravity through automatic weighing machines into the hoppers of automatic stokers.

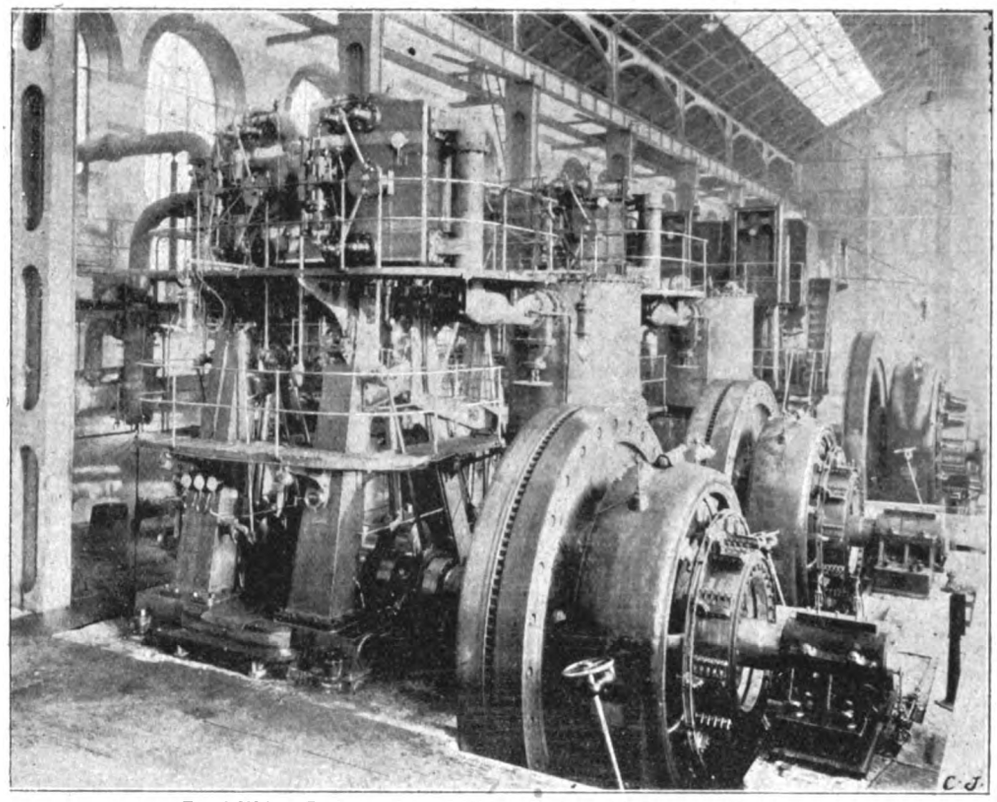
There are 12 large size Lancashire boilers installed, which supply steam to four slow-speed engines for traction purposes, and one high-speed engine for electric lighting.

putting the switchboard on a gallery, is mounted on the engine-room floor on a glass floor so as to avoid possibility of shock. In the basement below the cables pass along a subway to the ends of the various lines of conduits.

In one respect the station is peculiar, in that the whole

Digitized by Google

of the circulating water for the surface condensers of the engines has to be pumped up a quarter of a mile and 90ft. high from the river. As this would involve a big loss in the ordinary way, the water after passing through the surface condensers is carried back in another pipe to the pumping station, where the centrifugal pumps are situated, driven by electric motors, and passes through turbines on the same shaft as the motors, thus helping to drive the pumps, and returning about 50 per cent. of the power to the motor. By this means the cost of power for pumping purposes is reduced by about half from what it would otherwise be. A special high-lift centrifugal pump is used, the largest set being capable of delivering 3,000 gallons per minute to a height of 100ft.



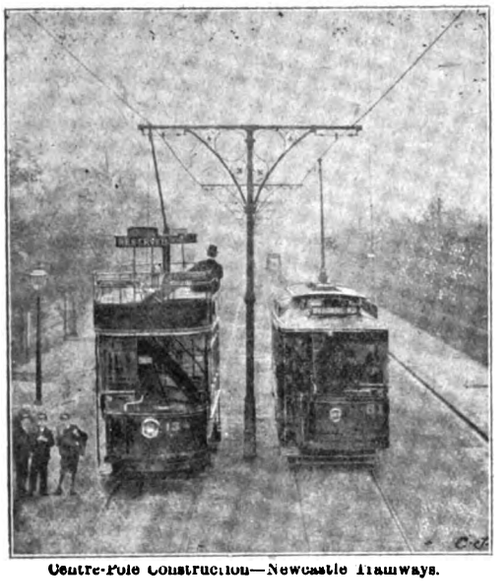
Two 1,000-h.p. Engines and one 2,000-h.p. Engine, with Dynamos—Newcastle.

The construction of the track in Newcastle was at the time it was commenced fairly typical of all track construction being carried out at that time. The gauge is the standard 4ft. 8½in., and the rails were laid on a concrete foundation, 7in. thick, extending over the whole track. The rails weigh 101lb. to the yard, and the double tracks were laid 3ft. 6in. apart in the narrow streets and 5ft. 8in. apart where centre poles were intended to be used.

View of Monument Junction under Construction—Newcastle Tramways.

Digitized by Google

Between the centres of the track the conduits, consisting of special fireclay ducts, were laid solid in concrete; and as the Corporation wished to avoid continually pulling up the streets as extensions were required, a larger number of ducts than were actually necessary at the time were laid in nearly all the streets. A great many difficulties were encountered in laying the ducts, owing to the presence of large masses of pipes under the surface of the streets, but care was taken that the ducts always drained towards a manhole so as to avoid the formation of a pocket in which water would lie. From the power station three main lines of ducts were laid, one of 30 ducts to the west, one of 30 to the north, and one of 12 to the east; and the manholes vary in size from 8ft. square for the large numbers of ducts to 4ft. square for any number of ducts up to nine. All manhole covers are provided with drip-pans, and ventilated so as to avoid accumulation of gas, and trap-drain connections are run into all manholes which are not below the level of the adjacent sewers. All sharp curves on the track are laid with increasing curvature, commencing with a long radius, and finishing with the required radius at the centre of the curve, and all have been laid to standard gauge, whilst the whole of the special work, points, and crossings has renewable hard-steel centres, which are fixed in with white metal, and can be taken out when worn and new ones put down.



Centre-Pole Construction—Newcastle Tramways.

Two systems of paving are in operation—namely, granite blocks and hardwood paving, the latter having been adopted for the whole of the central portion of the city. Experience has shown since the track was constructed that the heavy bogie cars, which are run on some of the routes, cause a great deal of loosening of the paving, which originates from the hog-backing of the rails, due to the rolling out of the top fibres of the metal; and this hog-backing of the rail leaves a cavity underneath the base into which water find its way, and acts as a hydraulic pump, each time a car passes over, to raise the adjacent paving. This shows up very much on the roads on which the heavy bogie cars run, and can only be cured by the insertion of anchors into the concrete below the rail, which hold the rail firmly down to the concrete and prevent this action, and all the new work is being carried out with the anchors. The first rails used were 45ft. in length, but the length has now been increased to 60ft., and all joints are laid butted up together, a clip fishplate being used, which holds the bottom flanges in line and prevents jumping at the joints.

The overhead work is of heavy construction, 0·4in. diameter trolley wire being used, suspended over the centre of each track by centre-pole brackets where the streets are wide enough, or by span wires and side poles where the streets are narrow, and automatic lever frogs control the trolley at junctions. Combined with the overhead work is the electric lighting by arc lamps, of the whole centre portion of the town, 200 lamps being fixed at the top of the poles in the main streets. These lamps are supplied with current by separate cables from the power station, are 40 yards apart, and are on alternate cables, so that should one series fail the street will still be supplied with half the usual amount of light, and in summer an economy can be effected by half of the lamps never being lit, whilst half are always turned out every night after 12 o'clock. The overhead work itself is divided up into the usual half-mile sections, which are fed by separate feeders in such a way that the breakdown of any outlying section does not affect the centre portion of the city.

There are several types of cars in use; single-deck cars having to be adopted at first because of the existence of several bridges, which prevented double-deck cars being used. The height under these bridges has now been increased to admit double-deck cars by lowering the road, but the single-deck bogie cars, of which 60 were originally ordered, are in very great favour with the travelling public, who find them convenient to get into and easy in riding. These all have an open portion at each end, in which smoking is permitted, the only drawback being, from the smokers' point of view, that ladies frequently occupy these seats in the summer time to the exclusion of the smokers. These bogie cars are 40ft. in length, with 15ft. bogie centres, each bogie having equal sized wheels of 31in. diameter, and there are in addition 22 bogie cars of the same length, which have been built by the department, with double decks, and carry 102 passengers, these cars being principally used for meeting heavy rush traffic at any time. The single-deck bogie cars have two motors of 30 h.p. each, and the double-deck bogie cars four motors of smaller size. The remainder of the rolling-stock consists of four-wheel cars, a few of these being single-deck, and over 80 being double deck of the standard type, driven by two motors. The department is now building its own cars at the car works at Byker. The cars are housed in four car-sheds of various sizes, two of these being old tramway stables, the roofs of which were raised to give increased height, and two being new buildings of steel frames filled in with concrete walls. All are equipped with pits for the inspection of the mechanism of the car, and have the usual offices and messrooms for the staffs. In the car works at Byker a complete set of wood-working machines are installed, each driven by a separate motor, and there is a large machine shop provided with metal-working tools and a smiths' shop. To provide sand for the cars a special furnace with rotary scraper is provided, which evaporates the moisture out of the sand, it being then lifted by mechanical means into a riddle, where all the stones are taken out, and the sand is filed from hoppers into bags for supplying to the cars.

RHYMES FROM THE OFFICE.

BY PABLO.

No. 2.—The Slide-Rule.

He won me as a prize, and called me "fine";
Yet in his hands I'd many artful tricks,
And calculations weird were often mine—
Eighteen by three divided—answer, nine;
Or fourteen five times over—sixty-six.

In constant practice full perfection lies,
And now his slide no longer causes slips—
His rule's unruly spirit has grown wise.
No problem he by mental effort tries;
In ready reckoner he never dips.

As use is second nature, so he needs
My service for the simplest rule of three.
Unconsciously he takes me up and reads
My face when asked (nor vulgar laughter heeds)
If it will rain, or what he'd like for tea!

And when, sometimes, too soon five-thirty comes,
And he at home would fain sit working late,
Perchance I help—'tis one of nature's sums—
His youngest find the product of it's gums,
While he can only frown, and watch, and wait.

INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

Ninth Annual Convention.

(Continued from page 89.)

Following the reading of Mr. H. Faraday Proctor's paper on "Some Notes on the Bristol Electricity Works Fire," given in our last issue,

Mr. M. H. KILGOUR, of Cheltenham, complimented the author on his paper, and on his courtesy in inviting other engineers to see the results of the fire. He considered that the fire was caused by the improper action of a fuse due to the spring becoming stiff. It would then fail to draw the fuse wire under the oil. As regards the covers of these fuses, he had found it best to prop up these to prevent the explosive action when a fuse went. He considered the Ferranti board most excellent with the sole exception of the fuses, which should be replaced by automatic oil-break switches.

Mr. G. H. COTTAM, of Hampstead, raised the question as to whether the oil-pot was full of oil.

Mr. L. ANDREWS did not think the fire had started from static discharges over the surface of the slates. He was inclined to believe that a trunk main was the seat of the first fault, and that this caused the heavy current on the Temple Back generators. The fuse then started the fire. He referred to the variability of fuses, and said all their action were dependent on the point in the wave at which the current was broken.

Mr. C. H. WORDINGHAM, of the Admiralty, drew attention to the importance of having both the switchboard and the station fireproof. The switchboard gallery should be of expanded metal in concrete. Rubber mats were dangerous. He would like to know if sulphur compounds were used in and around the fitting of the fuse pots, as this was inflammable, and also it softened under heat, and thus tended to distort the fitting. Could the author tell them what fraction of the total loss had been paid by the insurance companies? As regards the cable insulation, he had tried copper-covered paper cables for special work.

Mr. J. H. CLOTHIER traversed the whole field of possibilities, and said that the coil used would not burn by itself He did not think the switchboard insulation had failed, as there was at least 2½in. of porcelain in the leakage path.

Mr. S. Z. DE FERRANTI first referred to the honourable way Mr. Proctor had dealt with the matter. His conclusion was that the fuse had failed, and this was the simple explanation. They had made several patterns of fuse pots, and it was hard to make improvements. The one at Bristol was the worst pattern of fuse ever made. Without doubt the spring had failed and left the ends of the fuse sticking up over the oil. He considered that the cellular pattern of switchboard had even then justified itself, as the fire would have been confined to three or four panels but for the surroundings of combustible material. Indiarubber mats were very bad, and he thought that a glass and iron construction for the switchboard gallery floor would be best. The lids, as one speaker had said, were a fatal adjunct to the fuse pots. The firm had advised the users of this, but some engineers used them to keep the dust out. It was the Grosvenor Gallery switchboard fires which led to adoption, 14 years ago, of the cellular type of board. He considered that fuses, while good for small currents, had been used much beyond their sphere of service, and should now give place to oil-break circuit breakers.

Mr. PROCTOR, in reply, was sure that the fuse pot was full of oil, and that a new fuse had been recently inserted. He did not fancy glass for a switch gallery, as it was liable to be slippery.

The two following papers were also submitted:

Boiler-House Economies.

BY REGINALD S. DOWNE, M.I.E.E., BOROUGH ELECTRICAL ENGINEER, SOUTHPORT.

The problem is to deliver a unit of electricity at the station 'bus bars with the minimum number of pounds of coal, and this question is the most difficult one the engineer has to face in the power-house, but the one most likely to give the best money return for the time expended on it. Numerous papers bearing on the economical use of coal have been read before the I.M.E.A. and the various institutions with which its members are connected. It is, therefore, a matter of some difficulty to add any information to what has already been written. To all engaged in central-station management the question is of such daily importance that all will agree the council has acted wisely in putting the matter forward at conventions from time to time, so that it may be fully discussed to the mutual benefit of all concerned. Coal in some cases accounts for 50 per cent. of the total costs. None of the items which make up the total costs of production, with the exception of coal, are capable of being materially reduced, as the economical limit has been reached. Any further reduction can only be brought about by increased output. One of the papers previously referred to was read by Mr. A. S. Giles, in January, 1904, before the Manchester Section of the Institution of Electrical Engineers. From data supplied by the chief engineers of a large number of central stations, Mr. Giles compiled a table giving particulars of coal consumption, load factor, etc., which has been with his kind permission attached to this paper (Table A). The stations here tabulated represent fairly well the best practice now prevailing in this country, yet the particulars given are so widely divergent that it is difficult to account for them. For instance, non-condensing stations with moderate load factor and low-priced slack consume 6·5lb. per unit generated, whereas there are condensing stations with similar priced slack and higher load factor consuming 10lb. and upwards.

Broadly speaking, the only conclusion one can arrive at after carefully studying the table is that the stations with the largest output and highest load factor appear to give the best results, and that the other contradictory figures must be due to local or special conditions unknown to engineers. A central station is run on a money basis, and all the conditions are carefully studied when the lay-out of plant is decided upon; one can therefore only work in the most economical manner, and introduce such improvements and modifications as will give a reasonable return on the capital outlay. Each separate station has to be dealt with on its merits, and the measure of success is the net saving in the coal bill at the end of the year. The great majority of stations burn bituminous slack, costing from 6s. to 12s. per ton delivered in the bunkers. Where the railway rate is high and smoke conditions stringent, Welsh coal is used; in a few cases where it is available, smudge or low-grade fuels are burned. This point is entirely settled by local conditions. Assuming bituminous slack is used, how many pounds ought to be considered the maximum necessary to generate a unit of electricity? In a well-designed condensing station, with economisers and superheaters, and having a load factor of not less than 15 per cent., in the author's opinion, with the experience at present available, it ought not to exceed 5lb. This quantity of coal should cover all the losses between the furnace and the engine. Several private industrial plants are now generating a unit of electricity with 3lb. of cheap slack. No comparison, however, can be made between the coal consumption of private plants and public supply stations, the nature of supply being totally dissimilar. The results obtained are excellent, but under the same favourable conditions one could do better.

Before this problem can be dealt with, it is necessary to know where the losses are taking place; are they due to low boiler efficiency, steam range losses, excessive steam consumption of engines, or all three? To enable this to be ascertained it is necessary to have a rigid weekly analysis of units generated, together with coal and water used. In most works completed quite recently provision has been made for these measurements, and it is possible to have a daily analysis which enables a close check to be obtained, and any discrepancies to be immediately looked into. A number of stations of earlier date are not so well provided in this respect. It is, however, possible for all to obtain the weekly consumption of coal, and thereby calculate the pounds of coal per unit generated. The measurement of water, unfortunately, is not such a simple matter; in many cases where the supply is not obtained from the town's mains it is not possible. Several stations have recently had water-meters fixed, in some cases to each boiler, and in others to the main feed ranges. The author has tried several types of meters fitted on the suction and on the delivery sides of the feed pumps, but found after a few weeks of constant running that water was passing without being recorded. It would be instructive to have the experience of those members who have water-meters at work as to their accuracy. In a large number of evaporation tests recently carried out by the author, meters have been discarded and two measuring tanks used instead. Where a duplicate feed range is available, tests of this character are quite simple. If it is not possible to isolate an economiser for the purpose of a test, hot water from the economiser delivery can be run into one tank whilst the other is being emptied, and pumped into the boiler at 190deg. to 200deg. F. The various directions and means through which one may still hope to effect a further reduction in our coal consumption are included in the

following list: (1) the influence of output and load factor; (2) bonus system for firemen; (3) superheating; (4) mechanical stoking and forced draught; (5) fuel analysis; (6) analysis of flue gases; (7) auxiliary plant; (8) feed water purification and heating; (9) prevention of radiation.

The Effect of Output and Load Factor.

The stations having the largest outputs and the highest load factors show the best coal results. The coal bill of a station in its early stages, before the output has reached a reasonable figure, is often abnormal, owing to its being ready to supply before there is much demand. The conditions are not favourable to economical running, as the fuel required for banking, keeping steam on ranges, etc., is out of proportion to the output. The effect of a bad load factor is more pronounced in the boiler-house than in the engine-room. Diagram 1 attached shows Southport curves of load factor, output, and pounds of coal per unit generated for the year 1903-4. With graduated sizes of units it is possible to run the generating plant in a fairly economical manner. A standing engine does not waste coal. According to Stromeyer: "Under ordinary working conditions the radiation from a boiler amounts to from 5 to 10 per cent. If we work a boiler only at half of its power the amount of radiation will still be the same, for the steam temperature is not altered, but the ratio of loss by radiation to heat put into the boiler is doubled. On the other hand, if a boiler is overworked, resulting, of course, in inefficiency of the heating surface, the relative loss by radiation is very much reduced." From this it appears conclusive that the number of boilers under steam should be kept to the minimum possible, and some method of assisted draught fitted to help us over the peak of the load. The author thinks it will be admitted that with the class of slack usually burnt, under natural draught, the boiler duty is much lower than the maximum; in many cases the number of boilers under steam could be reduced 25 per cent. The station with which the author is connected has Lancashire boilers, and the coal required for lighting and banking fires has been found in the winter months to amount to between 5 per cent. and 7 per cent. of the coal consumed. There was a difference of 2 per cent. in economy between banking fires on the 8ft. 6in. boilers,

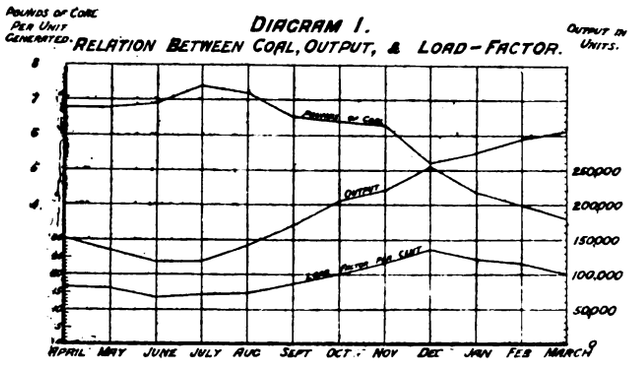
Digitized by Google

and allowing fires to die out on the 7ft. boilers, and *vice versâ*. A considerable amount of coal may be saved by finding out what banking conditions are most suited to the boilers at different periods of the year.

Bonus System for Firemen.

The personal factor in the form of the fireman has the greatest influence on the reduction of coal costs, after output and load factor. In a test quoted by Mr. Bryan Donkin, four good stokers were put to fire the same boiler—a two-flued 30ft. Lancashire—under the same conditions. There was a difference between the most and least expert of 23 per cent. in capacity and 18 per cent. in economy, a saving of £7 to £8 per week, with coal at 10s. per ton. All raw material from which there is no valuable by-product passes through the hands of the fireman. As a rule he does his best—*i.e.*, with a fluctuating load he draws a fairly straight line on a recording steam-pressure chart. He knows that the less coal he throws on, the less manual labour he is called upon to perform; he may also have a conscientious idea that by economising coal he is husbanding the national resources. Generally speaking, beyond that he has no incentive to economy, and provided he keeps a steady head of steam, is not interfered with. The man who actually burns the coal is the one who can effect the economies. When the managing engineer has convinced himself that there are no leakages through the brickwork, when the dampers are easily accessible, draught gauges have been fitted to the chimney and each boiler, and a CO_2 recorder has been fixed, he has done all that can possibly be foreseen, and the rest must naturally be left to the leading firemen.

A pecuniary incentive is a great help towards reducing the coal bill. If a central station has not reached what it considers its minimum coal consumption, it is worth while paying at least 2s. to save 20s. worth of coal, which it could not otherwise do. It would be interesting to know what results have been obtained by this means. At Southport a coal bonus has been recently introduced, and the following particulars have been added, as



they may be of interest to the members: the present contract price of coal is 7s. per ton delivered in the bunkers; the approximate number of units generated per annum = 2,327,600; the average number of units generated per week = 44,800; a saving of one-tenth of a pound of coal per unit generated on the averaged weekly output = 4,480lb. = two tons worth 14s.; per month of four weeks = £2. 16s.; the bonus is divided amongst the four leading firemen, and is distributed monthly; it has been fixed at 1s. per week per fireman for each tenth of a pound of coal saved—*i.e.*, for every 56s. worth of coal saved, 16s., or 28·5 per cent., is given as bonus. The pounds of coal below which a bonus is given has been fixed for the next financial year at 6·5lb. for the summer months and 5·5lb. for the winter months. If we have to pay more for our coal, the saving per ton is proportionately greater. Diagram 2 shows the bonus line at present fixed, and the pounds of coal consumed for each month during the past three financial years, the load factors being 14·22, 15·31, and 14·49 respectively.

Superheating.

No practical difficulties are experienced by using a moderate superheat up to 500deg. F. The saving in coal and steam may amount to between 10 and 20 per cent., and is greater where the engines are working under uneconomical conditions, and where a steam ring is in use, or the steam ranges are inordinately long. A superheater attached to a boiler may abstract 10 per cent. of the heat in the flue gases, and reduce the efficiency of the boiler by this amount; as this 10 per cent. extra heat in the steam may reduce the engine losses by 20 per cent. the net gain is very great, and alone would warrant adoption. The saving in steam is greater than the saving in coal, due to fuel being required to obtain the superheat. Tables in text-books show the great saving to be obtained in coal and steam consumption by even a moderate superheat. Many stations are now working with superheaters in side flues, which only increase the temperature some 50deg. F.; the gain in economy, though great, could be increased a further 5 per cent. by raising the superheat an additional 50deg. F. at the engine.

The author has superheaters fitted in the downtakes of all his Lancashire boilers, and has been able, by adding firebrick combustion chambers, to raise the temperature of the steam, leaving the superheaters from 80deg. to 150deg. F. Superheaters fitted in this way give a fairly constant degree of superheat, and require practically no attention. A consideration of the various types of superheaters is outside the scope of this paper, but the author is of opinion that where a high superheat of constant temperature is required (as in pure turbine stations) separately fired superheaters would be preferable. The following figures were obtained at Southport on two eight-hour tests carried out on a 250-i.h.p. horizontal Musgrave-Corliss condensing engine, supplied with steam from a 7ft. by 28ft. hand-fired Lancashire boiler with and without a Musgrave superheater:

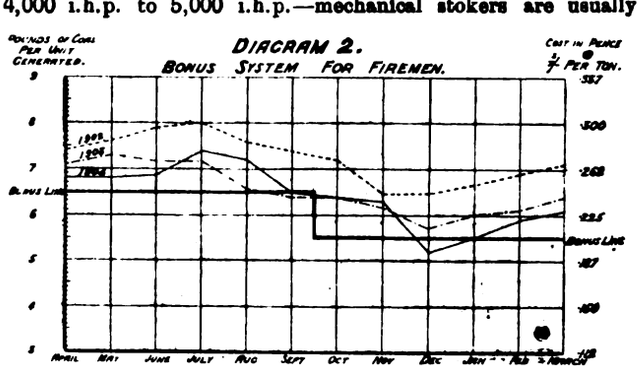
	Without superheater.	With superheater.	Saving per cent. in favour of superheater.
Water per I.H.P. per hour—lb.	16·30	13·58	17
Water per unit.....—lb.	29·27	24·24	
Coal per I.H.P. per hour—lb.	1·89	1·60	16
Coal per unit .....—lb.	3·40	2·86	

Average superheat at engine, 85deg. F.

At the time of this test a ring steam range was in use, which has since been discarded. A similar test if taken to-day would not show quite the same saving.

Mechanical Stoking and Forced Draught.

To what extent does mechanical stoking influence the coal consumption in central stations? Makers' tests do not help much, as they are not carried out under everyday conditions. Table A does not show that stations mechanically fired are more economical than those hand fired. In a large power-house having modern coal-handling plant mechanical stokers undoubtedly save labour, and where the load factor is high give economical results. In the class of station under consideration—viz, that having a total plant capacity not exceeding from 4,000 i.h.p. to 5,000 i.h.p.—mechanical stokers are usually



employed to enable bituminous coal to be burned with a minimum of smoke. Where the coal has to be thrown into the hoppers by hand there is no saving in labour, and it is doubtful whether any economy can be shown over hand firing when the interest, repairs, and cost of running are taken into account, while, on the other hand, there may be obvious disadvantages. The author does not wish to enter into a dissertation on the various types of coking or sprinkling, over-feed or under-feed stokers, but would be glad to elicit information from those engineers who have charge of hand and mechanically fired boilers, as to the economy or otherwise of the latter method of firing. As the furnace conditions are constant and uniform, there should be a saving, but from figures supplied to the author from various stations employing mechanical stokers, it does not appear to him that this is attained in practice. Many types of stokers require steam for cooling the bars, and in one station where this was tested it amounted to as much as 11·5 per cent., but this was afterwards reduced to 3 per cent. At sea, where the conditions do not lend themselves to mechanical stoking, good results are unquestionably obtained by hand firing. With but few exceptions, natural draught is depended upon for the combustion of fuel. Is it possible by adding induced or forced draught so to increase the evaporation and economy that after paying all charges there would be a saving that would be worth obtaining? A chimney is a rough-and-ready way of inducing the air to flow into the furnaces with sufficient velocity to cause the fuel to burn; it has the merit of being absolutely reliable, and the upkeep is nil. Energy must be expended in bringing the air to the coal, but as a chimney may require 20 per cent. of the heat units in the coal, this work may be carried out much more efficiently by other means.

The apparent advantages of forced draught are: (1) the steaming power may be increased 30 to 40 per cent. without injury; (2) higher temperature of combustion, giving a higher evaporative effect for the fuel; (3) air supply under control. Stromeyer in his memorandum (1902) states: "Perfect combustion is of far more importance, both as regards the efficiency of a boiler and the power to be got out of it, than is within

Digitized by Google

limits either the amount of heating surface or its arrangement." The furnaces usually fitted by boilermakers are only suitable for burning anthracite coal or coke. As the majority of boilers burn bituminous coal, the efficiencies are extremely low, but could be raised if the furnaces were designed to suit the class of fuel burned. In a coal containing over 10 per cent. of volatile hydrocarbon, a high temperature in the combustion chamber (approx. 1,100deg. F.) is absolutely necessary for combustion. In most furnaces, when the gases have distilled they immediately come in contact with water-cooled plates, and are reduced in temperature before combustion takes place. Until the temperature of combustion is raised sufficiently high, the thermal efficiencies of boilers burning this class of fuel will remain in the neighbourhood of 50 per cent.

Fuel Analysis.

It is essential that the quality of the coal used should not be frequently changed, otherwise firemen cannot obtain the best results. How can one ascertain that the quality of coal contracted for is being delivered? Some engineers argue that by buying the cheapest slack obtainable in the district, any deviation from the contract must be in their favour, but this method of procedure cannot always be recommended. Calorimeter tests of small quantities of coal, although fairly comparative, are not of much commercial value, because the thermal value of bituminous fuel is augmented by the hydro-carbons, a large proportion of which escape up the chimney without parting with their heat. The calorific value of some soft bituminous coal is equal to that of hard South Wales coal, but in practice the evaporation is much lower. If we obtain the percentage of moisture under similar weather conditions by drying a known weight of slack, and also ascertain the percentage of ash, it is possible to keep a reasonable check on the deliveries. In the author's opinion, evaporation tests made under similar conditions give the best practical results. Where a contract is placed with a colliery, fewer deviations in quality are to be expected than where supplies are obtained from a coal merchant or colliery agent; where the colliery works only one seam of coal the conditions are even more favourable. Southport has placed a contract with the nearest colliery under the latter conditions, and the following two tests carried out by Mr. J. B. C. Kershaw, F.I.C., on samples delivered over six weeks show the qualities to be practically identical.

Tests made on Sample after Drying.

Description of sample.	Per cent. moisture.	Per cent. ash.	Per cent. coke.	Per cent. volatile matter.	Per cent. fixed carbon.	Calorific value in Fahrenheit units.
Bickerstaffe slack "A"	8·48	11·00	68·60	31·40	57·60	13 879
" " "B"	7·73	10·85	67·35	32·65	56·50	13,848

Analysis of Flue Gases.

For a complete analysis of the exit gases from a boiler it is necessary to know their chemical constituents, temperature, and draught. This information enables the engineer to reduce the loss up the chimey to a minimum; apparatus for carrying out these tests is now available. To obtain the greatest boiler efficiency the excess of air must be kept as low as possible, and this can only be ascertained by individual tests, and depends upon the quallty of coal and the draught available. Every pound of air which passes through the boiler in excess of the theoretical quantity represents a dead loss, as this air has to be heated up from the temperature of the atmosphere to the temperature of the exit gases. To obtain perfect combustion of the fuel, as much oxygen as possible should combine with the carbon to produce carbonic acid. For practical purposes, the amount of carbonic acid produced is an index to the state of combustion. Under theoretical conditions without excess air, 19 per cent. CO_2 would be produced, but in everyday work one might with reasonable attention obtain 12 per cent. CO_2 with an exit temperature of 600deg. F. The difference between 8 per cent. and 12 per cent. CO_2 represents a loss of 8·5 per cent. of the fuel burned. Many works have recently fitted up recording apparatus to ascertain this percentage, and in most cases the results have been eminently satisfactory, and have well justified the outlay, This arrangement for analysing the gases is more convenient than the "snap" method, and the readings are for all practical purposes correct, but can be checked by direct analysis. It is possible to connect the apparatus to each boiler in turn, and by reducing the air leakages, altering the thickness of fires, etc., to raise the average percentage of CO_2 considerably. Without some apparatus of this character it is not possible to keep a close watch on air leakages. Most boilers are surrounded by a quantity of brickwork, which is notoriously porous, and as this brickwork is subjected to great changes of temperature, the air leakage becomes excessive unless it is receiving constant attention. Air leakages being inwards are of an insidious character, as they do not show themselves but have to be searched for.

When boilers are shut down under natural draught, there is always considerable air leakage into the main flue even when the dampers are closed. Sliding dampers require to be an easy fit in their frames, but in most cases this is overdone; an improvement on the usual type of damper might be easily fitted. The brickwork round damper-frames is difficult to inspect; generally on being opened up it is found to pass cold air at every joint. This air has a considerable cooling effect on the gases; it decreases the draught and lowers the economiser efficiency. To what extent this cooling is possible, is shown by the following figures taken by the author from a range of six Lancashire boilers, No. 6 being nearest to the economisers.

Boilers Nos. 5 and 6 under steam.
Temperature of exit gases taken in side flues at a point 12in. on boiler side of dampers.

Average temperature of exit gases	729deg. F.
" " in centre of main flue opposite No. 6 boiler	314deg. F.
Average temperature of gases entering economisers	496deg. F.
" " leaving economisers	291deg. F.

The stream of cold air leaking past the four standing boilers passing up the centre of the main flue and mixing with the hot gases from Nos. 5 and 6 boilers, reduced their temperature 233deg. in 10ft. of flue. The fall in temperature through the economisers was only 205deg. If it is not possible to prevent these air leakages at the dampers on shutting a boiler down for any length of time, it is advisable to brick up the furnaces. The author has had one form of CO_2 recording apparatus fitted in his boiler-house for the past eight months, and has found it extremely useful. When first installed it was impossible to get more than from 2 to 3 per cent. CO_2 from certain boilers; on tests he has since obtained 15 to 16 per cent. as a maximum, but the average daily running works out about 10 per cent. Two boilers, even after the brickwork had been thoroughly overhauled, would not give more than 3 per cent. CO_2. On further investigation being made it was found that there was an opening at the back dead plates, just behind the bridges, measuring 30in. by 3in.; this was a drastic remedy of the boilermakers for smokeless combustion. On bricking up these openings the CO_2 was equal to that given by the other boilers, and they naturally gave a better duty.

Auxiliary Plant.

Mechanical stokers, economiser scrapers, coal elevators, and ash conveyors are now generally electrically driven. Most stations, however, still have steam feed pumps which are notoriously inefficient, and may require from 2½ to 3½ per cent. of the steam generated. With a careful subdivision of electrically-driven feed pumps, this may be reduced to 1½ per cent. The first cost of the pumps is greater, but after meeting all charges there is a distinct saving, and they are as reliable as any other type of feed pump. It is, however, advisable to have a steam pump as stand-by in the event of any local or other failure of the supply.

Feed Water Purification and Heating.

An exhaustive paper, entitled "An Enquiry into the Working of Various Water-Softeners," by Mr. C. Stromeyer and Mr. W. C. Baron, was recently read before the Institution of Mechanical Engineers, dealing with the different impurities to be found in feed water and their effects on boilers, and the various types of softening and purifying apparatus at present to be found in the market. It is therein stated that "Scale does not materially reduce the efficiency of a boiler, but it seriously increases its wear and tear, whereby its life is considerably reduced; its also endangers the safety of boilers. The same remarks apply to coatings of grease due to feeding the boiler with water containing condensed steam from the engine. It is highly desirable to remove every trace of grease from the feed water. This cannot be done by filters, the only efficient method is to add mineral matter in solution to the condensed water, and then to cause precipitation by chemical means." In every case where water is treated it should be done externally before entering the boiler. For economical steaming a boiler should be clean inside and out, because the transmission of heat is rendered easier and the evaporation is increased. It is a generally accepted fact that no economy can be obtained by raising the temperature of feed water except by heat which would be otherwise wasted. Is it possible, by having separately fired feed heaters in series with economisers, to put the water into the boilers at the same temperature as the steam, and so obtain more duty per boiler, and reduce the number under steam, thus effecting a saving in coal? The true function of a boiler would then be steam raising and not feed heating in addition. Under existing methods the limit to which heating can at present be carried is to have an exhaust heater in the path of the steam, on its way from the cylinder to the condenser, and in series with it a heater which will utilise the exhaust steam from the auxiliary engines, the water afterwards passing through a third heater in the form of an economiser. The temperature to which the feed water can be raised has a decided bearing on the subject, as the economy resulting

Digitized by Google

from raising feed water from 150deg. to 250deg. F. is 10 per cent.

PREVENTION OF RADIATION.

When the boilers and piping have been covered with the most suitable material, it is necessary to have it periodically examined and repaired, as it is usually of a perishable nature. Where it is enclosed in a metallic envelope much waste may be caused if there is contact between the piping and the shield, which may be at nearly the temperature of the steam. Condensation may be reduced one half if the valve bodies and flanges are covered. The joint itself may be left exposed, but with superheated steam there is little trouble from leaky joints if the ranges are well drained.

CONCLUSIONS.

Perfect combustion of fuel cannot be obtained in any form of boiler, but it ought to be possible to considerably raise the low thermal efficiencies at which most of them are working at the present time. The two essentials are: the highest possible initial temperature in the combustion process, as the heat transmission between the water and the hot gases is directly proportional to their difference of temperature; and a high temperature in the combustion chamber, so that the volatile gases are not cooled down before combustion takes place. To obtain full value from bituminous coal is an exceedingly difficult matter, and the numerous papers which have dealt with this problem do not assist us much. The subject is usually dismissed as follows: "In a properly constructed furnace these valuable hydrogen units can be utilised to their full value, but time does not permit of going further into this matter." What engineers are seeking is the properly constructed furnace, suitable for the particular class of slack to be burnt. The author has carried out a large number of evaporation tests at different rates of combustion, and with different forms of combustion chambers, on hand-fired 7ft. by 28ft. Lancashire boilers. The evaporation per pound of coal from and at 212deg. F. varied from 6·62lb. to 7·17lb. Coal burnt per square foot from 33lb. to 17lb. Evaporation from 5,250lb. of water per hour to 3,900lb., and the superheat from 151deg. to 80deg. F. One boiler is fitted with steam blowers. On test 5,400lb. of water per hour was evaporated. After deducting the steam taken by the blowers, the evaporation per pound of coal was only 6·21lb. On a special test it was found that the steam jets when giving a draught equal to $\frac{8}{10}$in. in the ashpits required 340lb. of steam per hour, equal to 6 per cent. of the steam generated. The fine ash made by the ordinary furnaces, amounting to 3 per cent. of the coal burned, approximately 200 tons per annum, is dealt with by this boiler; it was found to have an evaporation value equal to one-half that of the slack. Under the conditions stated, in Southport they obtained an average evaporation of 7lb. of water per pound of coal, having a calorific value of 13,800 British thermal units. Their average combined boiler superheater efficiency, therefore, is only 52 per cent. Electrical engineers have made great progress in this special branch of steam engineering, due in great measure to the fact that they are the largest purveyors of energy in a form which is readily and accurately measured. Before the advent of electricity supply these investigations were entirely in the hands of marine and water engineers, who were restricted to measuring their energy in indicated horse-power hours, which is neither a convenient nor particularly accurate method. As this question is now being intelligently dealt with by electrical engineers all over the country, we may confidently look forward to great improvements in the immediate future.

The Financial Position of Municipal Electrical Undertakings.

BY COUNCILLOR H. J. BLAKEWAY, CHAIRMAN ELECTRICITY COMMITTEE, BOROUGH OF SOUTHAMPTON.

The rise and steady growth of municipal undertakings for the production and supply of electricity is a subject which occupies the thoughts of many of one's fellow members of public bodies. It is a subject that appears to have two sides—the technical, from the point of view of the consulting and resident engineer; and the financial, as it affects, or may affect, the pockets of the general body of ratepayers (apart from those who are customers of the undertaking) who are immediately concerned in both the present and future prospects, and whose interests have to be safeguarded. It may be urged that at the outset one is wrong in this statement, and that the interests of the engineers and that of the ratepayers who find the capital are identical. The author is open to conviction on this point, and while admitting that there is unity to a certain point, it does not appear to be continuous, or if the engineers generally are in such sympathy with the ratepayers, the returns which are presently alluded to rather show that they are not the first consideration. The author states at once that he has the utmost confidence in the energetic body of men, most of them members of the association, who have largely in their hands the destinies of municipal electrical undertakings, and gladly takes this opportunity from personal knowledge of bearing testimony to their skill, their shrewdness, and, what is also of paramount importance, their honesty. His criticisms must therefore not be considered as reflections on them or their abilities.

To excuse the object of this paper, the author has been a very active member of his Electricity Committee since 1899, and has seen their undertaking under all possible conditions and vicissitudes, and it is a deep interest in this and similar undertakings that has caused him to take up the subject. That the members may the more readily follow the argument, it may be pointed out that it is based on the table of costs as published in the *Electrical Times* No. 645, published Feb. 25, 1904. It will be seen that therein are the returns of 155 municipal undertakings, and the period covered by their work is from one to twenty years. In a subsequent issue of this journal completed returns were given, but while a few new installations were added, for some unexplained reason several were dropped out, and as the figures following were not really affected, the number specified is adhered to. The total capital expended by these 155 concerns amounts to £21,983,000, and, in passing, the author would ask, how much of this is at the present date productive? The gross profit or earnings of these 155 undertakings—mostly for the year under review—amounts to £1,333,000, or on an average on the capital employed of 6 per cent. It will be generally known that from this amount of gross profit, provision has to be made for capital charges in the shape of interest and sinking fund, which as a general rule will amount to 5½ per cent. The rate of interest may, and probably does, vary, but there is not doubt that it is properly paid. The sinking fund from the figures given seems open to some doubt, as it averages only 2·62 per cent. Those of us who know the term of years for which capital for municipal electrical undertakings is borrowed, and the life of much of the plant and mains, know how desirable it is that the operation of the sinking fund should be a first principle.

We now come to the net financial result of the year's trading, and to better appreciate the position the figures are given in detail for the different periods:

Year of working.	No. of towns.	Deficit.	No. of towns.	Surplus.
First	16	£18 398	7	£8,218
Second	18	20,715	8	5,771
Third	11	8,754	10	12,759
Fourth	4	2,921	8	6,594
Fifth	2	2,080	2	2,011
Sixth	—	—	9	14,789
Seventh	6	8,659	3	2,000
Eighth	1	399	20	69,103
Ninth	2	2,195	12	45,642
Tenth	2	6,040	1	2,648
Eleventh	—	—	4	47,055
Twelfth	—	—	3	1,385
Thirteenth	—	—	3	14,744
Fourteenth	—	—	—	—
Fifteenth	—	—	—	—
Sixteenth	—	—	—	—
Seventeenth	—	—	—	—
Eighteenth	—	—	—	—
Nineteenth	—	—	1	33,415
Twentieth	1	1,080	1	2,814
	63	£71,241	92	£268,948

Thus we see that 63 towns have a deficit and 92 a surplus, and to get a really correct idea of the net result of the working of municipal undertakings approximately to date, the author deducts the deficit from the surplus. This will show a net profit on the year's working of £197,707, or 0·9 per cent. on the capital outlay. If it be urged that this is an unfair conclusion to draw, he is quite prepared to admit that in the first and second years it is rather unreasonable to expect a profit, although the returns show that even this difficulty can be overcome. But what can be said for the other losses up to the tenth, and even the twentieth year. In connection with the surplus, it must be remembered that coal, the principal item, was at a fairly low price; it is not pleasant to think what the results would have been had it reached the figures of two or three years ago. On a capital, therefore of nearly twenty-two millions, some of which is practically dead, we thus have a sum of under 1 per cent. which can be devoted to a depreciation or renewals fund. How many of us have such a fund, and is the necessity of having one generally realised? As, however, the object of this paper is not to deal with a depreciation fund, this may be passed over. The author points out that he omits from his calculations a grant in aid of the local rates, as, in his opinion, before any of the surplus is used in this direction two conditions must be observed—viz.: (1) current for lighting must be sold at the lowest possible rate; (2) the renewals fund must stand at a proportionately substantial figure—and it is easier to provide for both these conditions in the "years of plenty."

The main object of this paper is to emphasise the fact that those running municipal undertakings are under an obligation

Digitized by Google

to safeguard the interests of the larger body of ratepayers, whose credit is pledged to find the capital, but who cannot, or do not, all equally enjoy the benefits of the concern, although in the event of losses they would be called upon to provide the deficiency. To further elucidate his contention, the author invites a careful study of the individual returns, and thinks, in many cases, the causes of the unsatisfactory financial results will be found in the charge made for traction and power purposes. It must be admitted that the main object of our undertakings is the supply of current for lighting purposes, and this at as low a rate as possible, for undoubtedly the lower the price the greater the demand, and a correspondingly greater financial success. There has, however, grown up a natural desire for a day load, a load that will employ plant and mains during an otherwise unproductive period. Current for tramway and power purposes has been the outcome of this desire, and the author expresses his opinion here that where electrical works are municipal and tramways likewise it is a matter for regret that separate works have been established, and the lighting works deprived of the benefits of the combination, an arrangement certainly not in the interests of the general body of ratepayers. Dealing first with traction: extra plant has usually to be installed, generally the stations have needed enlargement, and it must be apparent that as the traction load does not go off, but probably increases as the lighting load comes on, duplicate plant is unavoidable, and it is manifestly unfair that the tramway committees should not bear a proper share of the charges on the extra capital expended.

In the returns under notice, in too many instances, the rate charged is too low, and the combination really results in a loss. It must be remembered that equally with the tramways committees we must do the best we can for our undertakings, and this can only be done if every unit sent out from the station bears its proper share of the expenses of production. Stations with a traction load gladly avail themselves of the added units to reduce their costs, but they are not so keen on insisting that all such costs are covered. Quoting from one's own town, for the year under notice the total costs were 1·6d., and on the face of it current for traction purposes could be supplied, without profit, at this figure to a corporation department. The electric lighting department has, however, provided all feeder cables from station to section boxes, and had other considerable capital outlay for suitable plant, so that, allowing for capital charges on this work, it was bound to charge 2·25d. per unit, which provides a small margin. For the current year the price has dropped to 2·125d. This method of computation is a safe guiding rule, and the author suggests it is worthy of general adoption. To the ascertained or estimated total costs, add such capital charges as can be fairly allocated, and to the resulting figure, add a fair contribution for depreciation and renewals, but no profit. The price charged will rise or fall with the costs, the respective committees estimating accordingly, and thus treating each other fairly. If this were adopted, many of the financial results would show very different figures.

Coming now to the second part of the day load—viz., power generally—it is evident that the number of opinions relating to this are only to be measured by the number of installations. Despite the probability of causing many to differ from him, the author is bound to state his opinion, that in the majority of returns current for power purposes is being sold below cost, and without benefiting the station financially, or, indeed, doing anything beyond reducing, by the added units, the total costs. This is manifestly wrong, and almost immoral, and to prove that it cannot be done without loss one need only point out that many stations are actually selling current to the public for power at a lower rate than is charged to the tramways. This will take some explanation, as one or the other rate must be wrong, even making allowance for the fact that the lighting mains from which the motive power is taken are there in any event, while extra mains are put in for traction purposes. As in most stations it is customary to run one or more generators during the day for intermittent lighting, it is quite possible that up to a given point a few units could be sold at any price that will cover the coal consumption; but who is to decide when this point is passed and the load has grown to a greater extent, and not only grown, but continued in the winter months during the period of the peak load in lighting. By what process of reasoning, therefore, are these units to be exempted from bearing their proper share of the station expenses and capital charges? The author urges that they are not properly exempted, and a similar rule should be adopted as in the case of traction supply, only if in this instance it is not a corporation supply, there should be a margin of profit, and no current for any purpose whatever should be sold at less than the total cost of sending it out. Somebody has to pay; and if the power consumers are exempted, the customers of the concern for light, who are the mainstay and deserving of every reduction and consideration, have ultimately to suffer. Or if there is a loss, as there is in 63 installations out of the 155, the general body of ratepayers already referred to may be actually called upon to contribute to the working expenses of the industries of the district—a state of affairs which few of them realise, and which they should not tolerate. Such a position may result in a new order of "passive resisters."

A word on public lighting may not be considered amiss in this connection. Referring again to the returns, we find a load that is as profitable and productive as any that can be had. But why do so many stations handicap themselves by actually charging a higher rate than for power, and thus prevent further public lighting being added to their supply? This is another proof that the power rate is insufficient. The same rules should apply in this case, and the same methods of computation. Let us light our streets as well as we can and as cheaply as possible, but where the local body has an electrical supply it should have the greater part of the lighting, especially of the main streets, and the charge should be at a price similar to that made for traction and power purposes—certainly not more. This question has been dealt with from the point of view of a ratepayer, who is also chairman of an undertaking which, like all others, must be run for the general benefit. Unless we are all careful and prudent, we shall find our capital expenditure grow beyond a remunerative point; we shall also, in the more or less near future, have to face, within the periods of our borrowing powers, heavy renewals, and the points raised in this paper are crystallised in the question, *Will our present and prospective revenues on their present basis meet the demand?*

OLDHAM ELECTRICITY ACCOUNTS.

The accounts of the Oldham Corporation electricity department for the year ended March 25, 1904, show a total expenditure on capital account of £242,974. Abstracts of the revenue account, balance-sheet, and statement of electricity generated, sold, etc., are appended.

Dr.	Revenue Account.	£	s	d.
Generation of electricity		9,717	15	11
Distribution of electricity		669	9	2
Rents, rates, and taxes		1,625	19	4
Management expenses		1,050	8	6
Law expenses, commission, etc.		162	4	8
Insurance and bad debts		95	14	9
Balance carried to net revenue account		13,002	15	4
		£26,324	7	8
Cr.		£	s.	d.
Sale of current per meter		11,641	18	3
Ditto public lighting		180	17	3
Ditto traction purposes		13,608	3	8
Rental of meters and indicators		386	10	0
Sale and repairs of lamps and apparatus		140	12	4
Rental of land and fine		16	6	5
Income tax deducted from chief rents paid		18	2	0
Ditto from interest on loans		331	18	0
		£26,324	7	8

Dr.	Balance-Sheet.	£	s.	d.
Capital account—amount received		236,269	8	11
Sundry creditors		6,896	15	6
Balance at credit of net revenue account		389	15	10
Balance at credit of sinking fund		6,297	9	9
Balance at credit of reserve fund		9,180	4	5
Deposits		92	10	0
Balance due to treasurer on general account		12,746	9	0
		£271,872	13	5
Cr.		£	s.	d.
Capital account—amount expended for works		242,974	1	10
Stores on hand		4,792	19	6
Sundry debtors		8,627	17	11
Balance in treasurer's hand		15,477	14	2
		£271,872	13	5

Statement of Electricity Generated, Sold, etc.

Quantity generated in B.T. units			3,330,291
Quantity sold	Public lamps	17,362	
	Private consumers by meter	848,095	3,042,766
	Traction purposes	2,177,309	
Quantity expended in distribution			55,512
Quantity used on works			197,000
Total quantity accounted for			3,295,278
Quantity not accounted for			35,013
Number of public lamps			20
Total maximum supply demanded (kilowatts)			1,765

Outing.—On July 13 the staff and employés of the Urban Electric Supply Co., Dartmouth, about 30 in number, had their second annual outing, and drove to Newton Abbot, Chudleigh, Egbrook Park, Little Haldon, and Black Forest to Stareross. At a dinner there, Mr. H. C. Babb, on behalf of the whole of the employés, presented Mr. G. E. Smith, the manager, with a very handsome smoker's cabinet as a token of their high esteem and respect. Afterwards, Dawlish and Teignmouth were visited.

Bound Volumes of "The Electrical Engineer," *containing half-year's copies, bound in Dark-Blue Cloth, Gold Lettered, price 8s. 6d. New Volume, January to June, 1904, now ready.*

CORPORATIONS v. TRAM COMPANIES.

An important judgment has been delivered by Mr. Justice Phillimore in the case of the Norwich Corporation *v.* the Norwich Electric Tramways Company, which will have a far-reaching effect. The crux of the case is simple—relating as to which party should maintain the road immediately adjacent to the granite setts of the tramway in repair. Everybody knows that the granite setts of the tramway wear at a very different rate to any macadam surface adjacent to those setts, and frequently in a very short time a rut, deeper or shallower, according to the nature of the traffic, is formed at the junction of the two road materials. All manner of dodges have been tried to minimise this trouble, but it remains, and must remain as long as two different road surfaces with different wearing qualities are used next to each other. Even by using one material for the whole road surface the trouble is merely reduced, not avoided. To keep a road surface efficient which contains lengths of steel rails, granite setts or wood setts, and macadam is a problem as yet unsolved. According to present knowledge, it cannot be done. In a short time, whatever the materials used, ruts are formed near to rails, but these are usually neither so deep nor dangerous as those formed at the junction of setts and macadam. Directly a depression is formed the skew action of wheels leaving the setts to get on to the macadam rapidly increases the depression, and this has to be taken into account, as well as the difference of ordinary wear and tear. The Norwich Corporation is blessed with a very able and experienced city engineer, who is responsible for the due maintenance of the roads and streets of the city. Whether due to his foresight—as we may reasonably assume it was—or to some other cause a clause was inserted in the Norwich Tramways Act intended to define which party—Corporation or tramway company—should pay for the work and materials required to keep these ruts from becoming dangerous. The clause is—Section 57, Sub-Section 5—as follows: Section 57: "If the company fail to maintain," etc. Sub-Section 5: "The junction of the paving laid and maintained by the company, with the surface laid and maintained by the Corporation," etc. The vital point in the dispute was the interpretation of the word "junction." The Corporation held, and successfully held, that it meant the company should maintain the material area close to the setts free from dangerous ruts. In order to get a legal decision upon the point, the Corporation did some work and sued the company for the amount, and asked for a ruling to define clearly the principle involved. Declarations were prepared by each party, and with a slight modification that of the Corporation was accepted by the learned judge. It will perhaps elucidate the principle involved if we quote the judgment on this point. The learned judge said: "With regard to the proposed declaration, he had asked each party to suggest in writing the form it should take. These forms had since been sent to him. That proposed on behalf of the Corporation was as follows: they asked for a declaration 'That the obligation of the company under Section 57, Sub-Section 5, of the Norwich Electrical Tramways Act, 1897, to maintain and keep in good condition the junctions therein mentioned, extends to cases where, by reason of the presence of the tramways in a road, the traffic in such road has caused the surface laid and maintained by the Corporation to become worn down below the level of the paving laid and maintained by the company, and involves the maintenance by the company of a uniform level of such surface immediately adjoining such paving or the lowering of the paving itself.' On the other hand, the defendants asked for a declaration 'That the

Digitized by Google

true meaning of the word "junction" as set forth in Section 57, Sub-Section 5 of the Norwich Electric Tramways Act, 1897, is the line of contact formed—viz, the abutment of a vertical plane—that is to say, over the surface of the paving laid and maintained by the company upon a horizontal plane—that is to say, the surface laid and maintained by the Corporation—and the right of the plaintiffs to do and charge for the work under the said sub-section does not arise until and unless the level of the paving laid and maintained by the company at its point of junction with the surface laid and maintained by the Corporation varies from the level at which such paving was originally laid.' This last paragraph aptly expressed the contention of the company, and which he had rejected. As to the form proposed by the Corporation, he observed that it somewhat narrowed their claim. It proposed that the duty should only arise when, by reason of the presence of the tramways, the traffic had caused the surface of the roadway to become worn down below the level of the tramway structure. In other words, the duty would not arise as soon as a step was formed, but only when the guiding ridge was made a trough. To such a declaration as this the plaintiffs were fully entitled in his opinion, but he did not agree that the obligation of the company involved the maintenance by the company of a uniform level. It would mean the whole lowering of the tramway structure, or the raising of the whole macadam at once. What was meant was an unbroken contour, or levelling off for, perhaps, three inches, so that there should be no sharp descent. On the whole, he thought 'an unbroken contour' should be substituted for the words 'uniform level,' and with this alteration he accepted the form proposed by the Corporation; and he declared accordingly, plaintiffs to have the cost of the action."

This decision seems to agree with business principles. It is certain that the determining factor in breaking the contour over this particular area is the putting down of setts, and this is for the benefit of the tramway. The benefit of one should not in such a case be at the detriment of another, hence the cost of keeping an unbroken contour should be borne by the beneficiary. Fortunately for many companies—unfortunately for the ratepayers—a similar clause is not found in most Tramway Acts, but for the future it is certain to be included.

GLASGOW TELEPHONES.

We have now received the printed report of the Glasgow telephone service, but we prefer to deal with it fully in our next issue rather than to treat it casually now. It is far too important a document to be considered lightly; and, so far as we can see, the figures carry out to the full the contentions which have been made and are being made on behalf of the Glasgow authorities.

FORTHCOMING EVENTS.

FRIDAY, JULY 22.

Junior Institution of Engineers.—At 3.15 p.m., visit to Messrs. Bryant and May's factory, Fairfield Works, Bow.

Institution of Mechanical Engineers.—At 11 a.m., general meeting. "Design and Test of a Modern Steam Power Plant," by Mr. E. G. Hillier.

WEDNESDAY, JULY 27.

Society of Engineers.—Visit to Messrs. Yarrow and Co.'s shipbuilding and engineering works at Poplar; 1.52 p.m. from Fenchurch-street.

British Association.—At Cambridge, week commencing Aug. 17.

ARTIFICIAL LOADS FOR THE DISSIPATION OF ELECTRIC POWER.

BY F. H. DAVIES.

Of all central-station auxiliary apparatus that is not generally included in the main contract, the artificial load is, perhaps, the most important. In the days of small sets and more or less haphazard methods it was not given much thought. Some electricity works boasted sets of large and expensive resistance frames, which, constructed of steel tape or large slabs of some resistance material, were capable of dealing with 50 kw. or so, and the rest had recourse to the homely tub fitted with two lead plates and filled with a saline solution of some sort. The resistance frame for dynamo testing has had its day, but the tub in series-parallel arrangements still exists in a surprisingly large number of electricity works. With the comparatively large sets in use at the present day an artificial load is an obvious necessity, and it is safe to say that due regard to reliability and freedom from risk necessitates the trial running of a set at something approaching full load for at least a few minutes after a repair of anything but a trifling nature has been performed on it. More especially is this the case in alternating works, owing to synchronising difficulties. In direct-current stations it is often customary, say, after a bearing has been remetalled, to put the machine on load, at the same time watching carefully for any signs of heating, and being ready to change over sharply if necessary. Here this practice is fairly safe, as changing-over operations, even with large sets, may be accomplished in a very short time, but in alternating work this is not always the case, and the precious moments spent in synchronising have to be taken into account.

The attitude of the larger electricity supply concerns may be taken as indicating that the necessity of a preliminary full-power run is appreciated, for practically all arrange for a test upon artificial load after any repair of a serious nature, but the obsolete manner in which this is often carried out is surprising, and hardly creditable to those concerned. Quite recently one of the largest London high-tension electricity works afforded an exhibition to the passer-by of an alternator of some 500 kw. being run on a weird and wonderful arrangement of tubs placed in the station yard. High-tension cables strung about anyhow, no one to guard the apparatus, and no precautions for safety taken beyond a few half obliterated notices reading "Danger, 2,000 volts." This is not economical, it is not convenient, and it is certainly not safe. It is, perhaps, an extreme case, but very similar ones must be known to many.

Tubs as an artificial load even for the smallest sets are not convenient, and for large powers, in a short time of regular use, absorb enough money in the shape of wages for the men that dance attendance upon them to fit up a proper and permanent arrangement, and this in addition to the extreme inconvenience experienced in their use for dissipating considerable amounts of power. In all alternating and in every direct current works of any size, it will be found to pay to instal a properly designed and permanent water load, and the apparatus being simple in the extreme, this may generally be done at very little expense.

Before starting out to design a suitable arrangement, there are one or two points that must be considered and appreciated. Primarily, the passage of either alternating or direct current through water produces heat, and this lowers its resistance very considerably as boiling point is approached. It therefore follows that for convenient working the water must be continually renewed in order to maintain its temperature and conductivity at some fixed and suitable point. Then the nature of the water must be taken into consideration, for although the specific resistance of supply companies' water may be much the same all the world over, that of rivers and canals may be very different, the same stream even varying considerably according to the period of the year and the amount of impurities or refuse contained in it. This is especially the case with sluggish canal water; in the winter, when it is comparatively pure, its resistance is fairly high, but the advent of hot weather and putrescent matter lowers it greatly, some-

Digitized by Google

times to an almost incredible amount. The writer may cite a case in his own experience where the matter of one of the London canals varied so largely in conductivity at different periods of the year that while in winter a 2,000-volt alternator would be tested with the electrodes about three or four yards apart, in summer it was necessary to increase this distance fourfold to obtain an equal dissipation of power with similar electrodes.

The accompanying curve (Fig. 1) shows the results of a test made to determine the nature of the above-mentioned use of conductivity with heat. The water was taken from the mains of the New River Company, and the test, lasting 2½ hours, with no fresh water added to keep down the temperature, was with direct current at 500 volts. It will be seen that up to a certain temperature the rise in current and heat is proportionate; after this, however, the former gains rapidly on the latter. The results, as far as the actual figures go, are, of course, of no definite value, as these will vary considerably according to the volume of water in the tank, and, to a certain extent, with the size of the electrodes employed. They, however, demonstrate the fact that the rises do not take place in equal proportion for any length of time, and the ratio will very probably be similar for every class of water within reasonable limits. If desired, an increase in conductivity may be obtained by the addition of chemicals such as sulphuric acid, salt, and common soda. Of these, the two latter are preferable, being cheaper and having less corroding action on the

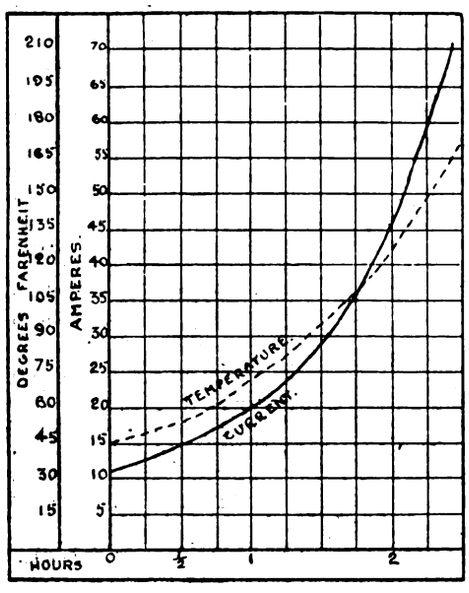

FIG. 1.

electrodes; but it is desirable, if possible, to do without them, as unless the addition is made very carefully after the water has attained its maximum heat, there is a likelihood of its being overdone, and the arrangement rendered temporarily useless by the resistance having become too low.

The design of a permanent water resistance, as far as dimensions go, must, of course, be dependent upon the size of plant to be tested; but in any case it is better to err on the large side, as the greater the volume of liquid the more satisfactory will be the results. If a water rheostat is overloaded, the resultant violent boiling gives rise to vapour troubles, and an unsteady current owing to the level of the water immediately surrounding the electrodes being constantly varied by the ebullition. A very simple arrangement suitable for dealing with up to 1,000 kw. at 500 volts direct current is shown in Fig 2. Both tanks are of iron, and the inner one, which is suspended from some suitable bracket by wires, is bottomless. The immersion of this latter is regulated by aid of a small winch—preferably one of the ratchet type—and by this means the amount of current can be regulated to a nicety. It is fitted with two bars of wood, on to which the suspending wires are fixed, being broken in their length by a series of insulators. These beams have an additional function—viz., that of preventing a short-circuit should the wires break. In working with tubs or other rough apparatus, it is common practice to suspend the electrodes by the cables themselves, the idea being partly that if the wire breaks, thus causing the two opposite poles to come into contact, the current will be automatically cut off; but such a system practically debars the use of winches, unless of special and elaborate design. It is on the whole better practice to use a strong steel rope, making sure that it is always fit for its work.

To return to Fig. 2: the positive pole of the machine is connected to the inner tank by a flexible cable, and the negative to the outer, which is earthed, the apparatus thereby being made to all intents and purposes safe. An efficient supply of cooling water is arranged for by the two pipes at the ends of the outer tank; the outlet should be at the top to allow the hottest water to flow off and the inlet at the bottom, thus causing the cold water to intermingle with the entire contents of the tank. If the supply is drawn, say, through the station circulating water mains from some adjacent stream, the hot overflow is probably of no value, and may be allowed to run to waste; but if, on the other hand, it is taken from the supply mains or other comparatively pure source, and not treated with chemicals in the tank, it may with advantage be passed

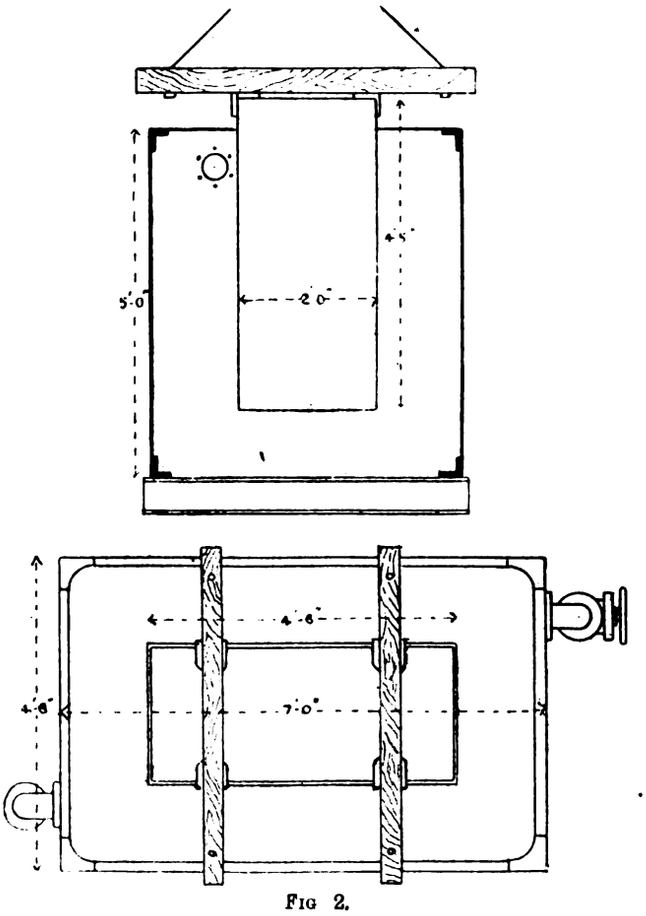

FIG 2.

into the hot-well, and an appreciable economy thus effected.

For testing high-voltage alternating-current machinery of the same output, the arrangement shown in Fig. 2 would be too large, but it may be adapted by substituting rod electrodes, the outer tank being earthed and simply used as a container and not as one of the poles. Single-phase work will necessitate two ¾in. or 1in. iron rods placed about 3ft. apart for 2,000 volts; and three-phase, of course, calls for three placed equidistantly at an angle of 120deg. Two-phase testing requires two separate tanks with two poles in each, the phases being treated separately as two independent single-phase circuits. One large tank such as the above may be used with only two inner electrodes and the tank as a common third, but in this case if accurate readings are required, say, for the purpose of an efficiency test, it must be divided between the two rods by a metallic plate electrically connected to the tank all round, as otherwise considerable current that obviously cannot be metered will pass between the two inners, falsifying the results to a large degree. When using rods as electrodes, it will be found

Digitized by Google

advantageous, in the interests of circulation of the water, to place earthenware drain pipes around them, with their upper ends slightly below the surface of the water. The violent boiling that takes place within the pipes owing to the restricted volume of water, causes a very rapid circulation upwards and over their tops, and this, of course, tends to the desired effect of keeping the whole of the contents of tank at approximately even temperature.

There can be no doubt that for the testing of machinery and for general station work, the water load is the best and handiest medium. Other types are, however, found in use, some of which may be recommended for purposes apart from machine testing. The carbon rheostat as a power absorber is an old friend—indeed, one of the first, and although it is not much used at the present time, it has done yeoman service in the past. The best form is the well-known one that is made up of a series of carbon plates placed in a frame fitted with a screw for tightening up or slacking back, the contact between the plates being thus increased or diminished, and the resistance of the whole varied in proportion. In this apparatus the resistance is due, not so much to that of the carbon itself, as to the more or less bad contact between the plates; and as these cannot be fitted or screwed up so as to touch equally all over their surface, the current is often forced to take a diagonal path through the plates from one point of contact to another, and by this means the resistance of the whole is considerably increased over the theoretical amount that might be calculated for the particular length and diameter of the rheostat. Cooling is the chief difficulty presented by such apparatus, and for this reason it is only suitable for very small powers.

A very cheap and handy form of artificial load may be made up of galvanised iron netting wound into a spiral by the aid of non-inflammable insulating distance pieces, or folded backwards and forwards over an iron frame built up on insulators. The resistance of this netting is approximately ·0036 of an ohm per yard of No. 18 gauge, 1in. mesh, one yard wide, and the safe current capacity of such a piece would be about 100 amperes. Different makes of netting would doubtless vary in these figures, and before building up such a rheostat careful resistance measurements of a sample would be necessary.

For testing small machines, such as exciters, a very handy artificial load may be made in this way. As a dissipator of heat, iron netting is naturally very effective, especially the kind composed of a right-angled mesh, in which case only one set of wires will carry current, while the others at right angles will serve to carry off much of the heat generated. Expanded metal also makes a very effective resistance, and in many ways is preferable to netting, being, for instance, stronger and requiring less support. It is, of course, dearer than the former, but to a certain extent makes up for this by requiring less in the way of holding up and clamping together. If intended for a permanency, its use is to be recommended over netting, but as a temporary expedient the latter is preferable owing to its extremely low cost.

THE WORKING OUT OF INDICATOR DIAGRAMS.

BY H. E. HODGSON.

The most important information sought from an indicator diagram is the indicated horse-power of the engine from which it is taken. The indicated horse-power of an engine, or the rate at which it receives energy from the driving agent, is measured by the amount of mechanical energy given to the machine in foot-pounds per minute, divided by 33,000. If we let

P = M.E.P. (mean effective pressure on the piston in pounds per square inch);
L = length of the stroke of the engine in feet;
A = area of piston in square inches;
N = number of useful strokes per minute;

then the work done during one stroke = P A × L, and the work per minute = P A × L × N; then the

$$\text{I.H.P.} = \frac{\text{PLAN}}{33{,}000}.$$

The length of the stroke is best measured by making a mark on one of the cross-head guides at each end of the stroke, and measuring the distance between the two marks. The piston area is obtained by removing one of the cylinder covers and measuring the diameter of the cylinder by means of a special form of micrometer calliper. The piston area being equal to ·7854 × the square of the cylinder diameter, of course the effective area on the crank side will be less than that on the head side by an amount equal to the sectional area of the piston rod. It is due to this difference in piston area that the indicated horse-power for the two sides of the piston have to be worked out separately.

The number of useful strokes per minute for one side of the piston in a steam-engine is equal to the number of revolutions that the engine is making per minute, and may be measured by means of some form of tachometer or speed counter. In a gas or oil engine the quantity N will represent the number of explosions per minute. To find the mean effective pressure, the diagram must be "averaged," or, in other words, the mean height must be found. There are numerous methods of doing this, some of which are briefly described below. The quickest and most accurate are those which involve the use of some form of planimeter. Unfortunately, this necessitates the use of a costly instrument which may only be occasionally used, and hence a more laborious method has often to be resorted to, known as the ordinate method.

Methods of Finding the Mean Effective Pressure.

1. *The Coffin Averaging Planimeter.*—The Coffin averaging planimeter (Fig. 1) consists essentially of a rod, T, having

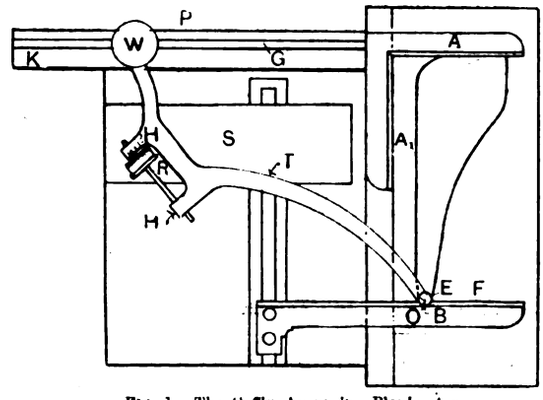

Fig. 1.—The Coffin Averaging Planimeter.

at one end a pin, P, constrained to move in a straight groove, G, in the metal plate, K, and at the other a tracing point, O. A small weight, W, is placed immediately above the pin, P, to prevent it jumping out of the groove. The rod is provided with two projecting horns, H H, which carry the bearings of the spindle carrying the flanged recording wheel, R, which runs on a specially prepared surface, S. The wheel, which is graduated, is provided with a vernier fixed to one of the horns for more accurate reading. To obtain the mean height of an indicator diagram, slide the card under the two clips, A B. Arrange it so that the back pressure line is parallel to the edge A_1 of the clip, A, and the left-hand end of the diagram touches the other limb of the same clip. Now push the clip B towards the clip A until it touches the right-hand end of the diagram, as shown in the figure. Place the planimeter in the position shown in Fig 1, with the tracing point at the point E where the clip B touches the diagram, and press the handle of the tracing point so as to mark the card at E. Then raise the wheel off the paper, by placing the finger under one of the horns, and set it to zero, care being taken not to touch the flange, which is liable to be rusted by the moisture of the hand, which would wreck the instrument. Some people prefer to take the reading at starting rather than setting the instrument to zero. The outline of the diagram is then carefully traced in a *clockwise* direction until the tracing point reaches E again. Now slide the tracing point outwards along the edge of the clip B until the wheel indicates zero or the initial reading; the tracing point will then be at some point such as F. Then E F is the mean height of the diagram. To find the mean effective pressure, measure the distance,

Digitized by Google

E F, with a scale corresponding to the number of the spring used in the indicator.

2. *The Amsler Planimeter.*—The Amsler planimeter consists of a rod, R, carrying a tracing point, T, this rod being joined to a radius bar, S, having a pivot, P, at one end, by

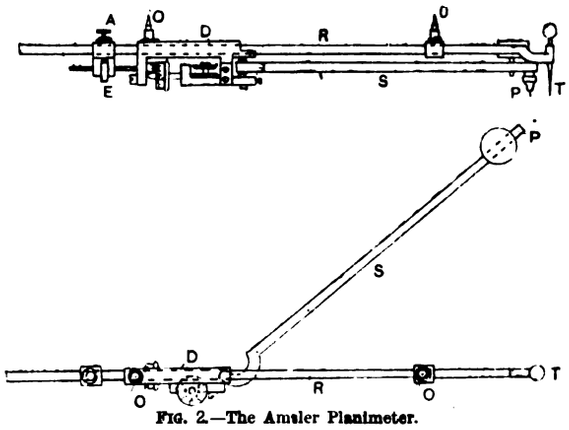

FIG. 2.—The Amsler Planimeter.

means of the saddle, D. The saddle, which is secured to the tracing arm by means of the clamping screw, A, carries the recording gear. It is preferable to use the instrument on a drawing board covered with a sheet of smooth, hard drawing paper.

Method of Use.—Unloosen the clamping screw, A, and run the saddle along the arm, R, until the distance between

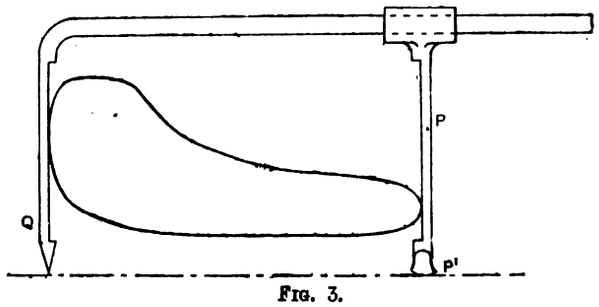

FIG. 3.

the two points, O O, equals the length of the diagram, the fine adjustment being accomplished by means of the milled head, E, after the clamping screw, A, has been tightened. Place the pivot point, P, of the radius arm at some convenient point on the paper and make some sort of mark on the outline of the diagram. It is advisable to commence

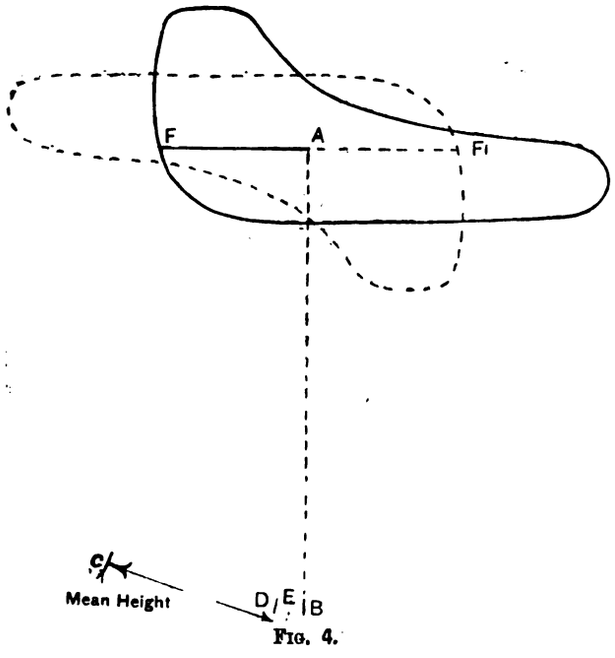

FIG. 4.

tracing a little distance to one side of this mark to obviate any slight error due to backlash in the recording gear. Take the reading of instrument when the tracing point, T, reaches the mark, trace right round the diagram, and take the reading again. The difference between these two readings divided by the constant of the instrument (40) multiplied by the scale of the spring will give the mean effective pressure.

3. *The Goodman Averager.*—Another form of instrument for obtaining the mean height of a diagram is Prof. Goodman's modification of the "hatchet" planimeter. This instrument is curious in its simplicity, consisting of a bent bar, Q, and an adjustable limb, P, held in place by a spring. The extremity of the movable arm is flattened out to form a knife-edge, P' (Fig. 3), the plane of which passes through the tracing point, Q. This intrument is totally different from the previous two, inasmuch as there is no wheel or recording gear at all, an ordinary scale being used for the ultimate reading.

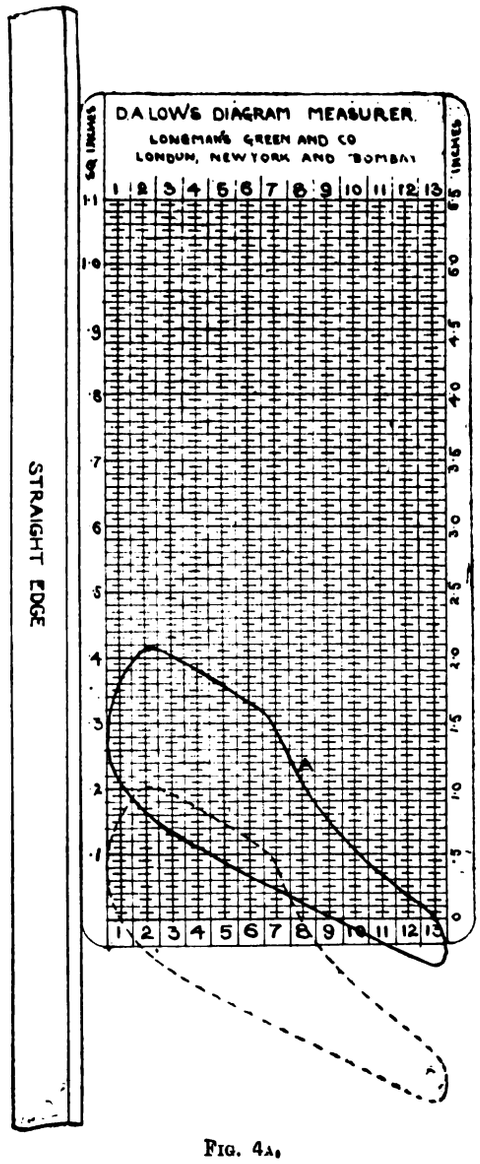

FIG. 4A.

Method of Use.—Run the movable leg along the bar until the distance between the legs is equal to the length of the diagram as shown in Fig. 4. Mark, as near as can be estimated by the eye, the centre of gravity (A, Fig. 4) of the figure, and from it draw a line, A F, parallel to the atmospheric line, to the boundary of the figure. Place the instrument along a line approximately at right angles to this line, with the tracing point at A and the hatchet at B, as in Fig. 5. Make an indent at B, trace right round the figure back to A, and make another indent at C. Then, keeping the instrument still, turn the card through 180deg. and retrace the diagram in the *opposite* direction, and make another indent at D. The points B and D should coincide, but due to the fact that the centre of gravity, A, was estimated in the first instance, and other small errors, they in general do not, so a point, E, is selected midway between them. Then the distance C E, measured with a scale corresponding to the spring used, will give the mean effective pressure. It is absolutely necessary when using this instru-

Digitized by Google

ment to keep it in a vertical plane, and allow the hatchet to run on a sheet of smooth drawing paper.

4. *Low's Diagram Measurer.*—Excluding planimeters, the easiest method of averaging a diagram is by means of Low's diagram measurer. This handly little instrument, designed by Prof. D. A. Low, of the East London Technical College, has lately been placed on the market by Messrs. Longmans, Green, and Co., the cost being the modest sum of 1s It is undoubtedly a useful instrument to possess, for by its aid the mean effective pressure of fairly open, clear diagrams can be determined almost as quickly as with an expensive planimeter. Although perhaps not quite so accurately as with a planimeter, yet the accuracy attainable with a modicum of practice and care is more than sufficient for all practical purposes. The instrument consists of a piece of transparent celluloid about 6½in. long and 3in. wide, upon which is printed two series of equidistant parallel lines intersecting each other at right angles, as shown in Fig. 4A.

Method of Use —Place it on top of the diagram to be measured, so that the two boundary lines touch the diagram, as shown at A in Fig. 4A. If the diagram is not large enough to stretch across the whole width, a portion may be used, or if too large, it may be divided into two parts, and the area of each found separately. Then, holding a straight-edge in the position shown, slide the instrument upward till the lower end of ordinate No. 1 is on the lower boundary of the diagram, as shown dotted in Fig. 4A. It will be observed in the example illustrated the first ordinate cuts the boundary again at ·16; the area of the first strip is, therefore, ·16 square inches. Next place a needle point at ·16 on ordinate No. 2, slide the instrument downwards till the needle point comes over the lower boundary; the reading where the second ordinate cuts the boundary will give the combined area of the two strips. These operations should be repeated for the other remaining strips. However, the number of strips that can be treated in this way is limited by the length of the instrument. If the sum of the first five strips falls just within and the sum of the first six falls without the limit of the instrument, then make a note of the area up to the fifth strip, and still keeping the straight-edge in the same position, slide the instrument upwards until the lower end of ordinate No. 6 is immediately over the lower boundary, and process as before. Proceeding in this way the total area of the diagram can be found; dividing this by the length of the diagram (measured on the scale provided on the right-hand side of the instrument), the mean height of the diagram is obtained, which, multiplied by the scale of the spring, will give the mean effective pressure.

(To be continued.)

TRADE NOTICES AND NOVELTIES.

Single-Phase Motors.

From the Langdon-Davies Motor Company, Limited, 101, Southwark-street, London, S.E,, we have two sheets giving particulars and prices of their single-phase motors with a spur gear speed reduction attached, or with a friction clutch attached. The spur gear gives a cheap and compact method of speed reduction, while the company's pattern of friction clutch enables the load to be thrown on and off the motor as gradually as may be desired. This is often of great importance when the motor is driving heavy machines, since the sudden throwing-on of the load, such as occurs with automatic friction clutches, is apt to pull up the motor, or, at all events, to seriously overload it.

Superheated Steam as Applied to the Willans Engine.

Some useful information concerning the use of superheated steam with the Willans engine is contained in a pamphlet recently issued by Messrs. Willans and Robinson, Limited, Victoria Works, Rugby. Several diagrams are included, showing respectively the saving effected in steam consumption on Willans triple-expansion, compound, and simple engines with varying degrees of superheat.

Measuring Instruments, etc.

We have received from Messrs. Nalder Bros. and Thompson, Limited, 34, Queen-street, Cheapside, E.C., a copy of Section I. of their catalogue, dealing with soft-iron ammeters, voltmeters, etc. A description is included on p. 16 of an automatic accumulator switch, Crawley's patent. This switch is entirely electromagnetic, and it is, therefore, impossible for it to become reversed. It is differential in its action, and switches the cells into the charging circuit as soon as the voltage of the latter has risen sufficiently above the cell voltage, whatever it may be at the time. Moreover, it cuts out the cells directly the charging current falls to zero, there being, consequently, no sparking at the mercury-cups. This device is compact in form.

Galvanometers, etc.

Mr. W. Clark Fisher, Gordon Works, Gordon-road, West Ealing, London, W., has favoured us with advance copies of some pamphlets which he is now issuing descriptive of some of his specialities, these including highest grade improved d'Arsonval galvanometers for scale, zero, or ballistic use, and a "compensating" potentiometer of compact form. The vertical galvanometer bracket, which we illustrate herewith (Fig. 1), was primarily designed for use on board ship to economise space and to prevent any angular motion of the vessel out of the vertical being transmitted to the galvanometer. As shown, it consists of a metal framework slung off a gimbal bearing, and by its own weight thus retaining a vertical position. The framework carries two brackets, to one of which is fitted lamp, reflector, and transparent scale, and to the other a prism and reflector. The galvanometer is supported on a turntable at the back of this second bracket, the prism on which throws the vertical beam from the lantern on to the galvanometer mirror, which, when reflected outwards, is caught on a reflecting strip and by it thrown again in reverse vertical direction on to the reflecting strip on the other bracket, and thence to transparent scale. The design admits of the relative positions of top and bottom bracket with galvanometer being reversed, so that instead of the latter being below test-bench level, and approximately 18in. above floor, it may be placed above the scale—an arrangement which is to be preferred in the majority of cases. The apparatus for land use is rigidly bolted top and bottom to wall brackets, which allow of the same interchangeability of the relative positions of scale and galvanometer, etc. The design also admits of any length scale or scale distance being employed. Full adjustments are fitted throughout, and notwithstanding apparent complication they are easily manipulated, and the proper arrangement effected in a few seconds. The floor space occupied is less than one-ninth the usual 1m. triangle, and for the rest the convenience of a clear test-bench for the placing of any apparatus without regard to obscuration of beam will be readily appreciated by "spot watchers. Fig. 2 illustrates a

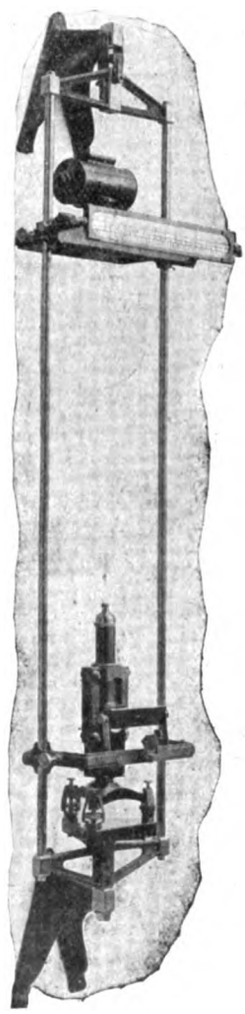

FIG. 1.—Vertical Galvanometer Bracket.

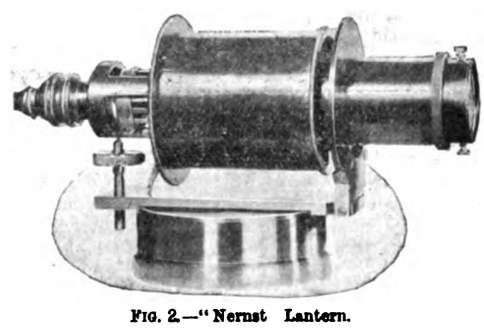

FIG. 2.—"Nernst Lantern.

Clark Fisher "Nernst" lantern for use with galvanometers, etc. This lantern gives a very bright spot with a sharp definition of the dividing line, obtained by a new device, while a variable aperture gives any size spot suitable for bench or lecture work. It has angular, rotation, and vertical movements, being, moreover, cool in use.

Reducing Valves.

From Messrs. W. H. Bailey and Co., Limited, Albion Works, Salford, Manchester, we have a voluminous catalogue of their "Foster's" patent pressure-reducing valves, pump governors, etc. The detailed descriptions and sections given of the various

Digitized by Google

apparatus listed will be found exceedingly useful for reference. An object lesson on erosion, showing the effect of the wire-drawing of steam on valves, is included on p. 17.

Ediswan Accessories.

Catalogue Section 3, just published by the Edison and Swan Company, is claimed to be the most complete list of its kind ever brought before the trade. The contents are set forth in 68 clear and concise pages, everything being standardised, scaled, and, where necessary, accompanied by dimensions. The first part of the list is devoted to electric lighting accessories. Commencing with lampholders, we are taken in succession right back to the main switchboard, it evidently being the company's idea that small things are wanted more frequently than large ones. Amongst novelties we notice the Ediswan improved double-pole switch-holder, for which excellent results are claimed; new designs in high candle-power lampholders; a neat watertight holder; and a dust and damp proof adaptor for lampholders. Cast-iron watertight cases are also listed for ceiling roses and cut-outs. There is an excellent range of wall and floor sockets for all purposes, including some well-designed stage plugs. The "Wedge" tumbler switch naturally comes in for a large share of attention, some six pages being devoted to it. This switch has met with great success owing to its simplicity and efficiency. It is being specified by consulting engineers and architects, and we understand that the makers can hardly turn the switches out fast enough to meet the demand. Amongst new patterns we notice the D.P. tandem type, and several new designs for flush purposes, a watertight pattern, and also a watertight box for the ordinary patterns. The "Safety" tumbler switch comes in for some display; it is specially recommended for use on 500-volt circuits. Amongst the new Ediswan pear switches a two-way pattern is now listed. New designs of chopper and knife switches are standardised in a very large number of switches, finishes, and modifications. A workmanlike series of new regulating switches are shown, and next we come to cut-outs. These are listed in many types, from the circular and oblong china patterns to large new terminal and knife patterns up to 500 amperes. Then come several varieties of automatic cut-outs, and after this the well-known "Edinburgh" and "Economic" fuseboards. The former is now standardised in a size at 50 amperes per way, and both patterns are to be had in many varieties of cases, etc. Distribution boards occupy another six pages, and three distinct types are listed—namely, combinations of "Edinburgh" fuse with "Wedge" or chopper switches, and "Economic" fuses with "Wedge" switches. The last should prove a good selling line, the list price being as low as 5s. per way. Some fine examples of Ediswan main switchboards are illustrated, which show the important and large range of work undertaken by the company. The rest of the catalogue comprises casing, conduit, jointing materials, etc.—*i.e.*, all the ordinary sundries used by wiring contractors.

Polyphase Induction Motors.

Westinghouse polyphase induction motors, types "C" and "C B," for constant speed are fully described in circular B 1,070, just issued by the British Westinghouse Electric and Manufacturing Company, Limited. Illustrations are included of different applications of these motors.

Two-Way Knife Switches.

Messrs. Ernest F. Moy, Limited, Greenland-place, Camden Town, London, N.W., have sent us some sheets dealing with their single-pole, two-way knife switches of standard dimensions. Each switch is fitted with a rapid quick-break action from either position, the main conducting blade carrying a spring-controlled subsidiary blade on each of its edges. Prices are included for switches of from 50 amperes to 1,000 amperes capacity.

United States Metallic Packing.

The United States Metallic Packing Company, Limited, are issuing a revised list of the users of their packings. This list is an exceedingly lengthy one, including, as it does, the names of firms in all branches of industry throughout the United Kingdom, British and foreign vessels, various railway companies, and electric lighting and power stations. Illustrated particulars of the packings are attached.

Catalogue.

The latest sheets of the Electrical Company, Limited, Charing Cross-road, W.C., illustrate and give prices of quick break single-way knife switches, up to 400 amperes 500 volts (E.C. 86); and of carbons for flame lamps, with perpendicular or converging carbons, both cored (E.C. 87).

THE SUPPLY OF ELECTRICITY BILL.

On the resumption of the discussion on the Bill of the Board of Trade for amending the Electric Lighting Acts, Lord Wolverton's Committee of the Lords dealt with Sub-Section 2 of Clause 4 relating to the right of local authorities to purchase electrical undertakings from companies. Under this section of the Bill, as originally framed, a generating station or other works of a company used solely for supplying electricity within the district of a local authority, when situated outside the district, was to be considered as being within the district for the purposes of purchase by the local authorities. Bulk companies were exempted from the clause.

The **Chairman** said the committee were willing to insert the following words in the clause to meet the objections of the companies: "Provided always that any company coming under the operation of this clause may give six months' notice by resolution of the company to the Board of Trade that they will take none of the benefits and incur none of the liabilities."

Mr. Pelham said that the Board of Trade could not agree to those words, and suggested that the following words would meet the views of their lordships and the companies: "Provided that this sub-section shall not, without the consent of the company to which they belong, apply to any generating station, mains, or other works authorised by a special Act before the passing of this Act."

Counsel for the companies urged their lordships to adhere to their own words, but after deliberating in private, the **Chairman** announced that the committee were prepared to accept the wording of the Board of Trade.

Lord R. Cecil, on behalf of the London boroughs, objected to a sub-section in Clause 4 which authorises local authorities to transfer their rights to purchase a private company's undertaking to any other local authority subject to the consent of, and on such terms and conditions as may be approved by, the Board of Trade and with the consent of the company. He submitted that a company had no right whatever to interfere in a matter of that sort.

Mr. Balfour Browne, on behalf of the companies, contended that the suggested amendment would have the effect of putting on to a company a number of different authorities to whom it had never agreed to sell, and that it would involve an alteration in the general law.

Mr. Pelham, assistant secretary to the Board of Trade, also objected to the alteration, and the clause was passed as it stood.

On Clause 5, which permits the exercise of electric lighting powers by local authorities acting jointly with the concurrence of the Local Government Board by means of provisional order, **Mr. Moon**, on behalf of the Metropolitan Electric Company, asked for the insertion of an amendment to the effect that in any area in which a company was authorised to supply for power or lighting purposes the consent of that company be obtained before an order was issued.

Mr. Fitzgerald, representing the Municipal Corporations Association, denied that the principle that local authorities should not combine had ever been laid down.

The committee rejected the amendment.

A proposal by the Municipal Corporations Association to omit Clause 6, which empowers the Board of Trade to grant a provisional order or not at its discretion, was rejected.

An amendment by the Board of Trade was agreed to, directing that the principal provision of the clause shall not apply to any provisional order authorising a company or person to supply electricity so far as the order relates to a district in which the local authority is authorised to supply electricity; and, further, that a provisional order authorising the breaking up of roads outside the area of supply shall not be granted, except with the consent of the local authority, unless the Board of Trade is of opinion that such consent should be dispensed with.

Clause 10 relates to the supply of electricity to premises having a separate supply, and requires the person having such separate supply and who demands a supply from the authorised undertakers to agree to pay such a minimum annual sum as will give a reasonable return on the capital expenditure, and will cover other standing charges incurred to meet possible maximum demands of those premises.

Mr. Coward, on behalf of the London County Council, opposed this clause on the ground that it imposed a new burden on consumers, but it was supported by **Mr. Fitzgerald** and **Mr. Balfour Browne**, and agreed to.

An amendment suggested by **Mr. Fitzgerald** applying the clause to existing contractors was also agreed to, but a new clause giving increased powers to auditors, with an appeal to arbitration, where necessary, proposed by the London County Council, was rejected.

The Bill was ordered to be reported to the House.

APPOINTMENTS VACANT.

Storekeeper, Carlisle Electricity Works. Wages, 25s. per week. Applications by July 25.

Assistant for Meter Department. Salary, 30s. per week. Apply, M E 4, *Electrical Engineer* Office. See advertisement.

Tramways Manager and Engineer, Huddersfield Corporation. Salary, £350 per annum. Applications by noon on Aug. 8. See advertisement.

Clerk of Works, Cheltenham Corporation, to superintend the construction of electric tramways. Salary, £4. 4s. per week. Applications by July 25.

Electrician, Bracebridge, Lincs., to take charge of the boilers, engines, dynamos, and electrical plant at the asylum. Salary, £100 per annum, with house (or equivalent allowance for rent), coal, and light, free of taxes. Application by July 30.

Electrical Engineer, Acton Urban District Council; resident electrical engineer to organise and superintend their electricity undertakings under the direction of the consulting engineer. Salary, £200 per annum, with residence, coal, and light. Applications by July 25.

Digitized by Google

LEGAL INTELLIGENCE.

NORWICH CORPORATION v. NORWICH ELECTRIC TRAMWAYS COMPANY.

Mr. Justice Phillimore delivered his reserved judgment in this action, which was reported in our issue of the 1st inst.

The Corporation claimed £53. 13s. 10d., the cost incurred in repairing and maintaining certain parts of the road adjoining the company's tramways. By Section 57 of the Norwich Electric Tramways Act, 1897, if the company failed to maintain and keep good the junction of the granite setts alongside the lines with the surface of the road, the Corporation, after giving seven days' notice, might do the work and charge the company with the cost, and 5 per cent. interest. This had been done in several parts of the borough. The company denied liability, and submitted that they could not be called upon to repair the setts until the Corporation had made up the road surface to the original level that Parliament contemplated.

The learned Judge held that the defendants were liable, and gave judgment for the Corporation for the amount claimed, plus 5 per cent. interest, and costs.

ELECTRIC TRAMWAYS CONSTRUCTION.

On the application of Mr. Martelli, on Monday, Mr. Justice Kekewich postponed the hearing of the case of the Electric Tramways Construction Company *v.* Pain until after the Long Vacation, in consequence of certain criminal proceedings now pending.

A petition to wind up the company has, as reported in our last issue, been directed by Mr. Justice Buckley to stand over until after the Long Vacation.

ARE ELECTRIC FITTINGS MACHINERY?

An action was heard at the Manchester Assizes last week before Mr. Justice Relf and a jury, in which Thos. Kay, an iron turner, employed by the British Westinghouse Electric and Manufacturing Company, Limited, claimed damages from the company for personal injuries which he received on Feb. 22 last, whilst in their employ.

Mr. Acton, instructed by Messrs. Rowley and Co., appeared for the plaintiff; and Mr. Taylor, K.C., and Mr. Wingate Saul, instructed by Messrs. Norton and Howe, for the defendants.

Mr. Acton said the accident that happened to the plaintiff was due to the neglect of the defendants to fence off certain dangerous parts of machinery. The learned counsel stated that in the usual hurry to go to the "clocking-off" board at the close of work on Feb. 22, the plaintiff was pushed against two copper switch plates, through which a high-voltage current of electricity was running. His face came against the plates, with the result that he was fearfully burned—his right eye, the flesh round it, and the face being burned away. The plates at the time were only 5ft. from the ground and unfenced. The plaintiff had earned 35s. a week, and would be unable to follow his occupation again, as his left eye was in a very bad state through sympathetic disease. The learned counsel asked the jury to say that the existence of the two unprotected plates with the high voltage of current running through them was dangerous. It appeared, said Mr. Acton, that the plates were examined the next day on behalf of the firm, and they were moved from 5ft. above the ground to 7ft. above the ground, they were enclosed in a metal box, and a notice put up warning the men. The defence was contributory negligence, and, secondly, that the defendants were a limited company, and the negligence, if there was any, was that of their manager, who was in the position of a fellow-workman of the plaintiff.

Medical evidence was given as to the extent of the injuries, the doctor stating that the whole of the right side of the plaintiff's face would be so loathsome to look at that he would have to wear a shield or he would not be able to go amongst people. He would suffer a good deal of pain and discomfort throughout his life.

The **Plaintiff** gave corroborative evidence in support of his counsel's statement. In cross-examination, a fellow-workmen, who saw the accident, said the men always rushed the nearest way to join the line for "clocking off." In reply to the jury, another workman said there was no notice put up to direct the men which way to go or not to go. Evidence was also given as to the subsequent alterations to the switch and the notice put up.

Mr. F. Cortez Leigh, electrical engineer, Manchester, said he considered the switchboard to be part of the machinery of the works. He described it as such, because it was absolutely necessary for their works when lighting was required. In reply to Mr. Taylor, witness decidedly maintained that the switch should have been fenced.

Mr. Taylor, K.C., submitted there was no evidence of any breach of duty on the part of the defendants in not fencing a dangerous part of the machinery of the factory. His point was that the actual thing in connection with which the accident happened could not, within the meaning of the consolidated Factory Acts, be described as part of the machinery in a factory. He further maintained that if there had been an omission of duty, it was an omission by a servant of the company.

Mr. Acton submitted that Mr. Taylor's contention was too narrow. He urged that the question whether the switch was part of the machinery was one of fact. He submitted that it was just as much part of the machinery as the gas-engine that drove the dynamo.

His Lordship said he had very great doubt, indeed, whether it could be said to be part of the machinery within the meaning of the Act. The plaintiff had still his common law action for neglect. The question was, was there neglect which involved a want of reasonable care on the part of the directors?

Colonel Montague Craddock, one of the directors, was called for the defence, in order to prove that they had no knowledge of the danger.

Mr. H. S. Loud, general manager, admitted receiving a letter from Mr. Scott Ramen, electrical inspector to the Board of Trade, on June 4, 1903, pointing out that there were a number of power switches, from 3ft. to 5ft. from the ground, entirely unprotected, and saying that it was important that all such switches should be protected by suitable covers. The letter also said that the lighting switches should be treated the same way. He gave instructions that the work should be done without consulting the directors. In October, 1903, there was another letter about the switches from the Board of Trade.

His Lordship pointed out that from June to October witness allowed that dangerous switch to remain in that condition, and asked Mr. Loud what was the good of giving orders if he did not see them carried out. Attention was again called in October, and it was still unprotected in February.

Mr. Taylor, K.C., urged that the whole question was whether or not it was the responsibility of the directors or of a fellow-servant. His case was that a fellow-servant was responsible, and therefore the directors were not liable for any damage. Further, plaintiff knew the switch was dangerous, and behaved negligently.

Mr. Acton said his Lordship had held that the question whether the switch was part of the machinery within the meaning of the consolidated Factory Acts was a question of law. It was evident from the letters produced by the defence that the factory inspectors considered it their duty to inspect these appliances. Apart from that he saw no merit in the defence. He quoted the dictum of Lord Herschell that the employers' duty was to provide proper appliances, to maintain them in proper condition, and to so carry on their operations as not to subject their employés to unnecessary risk.

His Lordship having reviewed all the circumstances at length, the jury returned a verdict in favour of the plaintiff, awarding damages to the amount of £850.

COMPANIES' MEETINGS AND REPORTS

ELECTRIC CONSTRUCTION.

The eleventh annual meeting of shareholders in this Company was held on the 14th inst. at Winchester House, Mr. James William Barclay presiding. The report was published in our issue of the 8th inst.

In the course of his remarks, the **Chairman** observed that the orders on hand included, amongst others, important contracts with the London County Council and with the Great Western Railway Company for their new electrical installation at Park Royal. Within the last few years new factories had been established both in England and in Scotland, and the Chairman stated that, although he looked for a development in the use of electric power, the Company must expect, and be prepared for, keen competition for some time. The Company were well equipped for the struggle. The works were up to date, and no expense had been spared in adopting labour-saving machinery, and the directors had full confidence in the skill of the Company's engineers and in the zeal and ability of the employés.

The report was adopted *nem. con.*

METROPOLITAN ELECTRIC SUPPLY.

An extraordinary meeting of the Metropolitan Electric Supply Company, Limited, was held on Tuesday at Winchester House, Mr. W. H. Cripps presiding.

The **Chairman**, in moving the adoption of a resolution to divide the profit on the sale of the St. Marylebone portion of the undertaking by a £6 per share bonus on the ordinary shares, stated that there was a sum of £1,212,000 to be dealt with as a result of the sale to the Borough Council, of which £700 000 was regarded as profit. The bonus would absorb £600 000, and a part of the remaining £100,000 would go to reserve, so that at the end of the year that fund would stand at £230,000, all in gilt-edged securities. They took £500,000 to represent capital, and the suggestion was to reduce capital from £1,000,000 to £750,000 by giving every holder of two £10 shares three £5 shares and £5 in cash. That, however, was a scheme for subsequent consideration, and would have to be carried through by Act of Parliament. Having referred to the fine site received as part of the Sardinia-street station award, he said the Board were advised by eminent counsel that they could treat the £600,000 already mentioned as profit, but the debenture holders declared it ought to be treated as capital and not as dividend. They had as security for their £250,000 the whole of the concern and the £500,000 now lying in the bank; but they were not satisfied, and were going to the Court of Chancery for an injunction to prevent the distribution of the £6 a share bonus. He thought that was the best thing they could do, and the matter would come on for consideration in about 10 days. If, however, the shareholders now passed the resolution, he promised that as soon as the Court gave authority the same day cheques should be sent out. As to the current year's business, it promised to be very good, but the Board thought it would be wise not to pay more than 9 per cent.; next year, with the reduced capital, they would again pay 9 per cent., and in the two following years the same, aided by the margins carried over, and after that they believed the ordinary growth of business would enable them to distribute dividends on an ascending scale.

Sir Eyre Shaw seconded the motion, which was agreed to unanimously.

CITY OF BUENOS AYRES TRAMWAY.

An extraordinary general meeting of the City of Buenos Ayres Tramway Company, Limited, was held at Winchester House on Monday

Digitized by Google

for the purpose of considering resolutions dealing with the proposed sale of the undertaking, assets, and property of the Company to the Anglo-Argentine Tramways Company, Limited.

Mr. J. Heaton presided, and explained that the Anglo-Argentine Tramways Company had made a definite offer (of which we gave particulars in our issue of the 8th inst.) to take over and work the line. That company had further agreed to secure to this Company a sum of £68,960 per annum as a preferential revenue charge upon the united undertakings for a period of 80 years, an annual sum for necessary administration, and a further sum for compensation for those deprived of office. The £68,960 was equal to a dividend of 8 per cent. per annum on the present share capital, together with interest at 6 per cent. per annum upon the debenture stock. There would be surplus lands which the Anglo-Argentine Company would not require, and which would be handed back. The value of these lands was estimated at a considerable sum, which, when realised, would be available for distribution.

The resolutions were unanimously adopted.

ANGLO-ARGENTINE TRAMWAYS.

At an extraordinary general meeting of the Company at Winchester House on Monday, the shareholders ratified the agreement for the purchase of the business of the City of Buenos Ayres Tramways Company, and authorised the directors to increase the capital of the Company in due course by the sum of £600,000, by the creation of 120,000 new ordinary shares of £5 each, "and to issue such shares, or any of them, subject to such conditions as to postponement of rights to dividend and otherwise as they may think fit."

A resolution was also passed altering the articles of association.

GENERAL ELECTRIC.

The report of the directors to be submitted at the ordinary general meeting of the shareholders to be held on Wednesday, July 27, states that the net trading profits and income from investments, etc., for the past year amounted to £83,864. 14s. 1d., and that after deducting depreciation and debenture interest amounting to £25,607. 14s. 11d., there remained a balance of £58,256. 19s. 2d., out of which a dividend on the preference shares at the rate of 5 per cent. for the year ended March 31, 1904 had been paid, absorbing £12,500, leaving an available balance of £45,756. 19s. 2d., which the directors recommend should be appropriated as follows: to payment of managing directors' and employés' bonus, £4,575. 14s.; to payment of dividend on ordinary shares at the rate of 7 per cent. for the year ended March 31, 1904, £21,126; to reserve account, £20,055. 5s. 2d. The reserve account stands in the accounts at £60,210. 2s., being the amount of undivided profits as at March 31, 1903. The proposed appropriation of the undivided profit of the year ended March 31, 1904, amounts to £20,055. 5s. 2d., giving a total of reserve account of £80,265. 7s. 2d. The directors remark that the trading profit must be deemed satisfactory considering the general depression of trade. The Witton engineering works and foundry are now in full working order. The favourable anticipations expressed in last year's report have been realised, and the number as well as the nature of the contracts in hand are very encouraging for the future. The position of the carbon works is much improved. The Manchester and Birmingham factories continue to show good results.

DIRECT UNITED STATES CABLE.

The report for the six months ended June 30 states that the net revenue amounted to £43,121, as compared with £48 886 for the corresponding period of 1903. The working and other expenses, including income tax, amounted to £21,185, leaving a balance of £21,936 as the net profit, making, with £2,479 brought forward and £1,966 compensation for surrender of leases of premises at New York, a total of £26,381. For the corresponding period of 1903 the working expenses and other payments amounted to £21,724. Three quarterly interim dividends of 3s. each per share, amounting to £27,319, have been declared and paid during the year, and a final dividend of 3s. per share is now proposed, making, with the three interim dividends, 3 per cent. for the year, being a total distribution of £36,426. After transferring £6,000 to the reserve fund account, the balance of £2,168 is carried forward. The reserve fund account has been debited with £11,725 for cost of cable repairs, and, after being credited with interest on the investments and amount transferred from revenue, the balance now amounts to £463,952, taking the investments at cost price.

EASTERN TELEGRAPH.

The report for the half-year to March 31 last shows a total income of £635,885, as against £626 800 for the corresponding period. Expenditure, however, has likewise advanced, and the increase in net revenue is only £2,000, the total being £419,965, which, with the carry forward from the preceding half-year of £32,867, brings the available balance up to £452,833. After making provision for income tax, interest on loan from a sister company, and debenture and preference interest, there remains £359,233. A sum of £178,000 is placed to the reserve funds—£7,000 less than last year—while the dividend on the ordinary stock with bonus is maintained at the same rate, 7 per cent. per annum.

CITY AND SOUTH LONDON RAILWAY.

The report states that the receipts for the past half-year amount to £80,203, and the cost of working has been £36,569, leaving a profit of £43,634. Inclusive of the balance brought forward from Dec. 31 last, the net revenue account shows an aggregate total of £44,403. After making provision for the debenture stock interest and the transfer to the renewal fund of £1,500, a balance remains available for dividend of £31,684 Out of this sum the directors recommend that the full dividend of 5 per cent. per annum be paid on the preference stocks, and that a dividend at the rate of 2¼ per cent. per annum be paid upon the consolidated ordinary stock for the half-year, leaving a balance of £701 to be carried forward to the next account. This represents a slight decrease in the dividend as compared with last year, the competition from the electric trams having increased owing to the progress of the reconstruction operations. Negotiations with the railway companies and other public bodies with whom agreements have to be made in respect of the extensions to King's Cross, St. Pancras, and Euston have made considerable progress, but are not yet sufficiently advanced to allow a contract to be entered into for the construction of the line. It is, however, hoped that these negotiations will be brought to a conclusion at an early date, and authority will therefore be asked for the creation and issue, when required, of the capital necessary to carry out the extension, the interest on which will not be a charge on the revenue of the Company until the line is open for traffic. The works of the Baker-street and Waterloo Railway are making rapid progress, and the plans of the low-level subway at the Elephant and Castle, connecting the platforms of the two stations, have been agreed. The Great Northern and City Railway was opened in February last, and the interchange traffic with that railway is steadily progressing.

NEW COMPANIES REGISTERED.

Paddington Electric Supply Company, Limited.—Capital £1,000. Objects: to carry on the business of electrical, mechanical, and chemical engineers, electricians, etc. Registered office: 19, Carnaby-street, Golden-square, W.

Murdock Gas Fittings Company, Limited.—Capital, £5,000. Objects: to acquire and carry on the business of C. Lucas at Bridge-street West, Birmingham, as the Murdock Gas Fittings Company, formerly a branch of the business of Chris. Lucas, Limited, as lamp manufacturers and dealers in electric, gas, and sanitary fittings, brass-founders, etc.

Taylor's Patent Shunting Lever, Limited.—Capital, £200,000. Objects: to acquire any inventions relating to railways or tramways; to acquire from D. E. Cardinall, of 28, Cromwell-road, Hove, Sussex, the benefit of certain existing inventions relating to improvements in means or appliances for operating points and signals for railways and tramways, and for other like purposes, etc.

R. H. Longbotham and Co., Limited.—Capital, £10,000. Objects: to acquire the business carried on by R. H. Longbotham, at Ings Foundry, Wakefield, and at Newcastle-on-Tyne, as R. H. Longbotham and Co.; to manufacture and deal in machinery, apparatus of all kinds, and to carry on the business of electrical and general engineers, distributors and suppliers of electricity, etc. Registered office: Ings Foundry.

Barber and Colman, Limited.—Capital, £10,000. Objects: to acquire for the purpose of sale in the United Kingdom, the British Colonies, Europe, and Asia mechanical contrivances, patented articles, appliances, devices, and goods manufactured, patented, and supplied by Messrs. Barber and Colman, of Rockford, Illinois; by the International Battery Company, of Chicago; by the Krag Metallic Company, of Chicago; and by the Woodward Governor Company, of Rockford, Illinois, etc. Registered office: 25, South-corridor, Royal Exchange, Manchester.

Liens Registered.

Wexford Engineering Company, Limited, Wexford.—Lien registered July 2 for £1,000, part of £6,000; amount previously issued, £5,000; charged on the undertaking and all the property, including the uncalled capital.

British Electric Calibrated Fuse Company, Limited.—£100 debentures, part of a series created Dec. 4, 1903, to secure £3,000, charged on the company's undertaking and property, present and future, including uncalled capital. Holder: J. Lang, 137, Fenchurch-street, E.C. No trustees. Total amount previously issued of same series, £1,650.

Isle of Thanet Electric Tramways and Lighting Company, Limited, London, E.C.—Trust deed registered July 8 for securing £50,000 debenture stock, supplemental to trust deeds dated Jan. 18, 1902, and Aug. 5, 1902. Trustee: City Safe Deposit and Agency Company, Limited; charged on the undertaking and all the properey, present and future.

Otto Electrical Manufacturing Company, Limited (Manchester).—Issue on June 23 of £1 500 debentures, part of a series created June 22, 1904, to secure £5,000, charged on the company's undertaking and property, present and future, including uncalled capital. Holder: J. Deakin, The Hall, Wormhill, near Buxton, Derbyshire. No trustees. No previous issue of same series.

New General Traction Company, Limited.—A trust deed, dated June 22, 1904, to secure £80,000 prior lien debentures, has been registered. Property charged: shares in the Norwich Electric Tramways, Coventry Electric Tramways, and Douglas Southern Electric Tramways, bonds of the Philadelphia, Morton and Swarthmore Street Railway Company, Limited, and the Media, Middleton, Aston, and Chester Electric Railway Company, and the company's other assets, present and future, ranking in priority to a trust deed dated June 28, 1901, securing £200,000 debentures, and certain agreements. Trustees: Trustees', Executors', and Securities' Insurance Corporation, Limited, Winchester House, E.C.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Cardiff.—Tenders are invited for two road motor-wagons for the Health Department. Tenders by July 25.

Worksop.—Tenders are to be obtained for cables, etc., for mains, and additional feeder, estimated at £1,000.

Fulham.—Tenders are required for two steam water-tube boilers, steel flues, etc. Tenders by July 27. See advertisement.

Salford.—The Corporation invite tenders for the wiring of the Pendleton Town Hall. Specifications, etc., may be obtained from the Borough Electrical Engineer, Frederick-road Works, Pendleton. Tenders by July 23.

Bromley.—The Council invite tenders for the provision of a 15-kw. electric light installation at the refuse destructor works. Specifications, etc., may be obtained at the office of the Borough Engineer. Tenders by 3 p.m. on July 26.

Glasgow.—The Trustees of the Clyde Navigation invite tenders for two electric 32-ton coaling hoists for Clydebank Dock. Specification, etc., may be obtained from Mr. Geo. H. Baxter, 16, Robertson-street, Glasgow. Tenders by noon on July 25.

Swansea.—Tenders are invited for the supply of sundry fittings for an installation of electric light at the Swansea Working-Men's Club and Institute, Alexandra-road, Swansea. Specification can be obtained from the Steward. Tenders by July 25.

Hackney.—The Guardians invite tenders for fitting up a system of electric fire-alarm bells at their Homerton establishments. Specification, etc., can be obtained from Mr. Frank R. Coles, Clerk's Offices, Sidney-road, Homerton, N.E. Tenders by 2 p.m. on July 27.

Wimbledon.—The Urban District Council invite tenders for extensions to the present refuse destructors at their electricity works. Particulars may be obtained from the Engineer and Surveyor to the Council, Council Offices, Wimbledon. Tenders by 10 a.m. on 25th inst.

Newcastle-upon-Tyne.—The Guardians invite tenders for the installation of the electric light in the hospital block at the workhouse. Specifications may be seen at the offices of Messrs. Newcombe and Newcombe, 89, Pilgrim-street, Newcastle-upon-Tyne. Tenders by 12 noon on Aug. 4.

Plymouth.—The Corporation invite tenders for (25) steam alterrator, etc; (26) Lancashire boilers, with mechanical stokers; steam, exhaust, and other piping; ejector, condenser, valves, etc. Specifications, etc., may be obtained from the Borough Electrical Engineer. Tenders by Aug. 15.

Portsmouth.—Tenders are invited for the supply of 13,000 to 15,00 tons of best Durham rough small and best north country screened nut coal, between Aug. 1, 1904, and Aug. 1, 1905, for the electricity station. Particulars may be obtained from the Town Clerk. Tenders by 10 a.m. on July 26.

Aston Manor.—The Corporation invite tenders for the supply, delivery, and erection complete of pipework, etc. Specifications, etc., may be obtained from Mr. T. J. Ballard, Electricity Works, Chester-street, Aston Manor. Tenders before 12 noon on July 28. See advertisement in former issue.

Hapton (Lancs.).—Tenders are invited for the street-lighting of the parish of Hapton for eight months, commencing Sept. 1 and ending April 30, 1905; also tenders for same period during years 1905, 1906, and 1907. Tenders to Mr. Ed. O'Shaughnessy, clerk to the Hapton Parish Council, 16, Hammond-terrace, Padiham, by July 30.

Dover.—The Corporation invite tenders for the supply and erection of one surface-condenser air-pump, two centrifugal pumps, and pipework, to heat 10,000lb. of steam per hour and to give a vacuum of not less than 28in. Specifications, etc., may be obtained on application to Mr. L. W. Woodman, borough electrical engineer, Park-street, Dover. Tenders by July 30.

Beverley.—The Visiting Committee invite tenders for various work in connection with the provision of new fire appliances at the asylum, including internal electric fire-alarm communications. Specifications, etc., may be obtained on and after 25th inst. at the office of Messrs. Maxted, Knott, and Coles, engineers, Burnett-avenue, High-street, Hull. Tenders by 12 noon on Aug. 10.

Islington.—The Lighting Committee invite tenders for the following: (1) supply of a 25-b.h.p. single-phase 50-period 200-volt alternating-current motor, with all starting gear, etc., complete; (2) supply of three sets of tail-rods and bearings for 1,000-b.h.p. engines. Specifications, etc., may be obtained upon application to the Electrical Engineer, 50, Eden-grove, Holloway. Tenders by 12 noon on July 27.

Chorlton-cum-Hardy (Lancs.).—The Withington Urban District Council invite tenders for the supply and erection complete of one 20in. centrifugal pump and electric motor and one 20in. centrifugal pump and oil-engine at their Chorlton sewage works. Specifications, etc., may be obtained on application to Mr. A. H. Mountain, A.M.I.C.E., Town Hall, West Didsbury, near Manchester. Tenders by July 29.

Perth.—The Corporation invite tenders for the construction and equipment of about 4½ miles of route length of tramways, constructed as single line with passing places—viz.: (1) permanent way and paving, including copper bonding; (2) overhead equipment; (3) cables, ducts, etc.; (4) cars and equipments; (5) car depôt building. Specifications, etc., can be obtained from the Town Clerk. Tenders before noon on Aug. 16.

Greenwich.—The London County Council invite tenders for the manufacture, delivery, and erection at the tramways electricity generating station at Greenwich of the following plant: two 24in. centrifugal pumps and motors, one 3in. centrifugal pump and motor, two n. by 8in. three-throw air-pumps and motors, one 3in. artesian well pump, fixed and rotary strainers, etc. Specifications, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 4.

Australian Commonwealth.—Tenders will be received at the office of the Deputy Postmaster-General, Hobart (Tasmania), until noon on Sept. 30, 1904, for the supply and delivery at the General Post Office, Hobart, of one multiple metallic branching switchboard. Specifications may be seen at, and tender forms and conditions obtained from, the General Post Offices at Hobart, Melbourne, Sydney, Adelaide, Brisbane, and Perth. Tenders should be endorsed "Tender for Switchboard," and addressed to the Deputy Postmaster-General, Hobart. Tenders may be deposited in the tender-box at the General Post Office, Hobart, or, if sent by post, must be prepaid and registered. Tenderers must state the name of the country in which the switchboard will be manufactured.

Berga, etc. (Spain).—The *Gaceta de Madrid* for June 26 publishes a Royal decree calling for tenders for the installation and working of a telephone system and central stations at Berga and sub-stations at Gironalla, Puigreig, Balsareny, Sallent, Castelladral y Cardona. Tenders will be received within 30 days' date of publication at the office of the Dirección-General of Posts and Telegraphs, 10, Calle de Carretas, and at the office of the Civil Governor, Barcelona, a provisional deposit of 2,000 pesetas (or about £57) being required from persons tendering. The maximum period for the concession is for 20 years, and the adjudication of tenders will turn on the reduction of this period. The *Gacetas* may be seen on application at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, E.C., any day between 10 a.m. and 5 p.m. (Saturdays 10 a.m. to 1 p.m).

Reichenberg (Austria Hungary).—The project for the establishment of a central distributing electric power and light plant in the Reichenberg land district has taken definite form. The territory included is about 10 miles square, and 24 towns and villages have joined in the movement and subscribed to the capital stock. Some 10 more are expected to join. The population of the district, exclusive of Reichenberg, is about 60,000. Stock is subscribed at present to the amount of £40,000, and this it is proposed to increase to £80,000. The principal purpose of the corporation will be the distribution of electric light and power, with the possibility of installing and working a system of suburban electric tramways. Tramway and light franchises for the city of Reichenberg are at present owned by private corporations, and at their expiration it has been generally supposed that the city would take over and conduct the enterprises. Negotiations are pending, however, which may change the situation in this respect. Communications regarding equipment, etc., may be addressed to directors Alfred Ginskey, Maffersdorf, and Dr. Richard Pirkl, Reichenberg.

RESULTS OF TENDERS.

Bridge (near Canterbury).—The tender of L. Sunderland and Co., Westminster, has been accepted for electric light installation at Bridge-hill House.

Northallerton.—The Urban District Council have accepted the tender of the Northallerton Electric Lighting Company for lighting the town for two years.

Loughborough (Leicestershire).—The Town Council have accepted the following tenders: E. Green and Son, Limited, economiser, £402. 10s.; T. Sugden, Limited, superheaters (2), £142. 10s. each.

Brighton.—The tender of Siemens Bros. and Co., Westminster, at £39,420, has been accepted for the supply and laying of three-core high-tension and other cables from the Southwick works to the North-road sub-station.

Renfrew.—The Town Council have accepted the following tenders: J. and R. Houston, Greenock, purifiers; R. Laidlaw and Son, Glasgow, exhausters; C. M. and J. Hamilton, Hamilton, retort bench; Barrowfield Ironworks, Glasgow, retort bench ironwork; Penman and Co., boiler; Clapham Bros., Limited, Keighley, condensers.

St. Pancras.—The Borough Council have accepted the tender of W. F. Dennis and Co. for the supply of cables at £800. 15s. 6d., an amendment that the next lowest tender—that of Callender's Cable and Construction Company at £885. 11s. 10d.—be substituted on the ground that where possible the Council should take British instead of foreign work, having been lost by a narrow majority.

Air Compressors, etc.—R. W. Blackwell and Co., 59, City-road, E.C., report an order from the Underground Electric Railways Company of London for over 200 50-cubic feet motor-driven compressors for the air brakes on the new trains which are to be operated on the Metropolitan District Railway; they are also supplying the company's electric locomotives with their combined vacuum pumps and air compressors.

Rochdale (Lancs.).—The Corporation have received the following tenders for the supply, delivery, and laying in the borough high and low tension feeder cables, etc.: British Insulated and Helsby's Cables, Limited; W. T. Henley's Telegraph Works; Callenders, Limited; W. T. Glover and Co., Limited, Trafford Park, Manchester (accepted); St. Helens Cable Company, Limited; Western Electric Company.

Swansea.—Sixteen tenders have been received for tramway switchboards at Strand and destructor works generating stations. The lowest for specified instruments were Ferranti Limited—specified instruments £904, alternative instruments £801. The Council have decided to let Mr. Prusmann select the tender of Messrs. Dorman and Smith (£1,027 specified instruments) or British Westinghouse Company (£1,033. 2s. 6d. specified, £1,018 9s. 6d. alternative).

Bursiem.—The Corporation have accepted the following tenders for the supply, delivery, and erection of the following plant, etc.: (A) water tube boilers; (B) steam-piping, pumps, water-softener, etc.; (C) engines

Digitized by Google

(D) dynamos, balancer, and boosters; (E) switchboard; (F) cables, including laying; (G) arc lamps; (H) accumulators; (I) refuse destructor plant: Babcock and Wilcox, boilers, £1,087; Sir Hiram Maxim, piping, £1,009; Dick, Kerr, and Co., engines and dynamos (with Howden engines), £1,863; General Electric Company, balancer booster, £337; Crompton and Co., switchboard, £598; Callender and Co., cables, £9,554. 1s. 8d.; Crompton and Co., arc lamps, £443; E.P.S. Company, accumulators, £780. 5s.; Heenan and Froude, destructor, £3,095.

West Ham.—The Education Committee have received the following tenders for the electric wiring and fittings for an installation of electric light at the West Ham Park Elementary Schools, Stratford, E.:

Noble and Co.	£960	10	0
Tamplin and Makovski	769	10	0

BUSINESS NOTES.

TRACTION.

Rawmarsh.—The negotiations with the company are still hanging fire.

Darwen.—The tramways account to March 31 shows a loss of £2,949.

Belfast.—The Corporation's Bill has been read a second time in the Commons.

Luton.—The Town Council have decided to include a route along Dunstable-road in the tramways scheme.

Sweden's Railways.—It is reported that the electrification of the State Railways in Sweden is under consideration.

Colchester.—The Board of Trade inspection of the Colchester tramways is fixed for Tuesday next, the 26th inst.

Darlington.—Saturday was a record day for the new cars, over 13,000 passengers being carried, the receipts exceeding £54.

Prestwich.—The District Council have obtained a definite promise from the Salford Corporation that work on the track from Heaton Park will be commenced shortly.

Newport (Mon.).—With a view of inducing greater carefulness and smartness in looking out for passengers, the Electricity Committee have adopted a system of bonuses for drivers and conductors.

Manchester.—Saturday was a record day on the Corporation tramways. More passengers were carried and more money was received in fares than on any one day since the municipalisation of the system. The earnings were close upon £3,000.

Morecambe.—At a meeting of the Town Council the Tramways Committee reported that negotiations were still proceeding with the local tramway company with reference to the proposed electrification of the trams, and certain proposals were before the directors.

Maidstone.—The Board of Trade inspection and opening of the tramways took place last week, everything passing off satisfactorily. The total cost amounts to £23,000. Half-a-dozen double-deck cars will be in use at first. The authorised speed is nine miles an hour.

Dublin and Lucan Electric Railway Co.—For half-year ended June 30, 1904, the directors propose a dividend of 10 per cent. on the preference shares (reducing the arrears to nine months), placing £100 to reserve account, and carrying forward a balance of £161 to next half-year.

Northampton.—The official opening of the new electric tramways took place yesterday afternoon, the Mayoress starting the first car from Mercer's-row, another following shortly afterwards. The cars proceed to Kingsley, on to St. James's End, and thence to Abington, the guests being subsequently entertained at a garden party.

Sheffield.—At last week's meeting of the Corporation a scheme was foreshadowed for establishing a service of motor omnibuses to run from various termini to populus districts and villages beyond at the cheapest rates. The traffic would not be sufficient to justify the laying down of tramlines, but the running of motor 'buses would pay.

Nelson.—It is reported that numerous complaints are being made at the unsatisfactory nature of the tramways connection at the Colne boundary, passengers from the Nelson district having been put to much inconvenience through the inability of the Colne Tramways Company to meet the Nelson cars as they have arrived at the boundary.

Bettws-y-coed.—The Carnarvonshire County Council have approved the draft order, plans, etc., of the Penmachno, Corwen, and Bettws-y-coed light railway, subject to certain modification, including the insertion of a clause for the avoidance of injury to natural scenery, and changes in the places at which the railway should cross the main road.

Liverpool.—The receipts of the Corporation tramways for the fortnight ended July 9 were £22,542. 7s. 5d., as against £21,722. 17s. 10d. last year, an increase of £819. 9s. 7d. The passengers numbered 4,845,682, compared with 4,660,065 last year, an increase of 185,617, and the mileage travelled by 381 cars, as against 407, showed an increase of 12,289.

Leeds.—The Corporation have come to an agreement with the Wakefield and District Light Railways Company for the through running of trams between Leeds and Wakefield and Leeds and Rothwell. By August next it will be possible to travel by tram from Leeds Corn Exchange to Wakefield, a distance of about 10 miles, for the sum of 6d., which is 3d. cheaper than the present railway fare.

Falkirk.—The Town Council have forwarded the draft conditions as to the running of the electric cars on Sundays to the promoters, the Falkirk and District Tramway Company. The Council reserve to themselves the right to purchase the undertaking from the company on a six days' running basis, and to prohibit the running of the cars during the hours of public worship. They also stipulate that the tramway employés shall be engaged only six days per week.

Central London Railway.—The directors of the Central London Railway Company have declared a dividend for the half-year ended June 30 at the rate of 4 per cent. per annum on the undivided ordinary and preferred ordinary stocks, and a dividend at the same rate on the deferred ordinary stock, provided for and payable at the end of the year's working. The balance to be carried forward is £48,737, in which is included £37,000 from the previous half-year.

City and South London Railway.—The accounts for the half-year ended June 30 show a balance, after providing for debenture stock interest, dividend on the preference stocks, and transferring to renewal fund £1,500, sufficient to allow of a dividend on the consolidated ordinary stock for the half-year at the rate of 2½ per cent. per annum, carrying forward £701. The dividend for the corresponding period last year was at the rate of 2¾ per cent. per annum, carrying forward £1,500.

Electric Railway Lock.—An automatic safety lock for railway carriage doors has just been put upon the market. All the doors of a train fitted with the lock fasten automatically immediately the train starts and unlock automatically when the train comes to a standstill. By the movement of the train a current of electricity is generated, and this is centred on a powerful magnet which draws a bolt into a slot, thus securing the door. When the train stops the current ceases, the bolt drops, and the door is released.

Bath.—Last week Colonel von Donop, representing the Board of Trade, expressed approval of the working and the construction of the new line which has been laid down from High-street, round the Orange-grove, Terrace-walk, and North-parade, and down Pierrepont and Manvers streets to the Great Western Railway Station. The car travelled along the metals smoothly, and all the corners were easily negotiated. The inspector then proceeded in a car to Combe Down to examine the progress of the work in connecting up the track with Combe Down.

Pontypridd.—At the meeting of the Pontypridd District Council Electricity and Tramways Committee a report was read of the negotiations between Mr. Hugh Bramwell, who had been deputed to meet the British Electric Traction Company with a view to the purchase of that company's horse tramways from Pontypridd to Hafod. The company wanted £6,000, and Mr. Bramwell offered £5,000 on behalf of the Council. As there seemed to be no chance of a settlement, it was resolved to refer the matter to the arbitrator appointed by the Board of Trade, Sir C. S. Moncrieff.

Compensation Limit.—The proceedings against Mr. A. Muir Wilson, a member of the Sheffield Corporation, for refusing to accept, and consequently being unable to produce, a ticket came before the Sheffield Stipendiary last week, Mr Wilson's reason for the refusal being that the notice on the back of the ticket sought to limit liability for accidents to £25. The facts were not in dispute, the question being whether the action of the Corporation was *ultra vires*. Ultimately a nominal fine of 1s. was imposed, it being understood that Mr. Wilson intended taking the case to a higher tribunal.

Electric Standards in Roads.—The Assistant Secretary of the Railway Department of the Board of Trade received on Monday a deputation from the Roads Improvement Association, who brought to his notice a number of questions, including the erection of standards in the centre of the carriageway for tramway and light railway purposes. The deputation urged that the standards were unnecessary and dangerous, and pointed to the narrow margin on either side of the tramways. Sir Herbert, in reply, said the representations should receive the careful attention of his department.

Suggested Light Railway.—The report of the Joint Committee of the Gloucestershire and Worcestershire County Councils on the proposed Gloucester to Malvern light railway, which had already been considered by the latter Council, as reported in our issue of the 17th ult., was presented at the last meeting of the Gloucestershire County Council. The committee were unable to recommend that the circumstances would justify the necessary outlay. A suggestion was made that motorcars might be run, and that the Great Western Railway

Digitized by Google

should be approached. Ultimately the subject dropped without any action being taken.

Swansea.—The contractors, Messrs. Dick, Kerr, and Co., have completed a section of the tramways, extending to some 3¼ miles, and representing about a third of the system. A communication has been received from the tramway company in respect to the short strip of track beyond the borough boundary. The company state that they are not prepared to run any risk, but would run over this strip at per car mile, they to hand over all the receipts of this section. The company also asked for the payment of £6,640. 10s., agreed upon in connection with the overhead electrical equipment, Neath-road. It was decided to defer compliance with the request for the present, as it was considered that if the amount was paid before a lease has been entered into complications might arise.

Southport.—The year's returns of the Corporation trams show a deficit of £341, against £1,223 last year. The traffic receipts totalled £17,304, against £16,179, and the operating costs were reduced from £11,232 to £10,986, showing a gross profit of £6,660; but interest on loans and lease rentals absorbed £3,803, and sinking fund £3,198. The following is an analysis of the working for the years 1903-4 and 1902-3 respectively: length in miles, 10·77 (10·77); car miles run, 431,019 (418,324); passengers carried, 3,837,208 (3,535,434); passengers per car mile, 8·90 (8·45); traffic revenue per car mile, 9·63d. (9·28d.); operating costs per car mile, 6·12d. (6·44d.); traffic revenue per passenger, 1·08d. (1·10d.); operating costs per passenger, 69d. (·76d.); Board of Trade units used, 492,261 (458,472); population of district, 49,000 (49,000); number of times population carried 78 (72).

Metropolitan Electric Tramways Co.—On Tuesday last Major J. W. Pringle, R.E., and Mr. A. P. Trotter made an official inspection, on behalf of the Board of Trade, of the tramways from Finsbury Park to Wood Green and Seven Sisters Corner, Tottenham, reconstructed for electric traction on the overhead system by the Metropolitan Electric Tramways, Limited. Satisfaction was expressed regarding the manner in which the work had been carried out, and these important sections will therefore be opened for public traffic immediately on the receipt of the Board of Trade certicate. They form the first part of an extensive system, with a total length of about 50 miles of electric tramways and light railways in North London. We understand that the first result of the change from horse to electric traction will be a reduction from 1½d. to 1d. in the fare from Finsbury Park to Wood Green terminus.

Cambridge.—At a special meeting of the Town Council the Law and Property Committee reported that they had had two interviews with Mr. A. A. C. Swinton, M.I.C.E., on behalf of the Cambridge Electric Tramways Syndicate, with reference to the electrification and extension of the borough tramways, and the negotiations had now reached a point when it was desirable to consider the question of routes. As in this matter the interests of the Corporation and the syndicate were equally concerned, Mr. Swinton suggested that if the Corporation would employ an expert to advise them on this question, the syndicate would be prepared on their part to pay the cost of obtaining such expert opinion. Under those circumstances the committee recommended that Messrs. Kincaid, Waller, and Manville, of Westminster, who were employed by the Corporation in 1899, be asked to advise as to the various routes which should be adopted in the event of the electrification of the tramways being carried out. The report was adopted.

"Live Rail" Dangers.—In the course of an interview with a representative of the *Manchester Guardian*, Dr. J. A. Fleming expressed the view that there could be no adequate protection for "live rail" dangers except by covering the line. He remarked that on the Metropolitan District Railway a board was being bolted alongside the rail, the top edge of it being slightly higher than the surface of the metal. Dr. Fleming, however, considered this insufficient, and suggested a device by which the "live" rail would be covered with a wooden shelter arrangement the section of which would resemble a figure 7 or a capital L inverted. The picking-up bar of the motor would then have to be bent so as to pass under the hood of the shelter. Neither the bending of the bar nor the erection of the board arrangement, remarked Dr. Fleming, presents any difficulty, nor would the latter be very costly. "Some such protection," he continued, "would obviate the perils now attending the 'live' rail, for then neither men nor cattle could get against the metal by accident. If a man fell over it he would touch only the harmless wood. Some such protection will, I am sure, soon have to be recognised as a compulsory necessity."

Llandudno and Colwyn Bay Electric Tramway.—At the Colwyn Bay Hotel, last week, Colonel Von Donop, on behalf of the Board of Trade, held an enquiry with reference to the application of the Llandudno and Colwyn Bay Electric Railway Company for an extension till this time next year of the order authorising the construction of the light railway. It was stated on behalf of the promoters that the delay had been owing to various difficulties which the syndicate had to contend with. A contract had now been entered into for the execution of the work, and another contract had been entered into with the Tramways Construction Company, under which the capital required, £40,000, would be supplied. The agreements referred to were produced, and copies of them handed to the inspector. Mr. Leslie, of Liverpool, who appeared for the Tramways Construction Company, confirmed the statement as the capital being forthcoming, and in reply to a question said none of the money his clients would advance was in respect of the expenditure already incurred in the obtaining of the order, etc, which is said to have been about £20,000. At the close of the enquiry the inspector visited those portions of the light railway which had been completed or partially completed between Rhos-on-Sea and the Llandudno boundary.

Tees-side.—The Middlesbrough, Stockton, and Thornaby Electric Tramways Bill, promoted by the Imperial Tramways Company, was before the Select Committee of the House of Lords on Tuesday. The promoters had agreed with Thornaby to pay in lieu of profits £200 per route mile for the tramways in their district. Mr. Hamilton, who opposed on behalf of Middlesbrough Corporation, said he would be content to accept a similar clause to that which had been granted to Thornaby in regard to the 325 yards of tramway which would be made within the Middlesbrough boundary under this Bill. This led to a conference, as the result of which it was announced that it had been agreed that the 325 yards of tramway to the east of Middlesbrough should be purchased on Tramway Act terms by Middlesbrough. After formal proof of the preamble had been given, the Bill was allowed to proceed. The effect of the agreement appears to be that the 325 yards of new line in Middlesbrough will come under the purview of the provisional order of 1897, and be purchasable by Middlesbrough concurrently with the other lines, and that the tramway in Thornaby will, for the purposes of the order of 1897, form a portion of the existing system. The question of the payment to Middlesbrough, on the basis of the promoters' arrangement with Thornaby should, it was agreed, form the subject of future negotiations.

Raworth's Patents.—It is stated that six tramway undertakings have decided to adopt Raworth's patent demi or one-man car. Two of these have already been received at the Skircoat depôt for eventual use between the Post Office and the Old Station at Halifax, where a trial trip was made in one of them last week. The great advantage of this car is that it is inexpensive to work. One man can do both the driving and the conducting. He stands at what is for the time being the front of the car. There is an entrance at each end, and at the back end the gate is kept shut and the steps folded up, so that passengers can only be admitted through the opening where the driver is. No one can get out or in while the car is in motion, as any attempt to lift the bar at the exit at once pulls back the speed lever and stops the car. The fares can be dropped into an ordinary fare box, either on entering or leaving the car, and the driver is able without difficulty to exercise a strict check on the number of passengers. The car, which is, of course, of the single-decker variety, will hold 20 passengers. Patent motors and controller are also being used. If the car is going up hill it does not require so much current as an ordinary car, as it is only half the weight; and when it is running down, instead of its grinding up wheels and brakes, the motors turn into generators and generate current, which goes back into the overhead lines to help the other cars. One object of this trial trip was to register the amount of current saved by the patent motors and controller, and the results are said to have been very satisfactory. It is expected that, compared with an ordinary car, which weighs double and requires two men, the saving will be one half, while as the new cars are fitted with regenerative control, it is anticipated that the cost will be further reduced to one-third.

Metropolitan Railway Co.—At the meeting of the St. Marylebone Borough Council the Legal and Parliamentary Committee presented a report stating that they had received a further letter from the engineer to the Metropolitan Railway Company, with reference to the company's proposals to erect an electrical sub-station in Upper Baker-street. The company are very anxious to proceed with the erection of the sub-station, and state that, unless the work can be proceeded with at once, there will be considerable delay caused in running the electric trains over the railway. Although the company feel sure that building shops at the north end of Upper Baker-street will not be remunerative work for them, they undertook to submit for approval a revised plan showing shops facing the street at the side of the sub-station. The committee had also received a further letter from the agent to the Portman Estate, stating that he has had further communication with the railway company as to their proposals, and has seen the engineer, who submitted to him an amended plan, following up the lines of the discussion at the recent conference, by which the company will continue the shops and business premises for the whole length of their buildings on the ground floor at least, and will rearrange the construction of the sub-electrical station so as to only occupy the upper part or back part of their building, and that, under the circumstances, he thinks that this proposal might be accepted. Mr. Seaton, the company's engineer, attended before the committee, and submitted the amended plan showing a new elevation, with shops along the whole length of the buildings, and gave an undertaking that the depth of the shops proposed to be built would not be less than 10ft. and endorsed the plan accordingly. The committee recommended that the Council approve of the proposals of the company to erect a sub-station in Upper Baker-street in accordance with the amended plan.

London County Council.—The Highways Committee submitted a recommendation at Tuesday's meeting of the Council that (*a*) the erection of a pump-house and an outside coal bunker, (*b*) the preparation of the foundations for the turntables and cranes, and (*c*) the making-up of the levels of the road in connection with the generating station at Greenwich, be entrusted to Messrs. Lovatt and Co., who have the main contract, and who were prepared to carry out the work at price ½ per cent. less than the schedule prices specified in their present contract. The expenditure is estimated at £29,000. A further vote of £1,500, beyond the £3,000 already granted, was asked for in order to supply the tools required in connection with the electrical working of the tramways. A sum of £1,250 was applied for to rebuild and extend the car-sheds at Wandsworth. The Highways Committee further recommended that the contract for the sub-station at Greenwich be awarded to Messrs. Lovatt and Co., the work to be completed by the same date as the first portion of the generating station. The cost is put at £18,500. Approval was also asked to an estimated expenditure of £15,000 for the plant required at the sub-station. The receipts for the week ended 9th inst. amounted to £14,117, against £11,187 last year, and for the period from April 1 to that date they totalled £171,048, against £141,966 last year. An elaborate form of top-covered car has been inaugurated on the

Digitized by Google

Peckham route. It was stated at Tuesday's meeting of the Council that in order to realise the tramway estimates for the present financial year a sum of £66,788 more than the receipts of last year would be required, and of this £32,107 had already been realised. It was hoped that the Council's electricity generating station at Greenwich would be at work early in 1906. At the present time the Council is being supplied with current from three stations, costing double the amount it would if supplied from their own generating station, making a difference on the past year of £15,000. The Brixton night trams are not, contrary to reports, to be discontinued, at any rate for the present, though the receipts have been only moderate.

Salford.—The annual report, just issued, describes the new routes opened during the year, and points out that so soon as the lines now being laid along Great Cheetham-street East and Leicester-road are completed—connecting the Bury New-road route with Bury Old-road—a direct route from the districts of Salford and Broughton will be obtained in Heaton Park. The total length of tramways now worked by the Corporation is 59½ miles of single track. Of this 35½ miles are owned by the Corporation. Besides running powers over 5½ miles belonging to Manchester, the following lines are leased to the Corporation: Eccles, 6½ miles; Swinton and Pendlebury, 7 miles; Prestwich, 3½ miles; and Whitefield, 1¾ miles. The total electrical energy used during the year was 6,102 524 units, of which 5,251,055 units were supplied by the Salford electricity undertaking, for which 2d. per unit was charged, less 2½ per cent. discount. The remaining 851,469 units were supplied by Manchester, for which only 1·49d. per unit was paid. The stock of cars on March 31 last was 150, of which 100 were of the double-decked single-truck type and 50 double-decked bogie cars, all having staircases of the reversed type. During the year 20 of the single-truck cars were covered with outer-deck coverings, and have proved of much benefit to the travelling public. The traffic returns show largely increased receipts in the gross, though there has been a decrease in the earnings per car mile, probably as a result of the unfavourable weather of last year. The number of passengers carried, the mileage run, and the traffic receipts were: passengers carried, 36,956,405; receipts, £198,422. 7s. 6d.; earnings per car mile, 10·07d.; miles run, 4,726,446. In the next previous year the figures were: passengers carried, 28,150,675; receipts, £144,486. 2s. 6d.; earnings per car mile, 10·25d.; miles run, 3,380,590. The highest weekly receipts were those for Whit-week, when they amounted to £5,606. 16s. 6d., the sum earned during Whit-week of the previous year amounting to £3,632. 9s. 3d. The year's working to March 31 last has resulted in a gross profit of £60,105. 14s. 11d. The total capital expenditure, including original outlay, amounts to £620,069.

Newcastle.—At the conference between the Tramways Committee and the Tyneside Tramways Company on Saturday the following terms were agreed upon: The Corporation shall run a service of cars beyond Wallsend boundary to Park-road in Wallsend, both on what is known as the low and high lines, and they shall retain their own drivers and conductors. This means linking up Wallsend with the Newcastle system. The Corporation may increase their service with Wallsend at their option. The Corporation to pay in the way of rent for the Wallsend line four-fifths of ½d. for every passenger carried, the sum to be reduced *pro rata* in respect to workmen and children. The fares charged on the through traffic to Wallsend will be ½d. for every half mile, but no fare in Wallsend will be charged less than 1d. The Tyneside Tramway Company will run a car with their own driver from North Shields through to Stanhope-street, or some other point on the Stanhope-street route, but each car is to be in charge of a Corporation conductor from the Wallsend boundary. The car is to be run every 16 minutes to and from Newcastle. This will work in with the present Corporation eight minutes' service, and a Tyneside Tramway Company's car will take the place of one of the Corporation cars. The Corporation to retain the whole of the receipts taken on account of passengers carried in the Newcastle area, and in turn to pay over to the company 2d. per car mile for the rent of car and use of driver. The company undertake to run punctually their cars to the satisfaction of the Corporation, and all cars have to be maintained in good order to the satisfaction of both parties; to be free from advertisements similar to the Newcastle cars as far as possible. With reference to Gosforth Park traffic, the Corporation undertake to look after all the race traffic to Gosforth Park from the Central Railway Station, the special fares to be divided according to the length of mileage run on the two systems, which is about ten-seventeenths for the Corporation and seven-seventeenths to the Tyneside Tramway Company. The company to run not more than four cars on their own lines from Lansdowne-terrace boundary to Gosforth Park. The Corporation undertake to run on ordinary days at least one car every hour to Gosforth Park, and to increase such service as the traffic requires; all-through traffic fares to be divided in proportion to mileage. The agreement to last 10 years, and to be revised every five years afterwards. During the continuance of the agreement neither party shall, without the consent of the other, make any application to Parliament, or to the Board of Trade, or the Light Railway Commissioners, in relation to running, fares, or traffic facilities generally, over the lines of either party, for alteration of powers obtained at the present session of Parliament. This agreement was submitted to the House of Commons Committee on Tuesday, when the matter was adjourned until to-day, another point arising. The committee had suggested that the parties should draw up and submit a clause providing that no increased value should accrue in case of sale from the granting of the running powers. The Corporation of Newcastle, not being the purchasing authority, could not acquire the undertaking of the company, and if the Corporation of Wallsend should in the future desire to purchase the undertaking they would obtain no benefit from the agreement, not being parties to it. Counsel are to formally draft the agreement for incorporation in the Bill, and the provision in regard to purchase is to form a separate clause.

LIGHTING AND GENERAL.

Hove.—The Hove Electric Lighting Company are about to extend their mains.

Acton.—The subject of lighting the courts has been referred back to committee.

Shildon.—The Northern Counties Electric Supply Company are making a start. A site for a station has been surveyed.

Electric Supply Corporation, Limited.—Allotment letters of the issue of 46,600 shares of £5 each were posted on Monday.

Falmouth.—The Empire Electric Light and Power Company intend to apply for a provisional order with regard to Falmouth.

Margam.—The agreement entered into with the South Wales Electrical Power Distribution Company for the supply of electric current is being revised.

Poplar.—The freehold of premises abutting on Eliza-place, Wick-lane, is to be acquired at the price of £1,400 as a site for the proposed northern sub-station.

Harpenden.—The Mutual Electrical Supply Company intend to apply for a provisional order to supply electricity within the Urban District Council's area.

Swansea.—The Town Council have decided to carry out, when necessary, certain works in connection with switches and cables at an approximate cost of £500.

Southill Nether.—Under their recent Bill the Council will acquire powers to build a refuse destructor, and its construction is to be taken into immediate consideration.

Poplar.—The Borough Council have resolved to form a reserve fund with the profit of £4,474 made by their electrical installation during the past financial year.

Louth.—The Town Council have confirmed the agreement with Messrs. Handcock and Dykes as consulting engineers on terms which the mayor said were favourable.

Wolverhampton.—The Town Council have approved of extensions of the electric lighting mains in Waterloo-road from Whitmore Hill to Christ Church, at a cost of £750.

Stoke Newington.—The Council will support the London County Council's proposed application to Parliament re wiring and fitting of consumers' premises for electric light.

Cardiff.—With regard to the erection of an electric distributing sub-station for the docks, it has been agreed to accept tenders subject to the approval of the Local Government Board.

New Address.—Messrs. Rashleigh Phipps and Co. are moving their business of artistic electric fittings, etc., to larger premises at 147, Oxford-street, on Saturday next, the 23rd inst.

Surbiton.—Messrs. Callender have obtained permission and directions to lay cable in Ewell-road at a cost of £449, a road at present outside the area comprised in the electric lighting order.

Holidays.—We are informed that the Brook Green Works of the Robertson Electric Lamps, Limited, will be closed for the annual holidays from Saturday, July 30, until Monday, Aug. 8.

Oban.—The arc lamps are to be lighted from Aug. 1. A main is to be extended for private lighting at an estimated cost of £75, and the public lamps along the route converted to electric lights.

Hindley.—Offers from the Lancashire Electric Power Company and the South Lancashire Tramways Company, Limited, for supplying electrical energy to the township are under consideration.

Goole.—An enquiry has been held into the application of the Urban District Council for sanction to borrow £1,000 for the purchase of property for the purpose of electric lighting and a depôt.

City of London Electric Lighting Co.—Warrants in payment of dividends on account of the distribution for the year 1904 on this company's preference and ordinary shares have been posted.

Hucknall.—The Urban District Council are conferring with the National Electric Construction Company, Limited, and the Southern District Electricity Corporation with regard to electric lighting.

Dewsbury.—The tradesmen's association have written to the Corporation stating that the charges for electricity in Dewsbury were in excess of neighbouring towns, and asking that a reduction be made.

South London Electric Supply Co.—The company reports that the accounts for the half-year ended June 30 show a net profit of £14,149 against £5,210 for the corresponding six months of last year.

Abingdon.—The Abingdon Electric Supply Company intend to apply for a provisional order to authorise them to supply electricity for public and private purposes within the area of the urban district and borough.

Chichester.—The Board of Trade's approval of the draft deed of transfer of the electric lighting order, as slightly altered, has been accepted by the Town Council, and referred to the company's solicitor for approval.

Hornsey.—The Borough Council have decided to borrow £75,083, at 3¾ per cent. interest, repayable in half-yearly instalments, to cover the cost of road widenings, road improvements, and electric lighting extensions.

SS. "Caronia."—We are informed that the United States metallic packing is to be fitted to all the rods on the main and auxiliary engines of the above steamer of record size, which has just recently been launched at Clydebank.

Redditch.—The Urban District Council intend to apply for sanction to a further loan of £7,500 to meet the expenses of installing additional steam plant. A motion to employ a consulting engineer has failed to pass in committee.

Digitized by Google

Scarborough Telephones.—The Municipal Telephones Sub-Committee have now reported to the Corporate Property Committee their decision to defer further consideration of the question of establishing a system of municipal telephones in the borough.

Friern Barnet.—The Electrical Supply Company intend to apply for permission, under the Council's provisional order, to supply electric light within the Council's area. Application is to be made to extend the time of the Urban District Council's order.

Durham College of Science.—Matriculation and exhibition examinations begin Sept. 26 for the departments of mechanical and marine engineering, naval architecture, electrical engineering, mining, metallurgy. Particulars appear in another column.

Rangoon.—At a recent general meeting of the Municipal Committee it was resolved to adopt, on the Local Government's recommendation, the alternating-current system for the electric lighting of Rangoon by Messrs. Darwood and Co.—*Indian Engineering.*

London Electric Supply Co.—The number of units sold for the half-year ended June 30 was 4,494,220, producing a gross revenue of £54,776, compared with 1,927,876 units sold in the corresponding period of the year 1903, producing a gross revenue of £36,825.

Stratford.—The Stratford-on-Avon Electric Supply Company and Mr. G. Vaughan Fowler, of Warwick, and Messrs. Foote and Milne, Limited, of Princes-mansions, 66, Victoria-street, London, intend to apply for provisional orders to supply electricity for public and private purpose.

Harrow Telephones.—The survey of the area to be served by the proposed Post Office exchange has now been completed, and steps are being taken to acquire suitable premises for an exchange, and to carry out the construction of the system of wires as soon as possible.

St. James's and Pall Mall Electric Light Co.—The amount of electricity sold for the quarter ended Midsummer, 1904, is returned at 1,431,553 units, estimated to produce £22,964, as against 1,450,572 units, which produced £23,612 for the corresponding period of last year.

Taunton.—It has been decided, in consequence of the increased demand for the supply of current in the Station-road and Rowbarton district, to at once lay a low-pressure feeder main at a cost of £130. The connections to the mains during the past quarter were equivalent to 304 8-c.p. lamps.

Shildon.—The Northern Counties Electric Supply Company having informed the Council that they had secured a new site for the proposed electric light works, which would be completed without delay, it has been decided not to proceed at present with the action now pending against the company.

Norwich.—The agreement between the Corporation and the National Telephone Company, Limited, with reference to placing telephone wires underground contained a clause for the purchase of the exchange system from the company. This has now been limited to the conduits and manholes in the streets.

Clyde Valley Electrical Power Co.—A committee of the House of Commons on Tuesday adjusted clauses in a group of electric lighting provisional orders relating to Barrhead, Eastwood, and Cathcart, Kilpatrick, Renfrew, Johnstone, and Shettleston. The preamble of the Bill was passed last week.

Shrewsbury.—The accounts of the electricity works for the year ended March 31 show that the costs have been reduced by ·07 per unit, and now stand at 1·85d. per unit. The charges having been reduced, a decrease of ·42d. per unit is shown in the receipts, and £500 has been carried to reserve fund.

Fleetwood.—The suggestion of the electric lighting company of Fleetwood to supply electricity for public lighting purposes in the town at a reduced rate, providing the local Council agree to increase the candle-power in the public street lamps by 50 per cent., has been very well received by the Council.

Swanage.—The Swanage and District Electric Supply Company and the Southern District Electricity Corporation intend to apply to the Board of Trade during the ensuing session of Parliament for provisional orders to empower them to supply electricity for public and private purposes within the district.

Gravesend.—The surveyor is preparing estimates for lighting the bandstand with gas and electric lighting. The Northfleet Council is to be offered a sum of £250 on certain terms for their consent to the extension of the Gravesend electric lighting order, so as to include the urban district and parish of Northfleet.

Hampton.—The District Council have accepted the terms of the General Post Office for an exchange circuit between the public offices and the Kingston post office exchange and a private telephone circuit between the isolation hospital and Dr. Atkinson's residence, a five years' agreement to be entered into in each case.

Govan.—The Town Council have accepted the offer of Messr. Jas. Allan, sen., and Sons, Elmbank Foundry, for the supply of lamp pillars. Mr. Parsons's first annual report on the working of the electricity department is very satisfactory. The capital outlay up to date has been £71,246 and the borrowing powers are £80,000.

Liverpool.—We are informed that the bulk of the £400 000 loan already referred to in these columns, is required for extensions of Lister-drive and other existing stations and mains of the Corporation, principally in connection with additional high-tension system of distribution of 6,000 volts, which was commenced last year.

Lowestoft.—There are now 523 consumers connected to the mains, representing 25,598 8-c.p. lamps. During the month 10 new consumers have been connected, representing 308 8-c.p. lamps. It has been referred to the Electric Lighting Committee to submit an estimate of the cost of lighting the Denmark-road with electric lamps to be fixed to the tramway trolley poles.

Blackpool.—The returns for the month of June at the electricity works show a decrease in the works output of 7,451 units, as compared with the corresponding month last year. For the quarter ending June 30, the works output showed an increase of 69,878 units. The new consumers for the June quarter of this year were 20, as against 30 for the same quarter last year.

Tiverton.—Mr. G. Vaughan Fowler, Warwick, intends to apply for a provisional order under the Electric Lighting Acts for the supply of electricity in the borough. The Council have already adopted a scheme and accepted a tender. Last week they approved of Messrs. Suter's offer to deposit £1,000 as security for the due fulfilment of their electric lighting installation contract.

Cambridge.—The Cambridge Electric Supply Company, Limited, announce a reduction in price of electrical energy from 7d. to 6d. per unit: for any quantity up to 1,000 units yearly, and for any quantity exceeding 1,000 and not exceeding 2,000 units yearly, 6d. per unit, less 5 per cent. discount; 2,000 to 3,000, 7½ per cent.; 3,000 to 5,000, 10 per cent.; and above 5,000 units yearly, 12½ per cent.

Wisbech.—The Electric Lighting Committee's recommendation to adopt an agreement retaining the services of Messrs. Robert Hammond and Son as consulting engineers for the electric lighting scheme will come before a special meeting of the Council shortly. The Board of Trade have approved of the system for the supply of electrical energy for the purposes of the Wisbech Electric Lighting Order, 1901.

Eastern Telegraph Co.—The accounts show, after payment of interest on the debenture stock, dividend on the preference stock, and the interim dividend of £1. 5s. per cent. on the ordinary stock, a balance available sufficient to pay a final dividend of £1. 5s. per cent. and a bonus of £2 per cent., both tax free, on the ordinary stock, making a total distribution of 7 per cent. for the year ended March 31.

Walsall.—An arrangement has been arrived at between the Electricity Committee and the Tramway Committee allowing of a reduction of the price of electricity down to 1½d. per unit to the Tramway Committee for the working of the tramways. The total number of consumers supplied on June 30 last was 350. During the past month the total units generated at the station were 101,514. The total output from the main generators was 98,355 units.

Hull.—An enquiry has been held into an application of the Town Council for a loan of £10,000 required for the purchase of two additional Lancashire boilers and settings; additional mechanical stoking and elevating gear; an additional armature of 510 kw. capacity; and for the construction of a bridge and railway sidings from the adjacent lines of the Hull and Barnsley Railway to the electric lighting station so as to be able to handle the coal more cheaply and expeditiously.

Electric Motors.—We have received a well-got-up and beautifully-illustrated booklet on "Electric Motor Driving," which Mr. S. E. Fedden, A.M.I.C.E., M.I.Mech.E., general manager and engineer of the Sheffield Corporation electric supply department, has drawn up for circulation amongst power users and intending consumers. It not only contains all the necessary particulars, but also a number of flattering testimonials received from many of the motor users in Sheffield.

Dudley.—The report on the year's working of the electric undertaking shows an increased annual output of 470,000 units, subsequent to a reduction in the price of current per unit to 1d. during the 22 light-load hours, and 6d. for the remaining two hours. The income has been £10,662 and the working expenses £5,650. The gross profit was £5,012, of which £4,356 was paid in principal and interest of loans, leaving a net profit of £655. This made a total net profit for the past two years of £1,451.

Lothian Electric Power Bill.—When this Bill came before Mr. Lowther's Committee on Saturday it was explained that the promoters had agreed with the opponents to reinsert the clause which was struck out by the chairman of the House of Lords, the object of which was to give compensation for any injury arising from the escape of electricity. They had resolved upon this course in order to get the opinion of the House of Commons Committee on the subject. The committee agreed to insert the clause, and the preamble of the Bill was proved.

Ashton.—The private consumers at 4d. per unit are to be allowed a discount of 5 per cent. if the account be paid within 21 days of its being presented. The power consumers will be given the option of being charged on the maximum demand system at the rate of 3d. for the first hour's daily use and 1d. after, or the present flat rate of 1½d. per unit. The following figures are available: electricity estimates for 1905, £12,008; actual expenditure for 1904, £11,278. 0s. 4d.; balance to profit and loss account, £1,270. 8s. 9d; amount received for sale of current, £11,046. 12s. 8d.

Electrical Driving and Cotton Mills.—There has just been published in pamphlet form a paper read before the Manchester Insurance Institute on Dec. 8, 1903, by A. Kelly, A.M.I.E.E. (Kelly and Hide, consulting electrical engineers, 36, Dale-street, Liverpool). It is well supplied with illustrations and diagrams, and shows that the advantages of electrical driving in cotton mills has been well appreciated in the United States under conditions which are identical to those obtaining in Lancashire. The manufacturers in this country will no doubt find the little volume useful.

Whitehaven.—Negotiations are still proceeding between the Town Council and the Harbour Commissioners as to the lighting of the harbour, as has been the case for some years now. They now turn upon the question, it appears, whether the Corporation should be held liable for any harbour accident that might result by failure of the lighting or by reason of defective lighting. The best terms the Council can make with the Harbour Commissioners is that this liability should be insured against, and that the Council and the Commissioners should halve the cost of insurance.

Digitized by Google

Stock Exchange.—The Stock Exchange Committee has appointed July 27 special settling day for Metropolitan Railway Company's £500,000 3½ per cent. convertible preference stock, and have ordered the undermentioned securities to be quoted in the official list: Anglo-Argentine Tramways Company, Limited, 120,000 ordinary shares of £5 each, fully paid, Nos. 260,008 to 380,007; British Electric Traction Company, Limited, further issues of 1,235 ordinary shares of £10 each, fully paid. Nos. 232,067 to 233,301; and Metropolitan Railway Company's £500,000 3½ per cent. convertible preference stock.

King's Lynn.—The engineer's last report shows that applications have been received from 10 additional consumers, making a total of 474, and that there are 180 extra lamps, making 19,206 connected for private consumers. He also submitted the following statement—viz.: Units generated, May, 1904, 28,424 (1903, 22,856); units sold to private consumers (light and power). 13,584 (7,603); units sold at power rates, 9,059 (3 427); cost of fuel, stores, repairs, and wages at station, £118. 15s. 2d. (£119. 8s. 10d.); cost of units generated, 1·0027d. (1·2542d.); wages of lamp-lighters and outside staff, £28. 10s. 9d. (£19. 19s. 7d.).

Eastern Telegraph Co.—The revenue for the six months ended March 31 amounted to £635,884, from which are deducted £175,160 for the ordinary expenses and £40,759 for expenditure relating to maintenance of cables, etc., leaving a balance of £419,965, to which is added £32,867 brought from the preceding half-year, making £452,832. After placing £8,000 to the reserve fund for maintenance of ships, and £170,000 to the general reserve fund, a final dividend of 1¼ per cent. is recommended on the ordinary shares, and a bonus of 2 per cent., making a total distribution of 7 per cent. for the year. This will leave £1,233 to be carried forward.

Aberdeen Telephones.—At a recent joint meeting of the Finance and Streets and Roads Committees, the amended agreement, which had been sent back from the National Telephone Company, as to the laying of underground wires for the telephone service in Aberdeen, was considered. It was reported that Mr. Gaine, the general manager of the National Telephone Company, had made very considerable and material alterations on the Edinburgh agreement. After discussion, the joint committee unanimously resolved to recommend that the Council should make no departure from the original agreement which was submitted and was known as the Edinburgh agreement.

Finchley.—The Electrical Committee reported last week that they had expended out of the £17,000 loan £3,347 for a kilowatt set, £289. 7s. for switchboard extension, £700 for a new boiler, £226 for two superheaters, and £49. 15s. for a temporary iron building. They also recommended that the contract with the Callender's Cable and Construction Company for mains included in the extension loan of £17,000 be continued at existing rates, with substitution of "7½d." for "6½d." as the price of copper per pound owing to rise in price since acceptance of original tender, such arrangement to be subject to revision at the end of 12 months from the date of acceptance.

Dundee.—At a special meeting of the Town Council a draft agreement submitted by a company to be promoted to supply electric power to millowners and manufacturers in the city was considered. The capital of the proposed company is a quarter of a million, and they offered to supply power at ¾d. to 1½d. per unit, but not to interfere with the city's present method of supply. The city's electrical engineer reported against the scheme on the ground that, with a new power station, which would have to be erected in a short time, and the present plant, the city could supply power on better terms and in better circumstances than a private company. The Council declined to enter into an agreement with the promoters.

Mackenzie and Moncur, Limited.—We are informed by Messrs. Mackenzie and Moncur, Limited, Edinburgh, that they have added an electrical engineering department to their business under the supervision of Mr. A. Donald Mackenzie, who has been chairman of the Electric Lighting Committee of the city of Edinburgh since its inception in 1894. Mr. Mackenzie will be assisted by Mr. J. A. M'Laren, of the late firm of M'Aulay, Clark, and M'Laren, electrical engineers, 10, Dixon-street, Glasgow, who has had a large and varied experience in mechanical and electrical engineering in all its branches. The company have already received instructions to instal electric light in Appleton House, Sandringham, the residence of Prince Charles of Denmark.

"Thieves Waste Their Valuable Time."—Under the above heading the *Daily Dispatch* comments upon an attempt to melt some of W. T. Glover and Co.'s cables as follows: "Some thieves have had a trying experience in Trafford Park. A quantity of fire-resisting electric cable was carried away and put on a fire to burn, so that the insulating material over the copper might be burnt away, and the copper itself more readily melted for sale. The thieves apparently had not seen a guarantee given by the makers that the covering would resist fire, and it is feared that a considerable amount of time, patience, bad language, and fuel were used before the futility of the operation was discovered. The cable was found in a very sooty condition, but otherwise uninjured."

Caerphilly.—The Bill to confirm a provisional order of the Board of Trade for the supply of electric light to Caerphilly and district came before Mr. Agg Gardener's Select Committee of the House of Commons on Monday. A petition against the Bill had been lodged by the Rhymney and Aber Valleys Gas and Water Company. Mr. Rose, K.C., on behalf of the promoters, said the object of the Bill was to enable the Caerphilly Urban District Council to supply electricity to Caerphilly, Aber, Senghenydd, and Llanbradach, which was the area over which the Council had jurisdiction. It was not intended by the authority to generate their own electricity, but it would be bought from the Electric Power Distribution Company of South Wales. A certain minimum quantity of electricity would have to be taken, and the district it was proposed to supply had a population of about 10,000 people. The committee passed the Bill.

Shoreditch Electrical Exhibition.—It is proposed by the Lighting Committee of this Borough Council to hold an exhibition of electric lighting apparatus, accessories, machinery in motion, etc., at the Pitfield-street Baths in October next. The exhibition will be open for two weeks from Oct. 10 to 22. The Pitfield-street Baths are well adapted for such purposes, being only 15 minutes' walk from the City, within four minutes of the North London Railway Shoreditch Station, and the South London Electric, also the Great Northern and City Electric Railway Stations; the building is close to 'bus and tram routes from the City, Islington, Hackney, and Bethnal Green. Being so easy of access, it is anticipated that many visitors will attend from the neighbouring districts. We are informed that applications for space should be sent in not later than Aug. 15 next, addressed to Mr. C. Newton Russell, borough electrical engineer, Coronet-street, Shoreditch, N.

Hastings.—The Town Council have adopted a report in which the Electricity Committee stated that they had considered the matter of the desirability of establishing an alternative method of charge for current to the existing maximum demand charge of 10s. per 8-c.p. lamp per annum, plus 1½d. per unit for current consumed, the effect of which latter charge the committee find does not seem to be generally appreciated by consumers, and recommended that in future such consumers as express a desire to do so be allowed to take current under what is known as the summer and winter system of charge, by which system a charge of 6d. per unit would be made for the maximum number of units which would be consumed by an entire installation during one hour's burning per day (including Sunday) in each of the two summer quarters, and during three hours' burning per day in each of the two winter quarters, and in addition a charge of 2½d. per unit for all current consumed in any quarter over and above the maximum number of units

Sydney (N.S.W.).—The *Sydney Newsletter* says: "The work of laying on the electrical supply for the lighting of Sydney has been carried along with surprising speed since the weather took up, and both public and private contractors have been somewhat surprised. In point of fact, the work has been closely watched, owing to the methodical and thoroughly well-planned style in which it has been carried out. As a sample of this, it may be mentioned that last week in five days as much as 9½ miles were laid and the whole work of covering and restoring pathway completed. Of course, during the continuous wet weather, and owing to our narrow streets and pathways, a good deal of inconvenience was felt by business people in different parts of the city owing to the extensive disturbance of the footways. Still, the situation was fairly recognised, and the City Council officers expressed themselves as thoroughly satisfied with the efforts of W. T. Henley's Telegraph Works to vigorously execute their contract."

Manchester.—The annual report of the Electricity Committee shows a considerable increase in the demand for electric energy. Two years ago the quantity of current generated was 10 million units; in the year just closed it amounted to 29 millions, owing principally, however, to the completion of the tramways. The total number of units sold for lighting and power purposes was 11,799,214, and for traction 17,125,857. As barely 17½ millions were sold during the previous year, it is readily seen what splendid progress has been made. The plant has now capacity for generating 40 million units. The sinking fund and interest in connection with the department during the last 12 months amounted to £106,000. The price of current has been reduced, and the committee have set aside £25,000 for renewals and suspense account, and have added £6,000 to the reserve account, which now stands at £32,000. The total length of street mains now laid is about 285 miles. The area supplied at present is about 20 square miles, but the Corporation have authority to extend the area to 44 square miles.

Burton-on-Trent.—An exhibition of electrical appliances and motors was opened in the town hall last week by the Mayor (Mr. A. J. Roberts), who said that they now had 24,135 8-c.p. lamps, an increase of 12 per cent. on the year, and there were applications in hand for 459 more, equivalent to 15 per cent. increase There were also 33 motors among 18 consumers, amounting to 230 h.p., which, together with applications in hand, made an increase on the year of 255 per cent. for motor power. There was a good field for motor power in Burton, and its advantages and cheapness were only required to be known for a more extensive adoption. The trams afforded a practical illustration of the benefits of electrical power. The exhibitors included Mr. J. Richards, 48 and 49, High-street; Langton-Davies Motor Company, Limited; the United States Metallic Packing Company, Bradford; Mr. T. Williams, West Smithfield, London; Messrs. Joshua Pickles and Son, Hebden Bridge; Messrs. F. W. Flower and Co., Shaftesbury; Brush Electrical Engineering Company; Mr. W. H. Allen, Bedford; Barnett and Soans, Arcade-buildings, Burton, and George-street, Kettering; Mr. C. M. Livens, High-street, etc.

Alloa.—The negotiations between the Town Council and the British Electric Plant Company have resulted in an offer by the Council to lease the electricity undertaking to the British Electric Plant Company for the remaining years of the agreement on the basis that the company pay interest on the cables, and after the first six years pay sinking fund in addition. The original terms made with the company were £9 per kilowatt and 1½d. a unit. The Council subsequently requested a reduction of the kilowatt charge to £6, and after prolonged negotiations the company definitely intimated that they were not prepared to lower the kilowatt charge, but, if the Council adopted a new system of charging at a fixed rate per ampere per quarter, the company would be prepared to reduce the unit rate to 1d., conditional on the Council selling the current at 1½d. in addition to the fixed ampere charge. The Council consulted Mr. Hansen, electrical engineer, Stirling, on this point, and he drew up a statement showing what the chief consumers had paid for the previous year and what they would have paid on this basis, and the Council in consequence offered as a

Digitized by Google

counter proposal that if the company would give a flat rate of 2½d., they would sell to the public at an average flat rate of 3½d. per unit. This was not accepted.

Swindon.—The following are extracts from Messrs. Lacey and Co.'s recent report: "Having carefully considered the requirements of the area, we advise that the system which will give the best results, both from an engineering and commercial point of view, is a system of direct-current three-wire supply, with a difference of potential of 440 volts between the outer cables throughout the whole area, and a 220-volt service to customers. The generating station, if properly designed, will allow of a low capital expenditure, and the plant can be such as to secure immunity from failure. The pressure of supply is sufficiently low to minimise trouble in both generating machinery and distribution. Further, the use of accumulators for storage purposes provides a most valuable safeguard, which is practically unattainable with alternating-current plant. The system of distribution will be such as to give the least possible transmission loss of any system in your particular case, and both the first cost and cost of future extensions will be exceptionally low, if sufficient care be given to the initial arrangement. The annual works costs for current production will be kept at a minimum, as the ease of regulation and the absence of transformers, of any complicated apparatus for maintaining the required pressure, will enable the system to be worked with the least possible amount of skilled labour, and at the same time avoid the many attendant losses between the generation and the consumption of current. The plant could be so designed and arranged that additional machinery can be put down without interference with the original installation or system of supply."

St. Marylebone.—The Electric Supply Committee last night presented the following report: "We have considered in their financial bearings estimates of expenditure by the Electric Supply Committee, based upon the amounts of the tenders recommended by that committee to the Council for acceptance in connection with the erection and fitting up of the electric generating station, and submit the same to the Council. This expenditure will be chargeable against the loans to be obtained for the purposes of the undertaking, and if approved by the Council, the acceptance of the tenders should be subject to the sanction of the London County Council to the amounts proposed to be borrowed for the several purposes. F. G. Minter, High-street, Putney, S.W., building new generating station, including constructional steelwork, £57,524; C. A. Parsons and Co., Newcastle-on-Tyne, electrical machinery, including electric crane and cooling towers, £79,598; St. Helens Cable Company, Limited, Warrington, cables, £78,165. 12s. 9d.; Babcock and Wilcox, Limited, Farringdon-street, E.C., steam generating plant, £55,202. We considered as to the desirability of taking any further steps for securing the advance from the County Council of £1,415,000 in October next. The County Council have given an undertaking that the money shall be forthcoming at the date required, and that it will be provided, in the first instance, by an issue of London County Council Bills, but the terms, etc., were left for further consideration. We ascertained that the terms proposed were very favourable, and we authorised the town clerk to make any formal application which the Finance Committee of the County Council might desire."

Oldham.—From the accounts for year ended March 25, 1904, we obtain the following particulars: Loans—sanctioned, £244,510; borrowed, £223,175; repaid, £13,094. Capital expenditure, 1903-4 £242,974, 1902-3 £216,882; revenue from electricity supply, £25,431 (£25,764); revenue from meter rents, etc., £386 (£408); total revenue, £25,818 (£26,172); total costs, £12,815 (£13,560); gross profit, £13,003 (£12,612); percentage of ditto to capital (averaged), 5·65 per cent. (7·75 per cent.); interest on loans, less interest receivable, £7,868 (£4,429); sinking fund, £5,906 (£2,854); percentage of ditto to capital (averaged), 2·57 per cent. (1·75 per cent.); financial result, loss £771 (profit £5,329); 8-c.p. lamps connected, 58,207 (54,154); units sold—private supply, 848,095 (762,213); public supply, 17,362 (16,972); traction, 2,177,309 (2,090,125)—total, 3,042,766 (2,869,312); units sold per 8-c.p. lamp (averaged), 15·4 (14·4); maximum load, 1,765 kw. (1,743 kw.); load factor, 19·62 per cent. (21·68 per cent.); capacity of dynamos, 5,232 kw. (5,232 kw.); statutory maximum price, 8d. (8d.); price charged—private supply, 4d. to 1½d. (4d. to 1½d.); public supply, 2½d. (2½d.); power and heat, 2d. to 1½d. (4d. to 1½d.); traction, 1½d. (2d., 1⅞d., and 1½d.); average price obtained—private supply, 3·29d. (3·41d.); public supply, 2·50d. (2·50d.); traction, 1·50d. (1·69d.); population of area of supply, 1901, 137,238 (137,238). Generation and distribution costs—coal and other fuel, 1903-4 £5,566, per unit 0·44d. (1902-3 £5,975, per unit 0·50d.) – 0·06d.; oil, water, and stores, £702—0·06d. (£551—0·05d.) + 0·01d.; wages, £2,658—0·21d. (£2,199 – 0·18d.) + 0·03d.; repairs and maintenance, £1,321 — 0·10d. (£2,617 — 0·22d.) – 0·12d. — works costs, £10,247—0·81d. (£11,342—0·95d.) – 0·14d. General costs—rents, rates, and taxes, £1,260 — 0·10d. (£1,197—0·10d.); management expenses, £1,308—0·10d. (£1,021 —0·08d.) + 0·02d.—total costs, £12,815—1·01d. (£13,560—1·13d.) – 0·12d.

Salford.—The borough electrical engineer, Mr. C. D. Taite, in his annual report states that the whole of the machinery has been taken over from the contractors, and that the engines continue to give satisfactory results. During the year 7,321 yards have been added to the distributing mains previously in use. Besides 156 new consumers connected to the main, there was a large number of extensions to installations by old consumers. The new connections are equivalent to 19,009 8-c.p. lamps and 997 h.p. in motors. Amongst the new tenders accepted is one by the committee for the supply of power to some 3,000 b.p. to be installed at the new dock of the Manchester Ship Canal Company, together with current for the lighting. It is estimated that at the end of five years the annual consumption at this dock will not be less than 1¾ million units. The motor-hiring business made great progress. There are out on hire 105 motors, aggregating 954 b.h.p., as compared with 39 motors of 336 b.h.p. in the previous year. The number of consumers who have motors on hire is 66. The gross profit for the year was £42,860, being at the rate of 8·36 per cent. on the average capital invested. This has been appropriated as follows: interest on loans, £16,020; sinking fund, £15,066; net profit, £11,774. This was thus allocated: depreciation and reserve, £8,000; debit balance from 1902-3, £2,394; contribution in reduction of rates, £1,380. The total paid to the sinking fund since the commencement of the undertaking now amounts to £47,999. The number of units sold had increased from 4¾ million units to 7½ million units, or 58 per cent., while the maximum load had only advanced from 2,490 kw. to 3,200 kw., or 28·5 per cent. The average price for private supply had fallen to 2·36d., due to the development of the demand for electricity for power purposes. The total capital expenditure to March 31 last was £530,446, of which £42,738 was expended during the financial year. The sale to lighting consumers increased from 908,354 units for the year ending 1903 to 1,140,244 units for the year just ended. The units sold for tramway purposes had increased from 3,370,434 units the previous year to 5,251,055 for the past year.

London Gazette.—The last day for receiving proofs in the estate of Thomas Williams, electrical engineer, 54, Bridge-street, Llandaff, lately residing at 13, Despenser-street, Cardiff, Glamorgan, is July 30; Mr. S. David, official receiver, 117, St. Mary street, Cardiff. Mr. A. Mackintosh, 24 Railway-approach, London Bridge, S.E., has been released from trusteeship in the estate of John Pierrepont Child, electrical engineer, 150, Powis-street, Woolwich, and 109, Piedmont-road, Plumstead, Kent. Mr. W. F. J. Hunt, Midland Bank-chambers, High-street, Southampton, has been released from trusteeship in the estate of Edwin Ward (trading as E. Ward and Co.), plumber and electrician, 38, Osborne, Southampton, late of 108, Bevois-valley and 47, Lodge-road, Southampton. The first meeting of creditors in the estate of the Electro-Voelker Syndicate, Limited, 65, George-street, Croydon, Surrey, will be held at 11.30 a.m. on July 29, and the meeting of contributories at 12.30 p.m. on July 29, at 24, Railway-approach, London Bridge, S.E. The first meeting in the estate of Frederick William Parkes and Edward Sadleir (trading as Parks and Sadleir), electrical fitters and engineers, The Dingle, Colwyn Bay, will be held at 11 a.m. on July 27, at Crypt-chambers, Eastgate-row, Chester. The last day for receiving proofs in the estate of the Electrical Timber Seasoning and Preservation Company, Limited is Aug. 4; Mr. Harold de Vaux Broughan, official receiver, 33, Carey-street, Lincoln's-inn, W.C. The partnership between Percival Joseph Buddery and Horace William Van der Pant, electrical and motor engineers, 5, Kingston-road, Wimbledon, Surrey, trading as Percy J. Buddery and Co., has been dissolved by mutual consent. A bankruptcy petition has been presented against Warner and Co., 12, Holbein-place, Sloane-square, London, builders and electricians, and will be heard at 11.30 a.m. on July 28. The petition to reduce the capital of the Edison and Swan United Electric Light Company, Limited and Reduced, from £1,000,000 to £941,090, is directed to be heard before Mr. Justice Buckley on July 26. The Electrical Machinery Developments Company, Limited, will be wound up voluntarily; Mr. F. W. Lowther, 151, Cannon-street, London, E.C., has been appointed liquidator. The London Telegraph and Steam Gauge Electric Company, Limited, will be wound up voluntarily; Mr. J. R. Reedman, 2, Bradley-street, Canning Town, E., has been appointed liquidator.

London County Council.—On Tuesday it was agreed to lend the Islington Borough Council £15,636 and the Poplar Borough Council £25,000, and sanction was granted to the first-named Council to borrow £15,675 for electric light installations. The Highways Committee reported that they stated on June 21, 1904, that it would be necessary, in connection with the establishment of the Council's electricity generating station at Greenwich, to proceed at an early date, in connection with the provision of a water supply for the station, with (*a*) the erection of a pump-house and an outside coal-bunker, (*b*) the preparation of the foundations for the turn-tables and cranes, and (*c*) the making-up of the levels of the road. The Council accordingly on that date authorised them to arrange, during the summer vacation, for tenders for this work to be obtained, and for the necessary steps to be taken to accept such tender as might be considered most satisfactory, and to arrange for the execution of a contract to give effect thereto. The Council also approved of a clause for insertion in the form of contract for the work, providing for it to be carried out within 12 months, and for a penalty of £50 a week in respect of the period by which the time of completion might exceed the time fixed in the contract, and, should the work be completed in less than that time, for the payment to the contractor of a bonus at the rate of £25 a week in respect of the time between the actual date of completion and that specified in the contract. It had since occurred to them that it would be of advantage if this work could be carried out as part of the contract of Messrs. H. Lovatt, Limited, entered into in pursuance of the Council's resolution of May 3, 1904, for the erection of the superstructure of the first portion of the generating station. The work in connection with the erection of the pump-house, etc., must be carried out in intimate connection with the erection of the superstructure of the station, and would be greatly expedited, therefore, if it was placed in the hands of the same contractors. They had ascertained that Messrs. Lovatt were willing to carry out the additional work at prices ½ per cent. less than the schedule rates specified in their present contract. Messrs. Lovatt, Limited, were also prepared to carry out the work upon the conditions approved by the Council on June 21, 1904, as regards the time of completion, etc. The offer was accepted. In another report, which is to be considered next week, the committee will also recommend that the offer of Messrs. H. Lovatt, Limited, to carry out, at a reduction of ½ per cent. on the schedule rates under their existing contract with the Council for the erection of the superstructure of the first portion of the Greenwich generating station, the erection of the electricity sub-station at Greenwich, be accepted.

Earl's Court.—Few of the visitors who are daily enjoying the unusual summer amongst the sights of the Italian Exhibition are probably aware of the largely extended use to which electricity has been put this year, both in the electric lighting, concealed and otherwise, and in the working of the various entertainments. A number of extensions have this year been carried out under the supervision of Mr. W. R. Wynne, the chief electrical engineer of London Exhibitions, Limited. Although the load on the station is now 525 kw., equal to 15,000 8-c.p. lamps, a considerable supply is also taken from the Brompton and Kensington Company's mains. Quite recently 1,600 5-c.p. lamps were placed around the eaves of the Queen's Palace with admirable effect. This is a permanent installation on the three-wire system, in casing enclosed in zinc troughing which has been specially passed by the London County Council. This installation being rather far from the engine-house, current is supplied by the above-mentioned company. The old theatre has been entirely rewired for "Venice by Night." The night effect has been rendered especially true to nature. The ceiling, 80ft. from the ground, is dotted with tiny stars, represented by a number of 5-c.p incandescent lamps on 10 circuits. The canals are lighted by incandescent lamps fitted in iron brackets fixed to the walls. On the streets and piazzas cast-iron standards have been erected. Each standard bears three lanterns, in shape imitating gas lamps, but in reality containing a 100-c.p. lamp each. All the shops are wired on the usual house-lighting rules. There is a 100-volt supply from insulated cables laid in iron tubes underground, in seven circuits, controlled by the old switchboard in the theatre. This installation contains 24 100-c.p., 50 50-c.p., and hundreds of other incandescent lamps, varying from 5 c.p. to 32 c.p. The panoramic effects are obtained by arc lamps. All the side shows are supplied from the station by meter. We note that the macaroni factory is driven by a direct-current motor of 200 volts. A mercury contact switch of peculiar construction, supplied by Harrod's Stores, controls the aurora borealis in "Furthest North." The effect in the electric fountains is due to a large number of arc lamps fixed high above the water. The blue effects in the Blue Grotto are due to Nernst lamps. The beautiful "Electric Butterflies" are produced by means of a variety of incandescent lamps on the bodies of the performers, controlled by a switchboard in the wings. An idea of the extensive use made of electric light this year, as far as the side shows are concerned, may be gathered from the fact that the Roman Forum, in a comparatively very small space, has 82 8-c.p. lamps, and St. Peter's uses four 100-c.p. and two 200-c p. lamps, while four arc lamps are required for taking short-exposure photographs, etc. Mains have recently been laid for charging the four electric launches on the lake. All the cables laid are 600 make, and they are laid in wood casing treated with fire-resisting compound.

PROVISIONAL PATENTS, 1904.

JULY 11.

15396. **Improved means for protecting the insulation of electric light flexible cords from dust, flies, and such like vermin.** John Young, 21, Gloucester-walk, Campden-hill, Kensington, London.

15419. **Improvements in laminated iron sections for alternating-current transformers.** John Howarth Bainbridge, 24, Endsleigh-villas, Southall, Middlesex.

15411. **Automatic firing apparatus for guns and firearms having electrical or electro-mechanical ignition.** Heinrich von Péchy and Victor Rea, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

15452. **Improvements in systems of electrical distribution.** John Sedgwick Peck, Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Aug. 8, 1903, being date of application in United States.) (Complete specification.)

15453. **Improvements in or relating to electric arc lamps.** Charles Oliver, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

15455. **Improvements in relays for automatic circuit breakers.** Michael Birt Field, Charles Cornfield Garrard, and Ferranti Limited, 18, Southampton-buildings, Chancery-lane, London.

15467. **Improvements in vapour electric conductors.** Osias Otto Kruh, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, July 11, 1903, being date of application in United States.) (Complete specification.)

15468. **Improvements in vapour electric lamps or rectifiers.** Ezechiel Weintraub, 83, Cannon-street, London. (Date applied for under Patents Act, 1903, July 11, 1903, being date of application in United States.) (Complete specification.)

15469. **Improvements in and relating to vapour electric conductors** Osias Otto Kruh, 83, Cannon-street, London. (Date applied for under Patents Act. 1901, July 13, 1903, being date of application in United States.) (Complete specification.)

15472. **Improvements in electric incandescent lamps.** Armand Frey, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

JULY 12.

15517. **Dynamo-electric engines.** Julius Lommatzsch, Bernhard Mensch, and Oscar Siegert, 81, High Holborn, London. (Complete specification.)

15495. **Improvements in dynamo-electric machines for regulating the charge and discharge of storage batteries used in combination with main generators.** The Lancashire Dynamo and Motor Company, Limited, and Robert Stafford McLeod, 34, Castle-street, Liverpool.

15512. **An improved lid for accumulator and other acid-containing boxes or tanks.** Edward James Clark and Hart Accumulator Company, Limited, 165, Queen Victoria-street, London. (Complete specification.)

15529. **A system of wire entanglements and electrically-operated apparatus for the protection of the mouth of a harbour in war time.** Edward Gordon Stuart McClellan, 22, Southampton-buildings, Chancery-lane, London.

15551. **Improvements relating to the prevention of fires caused by short-circuits or by injury to electric conducting wires or cables.** Otto Wilhelmi, 37, Essex-street, Strand, London.

15561. **Improvements in indicators for electric oscillations.** William Phillips Thompson, 6, Lord-street, Liverpool. (Gesellschaft für drahtlose Telegraphie m. b. H., Germany.) (Complete specification.)

15563. **Improvements in electromagnetic signalling devices for operating two or more alternate signals.** Joshua Willis, 6, Lord-street, Liverpool.

15567. **Improvements in electric or telephonic transmission.** Henri Carbonnelle, 7, Ely-place, Holborn, London. (Complete specification.)

JULY 13.

15581. **Improvements in telephone, telegraph, and other call systems.** Alfred Charles Brown, 7, Queen's-square, Finsbury-avenue, London.

15599. **Metallic thermometrical electrical indicator.** Alexander Beard Thompson, 11, Cheapside, Oldham.

15612. **Improvements in means for changing or reversing the direction of electric currents.** Edward George Paul Bonsfield and the Ozonised Oxygen Company, Limited, 4, South-street, Finsbury, London.

15614. **Improvements relating to dynamos used with other dynamos or cells.** Walter Langdon Davies and Alfred Soames, 24, Southampton-buildings, Chancery-lane, London.

15616. **Improvements in single-phase alternate-current motors.** Crompton and Co., Limited, and Rudolf Goldschmidt, The Arc Works, Chelmsford, Essex.

15617. **Improvements in electric contact or supporting gears.** Crompton and Co., Limited, and Ernest William Abbott, Arc Works, Chelmsford, Essex.

15618. **Improvements in and relating to electric circuit breakers.** Crompton and Co., Limited, and Robert Charles Harris, Arc Works, Chelmsford, Essex.

15626. **Improvements in dynamo-electric machines.** William Brooks Sayers and Mavor and Coulson, Limited, 46, Lincoln's-inn-fields, London.

15627. **Improvements in electric clocks.** George Bennett Bowell, 40, Chancery-lane, London.

15632. **Improved system of protection for parallel electric feeders.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

15634. **Improvements in systems of electrical distribution.** Samuel Ferguson, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, July 13, 1903, being date of application in United States.) (Complete specification.)

15637. **Improvements in regulating mechanism for arc lamps.** William Tichborne Upton, John Edward Elliott, and Hubert Bevan Pratt, 11, Southampton-buildings, Chancery-lane, London. (Complete specification.)

JULY 14.

15646. **Improvements in and in the production of electrical fuse, distribution, and like boxes.** Verity's, Limited, and Arthur Edgar Gott, 11, Burlington-chambers, New-street, Birmingham.

15648. **Improvements in electric motor starters and electrical resistances.** Verity's, Limited, and Arthur Edgar Gott, 11, Burlington-chambers, New-street, Birmingham.

15651. **Improvements in lifeguards for electrically-propelled vehicles or the like.** Edgar Ashley Greaves, 9, Tempest Hey, Liverpool.

15677. **"Shouldergrip" telephone receiver rest.** William Henry Danson, 21, Cole-street, Borough, London.

15691. **An improvement in electric lighting and advertising.** Alfred Edward Mead, 51, Leinster-square, Hyde Park, London.

15692. **An improvement in collecting electric currents from armatures of unipolar dynamo-electric machines.** Francis Edward Elmore, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

15701. **Improvements in instruments for determining the drop of potential in electric transmission systems.** Allgemeine Elektricitäts-Gesellschaft, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, July 14, 1903, being date of application in Germany.) (Complete specification.)

15699. Improvements in or relating to electrical resistances. Wilhelm Boehm, 18, Buckingham-street, Strand, London. (Complete specification.)

15704. Improvements in electricity meters. William Morris Mordey and Guy Carey Fricker, 46, Lincoln's-inn-fields, London.

15708. Means for electrically controlling phonographs and cinematographs in combination. La Société L. Gaumont et Cie., 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, July 17, 1903, being date of application in France.) (Complete specification.)

15712. Improvements in or connected with wireless signalling. Louis Heathcote Walter, 92, Victoria-street, Westminster, London.

JULY 15.

15732. Improvements in electric light fittings. Verity's, Limited, and J. Sothcott, Plume-street, Aston, Birmingham. (Complete specification.)

15770. Improvements relating to boxes, covers, or containing cases for electric switches, fuses, and the like. Thomas Herbert Marsh and Albert Brown Mudie, 18, Southampton-buildings, Chancery-lane, London.

15771. An improved connector for the armature and commutator of dynamo-electric machines. Siemens Bros., and Co., Limited, and Hereford Berry, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

15772. Improvements in the manufacture of insulated electric conductors and apparatus therefor. Siemens Bros. and Co., Limited, and William Dieselhorst, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

15778. Improved contact stud and switch for use with surface-contact systems of electric traction. William Griffiths and Benjamin Harry Bedell, 22, Southampton-buildings, Chancery-lane, London.

15796. Improvements in or relating to alternate-current distributing systems. Charles Hesterman Merz and Bernard Price, 46, Lincoln's-inn-field, London.

15802. Improvements in or relating to conduits for underground electrical wires or cables. Martyn Judson Stone and Edward Taylor Fenwick, 6, Lord-street, Liverpool.

JULY 16.

15869. Improvements in installations for electrically operating railway points. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, London. (Siemens und Halske Actiengesellschaft, Germany.) (Complete specification.)

15872. Improvements in arc lamps. Georges Viarmé, 7, Southampton-buildings, Chancery-lane, London.

15874. Electrical fire extinguisher. Hans Ruppert, 81, High Holborn, London. (Complete specification.)

15879. Improvements in alternating electric current meters. Allgemeine Elektricitäts-Gesellschaft, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, July 17, 1903, being date of application in Germany.) (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Aug. 4, 1904.

1903.

15218. Electrical apparatus operated by the expansion and contraction of a controlling member. Swanton.

15463. Electric circuit controlling apparatus. Garrard, and Ferranti Limited.

15569. Production of alternating electric currents. Poulsen.

15817. Electrically-actuated musical instruments. Dickson.

15872. Switches and rheostats for starting and controlling electric motors. Hunt.

16113. Mode of and apparatus for producing and detecting Hertzian oscillations. Maskelyne.

17563. Electrical heating devices. Huntley.

21068. Telephone connections on the party-line system. Oppenheimer. (Aktiengesellschaft Mix und Genest.)

1904.

1205. Telephonic apparatus. Höflinger and Wolffhardt.

3737. Electric railway and tramway systems. Shobe and Embley. (Date applied for under International Convention, April 10, 1903.)

4020. Electric switches. Reyrolle.

6116. Electrical apparatus for aiming and shooting practice. Firm of C. Lorenz. (Date applied for under International Convention, Dec. 21, 1903.)

6332. Electro-mechanical cut-outs. Spagnoletti.

6334. Means for automatically controlling the passage of electric currents. Spagnoletti.

7021. Means for controlling electrically-operated elevators. Klein.

8007. Friction gear for driving electrical generators. Whiteman. (Henricks Novelty Company.)

7977. Receiving devices for use in wireless telegraphy. Möller. (Date applied for under International Convention, May 2, 1903.)

11651. Portable insulated support for double-wire electric lines. Collett. (Date applied for under International Convention, Aug. 4, 1903.)

12977. Telephones. Nye and Peck.

13332. Manufacture of electric cables. Beaver and Claremont.

13423. Electrical locomotive. Fairweather. (Brown Hoisting Machinery Company.)

NOTES.

Errata.—In our last issue we noticed the receipt of a book entitled "An Enquiry into and Explanation of Decimal Coinage, etc." The publishers should have been stated as George Routledge and Sons, Limited, London, and not Messrs. Anthony Bros., Limited, as in our last issue. The object of the book is to popularise the decimal system.

The Diesel Oil-Engine.—At a recent consumption trial of a Diesel oil-engine of 160 b.h.p., the extremely low consumption of 0·37lb. of crude petroleum per brake horse-power was obtained. Other fuel comes out as low as $\frac{1}{12}$d. per brake horse-power hour. The use of the Diesel oil-engine seems to be extending, and we note that the City of Birmingham Tramways Company have recently given a repeat order for two engines, each of 160 b.h.p.

Sheffield University.—We note that Prof. William Palmer Wynne, D.Sc., London, F.R.S., F.I.C., senior hon. secretary of the Chemical Society, in succession to Prof. Carleton Williams, has accepted the Firth chair of chemistry offered to him by the council of Sheffield University College. Prof. Wynne is at present professor of chemistry in the school of pharmacy of the Pharmaceutical Society of Great Britain, and was four years ago editor of the *Journal* of the Chemical Society. He will commence his Sheffield duties at the end of September.

The New Magnetic Observatory.—The first contract in connection with the erection of the new magnetic observatory by the Government at Eskdalemuir, Dumfriesshire, has been let to Messrs. Henderson and Duncan, Morningside, Edinburgh. The work embraces the making of a road and some foundations, the provision of a water supply, and building of a boundary wall, and it has to be carried out within three months. This observatory is to replace the one at Kew as far as magnetic observations of the earth's field are concerned.

Bradford Finance.—Alderman J. A. Godwin, the chairman of the Bradford Finance Committee, is to be congratulated on the success of his efforts to keep the financial policy of the Bradford Corporation on sound lines. He has succeeded recently in getting the rates increased 2d. in the £, and at the same time reduced the price of gas supplied from the Corporation works. The net result of these two alterations practically cancels out, but the change is in the direction of sound municipal trading. The general charges are now borne more equally by all the ratepayers, and the users of gas are not penalised for the public good.

Rochdale Accident.—Our attention has been drawn to the fact that our leader in our issue of July 15 might be read as though the electricity department of Rochdale had not records of the positions of their cables in the streets or of the joints in the same. This, of course, is quite an inaccurate rendering, as Mr. C. C. Atchison has complete plans of all his cables in his office. In the case in question, however, the damage was done, not by men directly under the control of the electrical engineer, but by employés in the surveyor's department. We believe we are correct in stating that duplicate records of the positions of mains are sent regularly to the surveyor.

Bombay Lighting.—Bombay has been behind one or two cities in India in taking up electric lighting and power distribution, but there is every sign that now the work is to be carried out on most modern lines, and that electrical energy will soon be available. According to our contemporary, the *Indian Electrical, Mechanical, and Textile News*, it is confidently expected that the current will be available in October. The system of distribution to be used is one suited to a large and straggling area where the demand will be chiefly around certain well-defined centres. Current will be generated at the central station in Wari Bunder at a pressure of 6,000 volts three-phase, and will be transmitted to sub-stations at the chosen centres, where it will be transformed by means of rotary converters to continuous current at 2 × 230 volts, and distributed around the centres by means of a low-tension network of three wires laid solid after the Callender system. The work now being carried out is the transmission line to Tata's Hotel, where the first sub-station will be situated. Afterwards another sub-station in Apollo-street, near the Great Western Hotel, will be equipped, and will serve the business portion of the fort.

The Johannesburg Lighting and Tramway Scheme.—It will interest those of our readers who have not the matter already in their minds to know that the total capacity of the new generating station which Messrs. Mordey and Dawbarn are putting down, as consulting engineers, for the Johannesburg Corporation, is no less than 9,000 kw. Part of the machinery will supply direct current and the other alternating current. The prime movers will be gas-engines worked by producer gas. As regards distribution, the inner area of the town will have a supply on the three-wire, direct-current system, with 460 volts between the outers. In the outlying suburbs alternating current will be supplied from a two-phase system. The voltage on the primary will be 3,000 per phase and the frequency 50. The secondary voltage will be 400 between the two outers of a three-wire system, and in most places only one phase will be available. The first portion of the electric tramways will have 24 miles of track. It is gratifying to note that the bulk of the contracts have been placed with English firms, and that Messrs. Siemens Bros. are supplying the electric plant in the power station.

The Rochdale Arbitration.—The company have emerged very favourably from the arbitration proceedings which have been held to determine the price to be paid for their undertaking by the various local authorities. The award has fallen a good deal below the £205,401 representing the exalted valuation of the concern as submitted on behalf of the company, but they have obtained £35,291 more than the £123,784 which the experts for the local authorities put the value at, exclusive of a sum of £3,600 for street improvements, which is still unsettled. In respect of the main item — the permanent way — the company claimed £103,459, while the authorities estimated the value at £64,142, contending that the track had been indifferently maintained, and was in a very worn condition. Voluminous expert evidence of a conflicting character was tendered on behalf of the respective parties, and in the end the arbitrator has practically split the difference, though the amounts awarded in respect of the individual items do not appear. The amount which the company will receive is slightly nearer to the valuation of the local authorities than to that of the company, but the result has probably afforded more satisfaction to the shareholders than to the new undertakers.

Lead-Boring Insects.—The China and Japan Telephone Company, of Shanghai, China, has had an extraordinary experience in cable trouble, caused by the attack of an insect which pierced the lead covering of its telephone cables. It was noticed several years ago that the lead sheathing of the aerial cables was perforated by holes, which admitted water and gave rise to much trouble. It was assumed that the injury was caused by small rifle bullets, and a reward of 50 taels was offered for information

Digitized by Google

that would lead to the punishment of the wrongdoers. Later it was established that the holes were the work of wasps of a species that lays its eggs in the living bamboo. These wasps gather around bamboo groves in July and August to lay their eggs inside of the cane, where they will be well protected from attacks of hungry enemies. The cables were never attacked any distance away from bamboos. As immediate protection linseed oil boiled to the consistency of birdlime was used, and later all cables in the localities where damage had been done were covered with hemp cloth so as to present a soft surface which the insects do not attack. The *Electrical World* gives several illustrations of injured cables, which show that the insects made several attempts before they succeeded in biting through the sheathing.

Telephone Purchase.—Sir Henry H. Fowler, M.P., when presiding over the meeting of the National Telephone Company this last week, gave details of the progress of the undertaking. Speaking as to the negotiations with the Government, he said that under the company's license the Government had power to give notice on June 30 last of its desire to acquire the company's undertaking compulsorily on Dec. 31 next, the terms of purchase in the event of difference between them to be decided by arbitration. That notice had not been given, and consequently the compulsory rights had ceased, but the Postmaster-General had intimated his desire to come to an arrangement with the company by agreement, and negotiations with that object in view were now in active progress. The matter involved intricate calculations, and many difficult questions would have to be considered which could not be hurriedly determined. He believed that the Postmaster-General would credit the Board with the desire to meet him in a fair spirit, and he hoped that the negotiations would result in a satisfactory arrangement which would enable a great public service to be adequately and properly developed, and which at the same time would be one that was equitable and fair to the shareholders. The directors deprecated discussion, and asked that the shareholders would evince their confidence by leaving the negotiations in the hands of the Board.

Terrestrial Magnetism Researches.—The June issue of *Terrestrial Magnetism and Atmospheric Electricity* (Baltimore) gives a brief account of the work which has been planned for the department of international research and terrestrial magnetism of the Carnegie Institute for 1904. Besides the work of organisation of the department, the compilation, discussion, and preparation for publication of the data for the complete presentation of existing knowledge of the earth's secular magnetism over the entire globe, for the determination of the points at which it will be necessary to repeat observations at suitable intervals, for the successful scientific investigation and determination of the causes and their modes of action, and for ascertaining the proper corrections to magnetic charts, to refer them to a desired date, have been authorised and begun. These researches are a continuation of Dr. L. A. Bauer's studies. The department has been authorised also to take up the discussion and publication of the data on the magnetic perturbation observed during the eruption of Mont Pelée, Martinique, in 1902; further, the compilation, discussion, and publication of the existing data concerning the variation of the earth's magnetism other than the secular variation already provided for, and the perturbations of the earth's magnetism will be carried out. Authority has also been given to enable the department to make the necessary preparations for future observational work, and to take part in the observation of such of the earth's magnetic or electric phenomena of momentary occurrence as are of the highest importance to the advancement of our knowledge.

Society of Engineers.—A highly interesting visit was made by the president (Mr. D. B. Butler) and members of the Society of Engineers on Wednesday to the shipbuilding and engineering works of Messrs. Yarrow and Co. at Poplar, where they witnessed the building and engineering of light-draught high-speed craft of all kinds, notably torpedo-boats, destroyers, and light-draught gunboats. Electrical driving has been adopted in the works, the main motive power being supplied by three Bellis and Morcom compound condensing engines, which drive three Parker dynamos direct, each dynamo being capable of an output of 430 amperes at 210 volts. Steam is supplied by three Lancashire boilers. Over the boiler-house is a cast-iron tank in which is a Ledward evaporative condenser. The drainage from the main roofs is collected in the tank and is used for condensing purposes, an economy in the use of the town water thus being effected. Most of the machine tools in the various shops are of the latest pattern and are placed in groups, each line of shafting being driven by its own motor. The shafting is 3in. in diameter, and runs at 140 revolutions per minute. The larger machines, which are not continuously at work, are driven by independent motors. The shops are fitted throughout with electric travelling cranes made by Messrs. Adamson. The air-compressing machinery is also driven electrically, a very complete pneumatic system being laid down throughout the works.

United Engineering Building.—This new building for the engineering associations of New York, and for an engineering club, is to be the gift of Mr. Andrew Carnegie. The United Engineering Building will occupy land 125ft. front by 100ft. on West Thirty-ninth-street, while the club, with a frontage of 50ft. and a depth of 100ft., will face on Bryant Park and the new public library. The United Engineering Building, apart from quarters for the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, and the American Institute of Mining Engineers, as well as other societies enabled to participate in the accommodation, will have several fine auditoriums and a magnificent library. The club building will be about 11½ storeys high, with the usual accommodation of a club and some 60 or 70 bedrooms for members. The work of tearing down the old buildings and the construction of the new is to be pushed vigorously, and will begin forthwith. From the *Electrical World* we gather that competitive designs were asked for for each building from a limited number of architects. As a result the successful competitor for the United Engineering Building is Mr. Herbert D. Hale, of Boston, with Henry G. Morse, of New York, as associate architect. The successful competitors for the engineers' club are Whitfield and King, of New York, who have done a large amount of work in New York city and on some Carnegie libraries, and were also associated in work on the buildings of the Pan-American Exposition.

Electrostatic Motors.—Mr. Clark, the editor-in-chief of the *Polytechnic Engineer*, of Brooklyn, contributes to the 1903-4 issue an interesting article on electrostatic generators, which gives a brief historical sketch of these machines and the results of efficiency tests. The maximum voltage generated by the Holtz machine is not determined by the maximum speed of rotation of the plates but increases the distance between the discharge knobs. It is also dependent upon the location of the spark-gap with respect to the large stationary balls attached to the collecting combs. The Holtz machine is reversible in its action in the same sense as a dynamo-electric machine—that is to say, it will operate as a motor if supplied with

Digitized by Google

electricity from another influence machine. No previous excitation is requisite. The efficiencies of several machines were determined by operating one machine as a generator, and driving a second from this as a motor. The power input to the generator was determined by measuring the power supplied to the driving motor. The output of the static machine running as a motor was determined by means of a strap brake. The following are some of the efficiencies obtained: With a needle-point gap of 6in. the useful output of the generator was 71,200 volts; the current 0·000482 ampere, equal to 34 watts; the efficiency, 27·1 per cent. With a spark gap of 12in. the voltage was 122,000; the current, 0·000319 ampere; watts, 39; efficiency, 22·2 per cent With a gap of 18in. the voltage was 180,000; current, 0·000194; power, 35 watts; efficiency, 19·5 per cent.

Central Technical College.—At a meeting of the council of the City and Guilds of London Institute, held on Monday last, the diploma of "Associate of the City and Guilds Institute" was awarded to the following matriculated third-year students of the Central Technical College who have completed a full course of instruction as prescribed by the council: civil and mechanical engineering—H. D. Creedy (Siemens medal), J. M. de Artola Soruco, W. G. Banister, A. A. Barnes, G. A. Beggs, F. S. Bond, L. J. G. Bowers, S. Bowen, A. Carmichael, E. M. Cory, O. C. Daniell, J. A. V. Dupré, S. S. Elliott, T. G. Garforth, C. W. Gibbs, G. R. Griffin, H. R. Liebstein, N. N. Maas, F. Neuhaus, H. A. Newton, R. H. Osler, R. Peters, E. F. R. Pole, R. B. Robinson, W. S. Strachan, A. H. Street, O. H. Teulon, O. W. Thomas, S. M. Udale, A. E. M. Van der Meersch, R. F. Vogel, E. G. Walker, F. E. Walker, H. J. Wheaton, H. H. Wilder, J. W. Wooding; electrical engineering—H. W. Purle (Siemens medal and premium), A. M. Beale, A. Cunnington, C. H. Davidson, O. I. Davis, C. F. Edwin, E. Fisher, C. J. Guttmann, R. A. Harris, M. Hayashi, H. W. Kefford, W. C. C. Langdon, H. C. Lott, W. H. Lowe, C. B. R. Merton, C. J. C. Moon, A. R. Palmer, L. M. Rampal, L. I. Solomon, T. D. W. Weston, J. L. Wilson; chemistry—P. S. Arup, T. R. Lucas, Miss M. N. Reid, R. W. Tonkin. In addition to the above, certificates have been awarded to 32 matriculated third-year students who have completed a full course of instruction at the Central Technical College and to 61 students who have completed a full course of instruction at the Finsbury Technical College.

Hand and Mechanical Stoking.—At the recent convention of the National Electric Light Association at Boston, U.S.A., a paper, of which an abstract appears in the *Western Electrician* of Chicago, was read by Mr. Edwin Yawger dealing with the relative merits of the mechanical stoker and the human operator—a subject which came in for considerable discussion in connection with the paper presented to the Institution two or three months back by Messrs. Merz and McLellan on "Power Station Design." Mr. Yawger does not express a decided opinion on the superiority of one method or the other, though he is inclined to favour the automatic form, but comments on some of the features which distinguish them. He remarks that a universal result of the substitution of mechanical for manual methods is greater uniformity of product, and that from the nature of the operation it is possible to maintain an automatic stoker at or near its maximum efficiency. A point which the author emphasises is that the efficiency of the human operator varies in a very appreciable measure. Taking some comparative economy tests on traction engines which he conducted, the author states that he found a difference of 10 per cent. in the results even between expert firemen. Another matter to which he alludes is the variation in dranght with different furnaces where a number are connected to the same stack, and he remarks that all the losses attributable to improper manipulation of the air supply are magnified in the case of hand firing. The author considers that it is in its capability of yielding the maximum efficiency by responding to intelligent supervision that the mechanical stoker exhibits a superiority over its human rival.

Electrical Tanning.—An account is given in the *Electrical World* of New York of a tannery electric power equipment at Newark, N.J., where leather of the highest grades is manufactured. A plant of this sort must necessarily spread over a considerable area. When steam-driven, at least 40 per cent. of the power is required to set the belts and shafting in motion before the machines can do any work at all. In the transmission of power from generator to motor there is only a fraction of this loss, and it is no longer necessary to crowd buildings together for the purpose of saving power. Many of the processes require light, which is easy to supply when countershafts and belts are eliminated and electric lamps can be hung at convenient points. The electric power plant, which superseded the old steam plant, consists of two compound-wound 75-kw. Crocker-Wheeler generators of the direct-connected type, but arranged, with a central pulley, for belting. These are driven at a speed of 275 revolutions per minute by a Watts-Campbell 200-h.p. 18in. by 42in. steam-engine, with a 16ft. by 30in. flywheel at 75 revolutions per minute carrying the belt. The switchboard is built in three panels. The left-hand one supports a Walker Keystone ammeter, a Ward Leonard rheostat, an 800-ampere Cutter "I. T. E." circuit breaker, and an equalising switch for one of the generators. The right-hand panel is similarly equipped for the other generator. On the centre panel is a Walker Keystone voltmeter, 12 250-volt switches, six of 100 amperes, two of 200 amperes, two of 300 amperes, and two of 400 amperes rating. The 150-h.p. tubular boilers supply steam to the engine, and serve to maintain a high temperature in the japanning ovens. The boilers are for the most part stoked with damp bark that has been used for tanning, supplemented with soft coal. Exhaust steam is used to heat the buildings in winter and the hide-drying lofts all the year round. The whole time spent in producing a perfectly cured patent leather hide is about six weeks, as against as many months by the old methods, and there is probably no one factor which has contributed so much towards modernising the tanning process as the use of electric power.

Junior Institution of Engineers.—The members of this institution, through the courtesy of Messrs. Coode, Son, and Matthews (the engineers) and Messrs. S. Pearson and Son (the contractors), were recently afforded the opportunity for inspecting, under special facilities, the National Harbour works at Dover. Permission was also kindly given for the works of the Dover Harbour Board, of which Mr. A. T. Walmisley is the engineer, to be seen, and the turbine S.E. and C.R. Channel steamer, "The Queen." Subsequently the members were welcomed at the town hall by the Mayor and Mayoress of Dover (Sir William and Lady Crundal), and an organ recital was rendered there by the borough organist, Mr. H. J. Taylor. To all who had assisted in the arrangement of the interesting day's programme the chairman (Mr. S. Cutler, jun.) expressed the hearty acknowledgment of the institution whilst the members were assembled in the Council chamber. On arrival at Dover the party (about 100 in number) went aboard "The Queen," just previously to her starting for Calais, the chief interest, of course, being centred in the engine-room, containing Parsons turbines of 8,000 i.h.p.,

Digitized by Google

capable of propelling the vessel at 21·73 knots. From the Admiralty Pier the members were taken by a tug belonging to the Dover Harbour Board across to their Prince of Wales Pier, where the big Atlantic liners of the Hamburg-American line now call. This pier was built by Sir John Jackson, Limited, to the designs of Messrs. Coode, Son, and Matthews. The swingbridge on the connecting railway was shown in motion. After luncheon the Admiralty Harbour works were seen, the members being conveyed along the east arm by the contractors' railway. All the operations in the preparation of materials and in the processes of construction were explained in detail. Some of the party viewed the work from one of the Harbour Board's tugs. The total length of sheltering works is 9,520ft., and the area enclosed will be 610 acres at low water. All the under water work of the Admiralty Pier extension and of the east arm is practically completed, and a commencement has been made on the island breakwater, which is to be built in a similar manner by concrete blocks, the bedding of the first course being prepared by means of grabs and the use of diving bells.

Books Received.—The Western Society of Engineers have sent us from Chicago the third part of their ninth volume, giving their papers and discussions and also some abstracts. The particular features in this number are two papers on "Reinforced Concrete" and the discussion on the same. There is, however, an interesting communication on the hydro-electric power development at and near Joliet (Ill.), using Chicago drainage canal water, by Thos. T. Johnston, M.W.S.E. This installation is peculiar in many ways, as the power scheme makes use of the water from the Chicago drainage canal. The author describes the installation in detail and illustrates the power house. It is seen from the commercial troubles overcome that there was no little difficulty in getting the necessary agreements with conflicting authorities. The fifth volume of the *Transactions* of the American Electrochemical Society has just come to hand. It is quite up to the standard of its predecessors, and contains a large amount of original matter. The following extracts from the index of papers show what a wide range electrochemistry enjoys nowadays. Thus, these papers are: "The Continuous Advance of Electrochemistry" (Richards), "The Standard Cell" (Wolff), "Preparation of Materials for Standard Cells and their Construction" (Carhart and Hulett), "Single Potentials of the Halogen Elements" (Mott), "The Composition and Resolution of Voltages" (Richards), "Molecular Conductivity" (Reed), "The Economic Balance in Electrolytic Copper Refining" (Addicks), "Remarks on Prof. Jos. W. Richard's Theory of Heat of Neutralisation as presented to the Society, Sept. 19, 1903" (Westman), "The Energy of Ions" (Parsons), "The Aluminium Electrolytic Condenser" (Zimmerman), "A Contribution to the Study of the Electric Arc" (Weedon), "Some Phenomena Observed in Connection with the use of a Copper Voltameter" (Adams and McNutt), "Electrolytic Iron" (Burgess and Hambuechen), "Thermo-Electric Determinations of the Reduction Temperature of Zinc Oxide" (Johnson), "Exhibition of Porous Plates" (Sadtler), "An Index to Electrochemistry and its Application" (Voege), "Observations on the Preparation of Electrolytic White Lead" (Carrier), "Electric Smelting Experiments for the Manufacture of Ferro-Nickel from Pyrrholite" (Sjöstedt), "Dissociation by means of the Alternating Electric Current" (Davis), "Notes on the Industrial Electrolysis of Water" (Landis), "The Thermo-Chemistry of Electrolytic Dissociation" (Reed), "A Strange Observation" (Moltkehansen), "Exhibit of Ferro-Metals, made Electrically, and of other Electric Furnace Products" (Rossi).

The Inverted Repulsion Motor.—A recent issue of the *Electrical World* of New York contains an article on this subject by Mr. Karl Faber. The author states that the commutation of the inverted motor is inferior to that of the repulsion motor, due to the absence of the revolving field in the former machine. As far as concerns the commutation, the circuits of the inverted machine are similar to those of a compensated series motor, and experiments show that in neither the case of the inverted nor the repulsion motor is the sparking destructive, and the difference in the commutation of the two machines is inappreciable. As stated by the author, the inverted motor should be much lighter than the repulsion motor, and for traction service the former machine seems to be superior to the latter, which necessitates both a transformer and a motor located in the limited space available upon a car truck. The editorial comment of this article is as follows: Since the circuits of a repulsion motor are in many respects similar to those of a stationary transformer, it seems at first glance quite obvious that, if a proper value of impressed E.M.F. be used, the machine can be operated inverted—that is, with primary and secondary circuits interchanged. To one giving merely a passing thought to the subject, it might appear that the performance in the one case would be quite similar to that in the other; and since only a relatively low E.M.F. could be impressed upon the commutator, that a decided advantage would be gained by using as primary stator coils capable of being wound for any convenient E.M.F. A more careful study, however, reveals the fact that, when operated inverted, the repulsion motor develops distinctly different characteristics from those under normal conditions, and the difference in performance is attributable to the counter E.M.F. of rotation produced at the commutator. With the rotor stationary, the repulsion and the inverted motors show equal torques per kilovolt-ampere input and equal power factors, the motor windings in each case being those of a stationary transformer with secondary on short-circuit. With the inverted motor the counter E.M.F. of rotation produces an effect similar in all respects to the insertion of resistance in the primary circuit of the transformer, decreasing the current and the core magnetism and increasing the power factor indefinitely with increase of speed. With the repulsion motor the effect of the motion of the secondary is not only not to cause a decrease in core magnetism, but also to allow the magnetism to increase, and the exciting ampere-turns must, therefore, be increased. Since, however, the secondary current is caused to lead the primary E.M.F. in phase, the exciting ampere-turns need not be supplied wholly by primary current, and the effect of speed on the motor circuits is similar to the insertion of resistance and some condensance in the secondary circuit of the transformer. The repulsion motor is practically a constant magnetism machine, while the inverted motor is of the variable magnetism type.

Measurement of Insulation Resistance by means of an Electrostatic Voltmeter.—In an article which appeared in a recent issue of the *Elektrotechnische Zeitschrift*, Dr. J. Sahulka describes how insulation resistances of dead cables may be measured by means of an electrostatic voltmeter. It is requisite that the instrument should possess a range equal to the working potential; also that a resistance be provided of a value determined by that of the resistance to be measured. The accompanying diagram shows the arrangement for measuring the insulation resistance of a cable. As in the case of measurements by means of a direct deflection, one pole of the battery or dynamo is connected to earth, while the other pole is connected through a resistance, *w*, with the core of

Digitized by Google

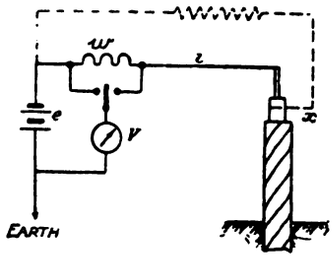
the cable. In order to prevent a leakage of current from the core into the cover of the cable, a guard wire may be employed as shown by the dotted line. The insulation resistance to be measured is represented by x. The electrostatic voltmeter, V, may be so connected by means of a switch that it measures either the potential, e, at the terminals of the testing battery, the potential at the resistance $(w+x)$, or the potential, e', at the insulation resistance, x. The resistance, w, must suffice to cause an appreciable loss of potential, so that $e' < e$. Since the same current, i, flows through the resistances, w and x, it follows that

$$w+x : x = e : e',$$

whence

$$x = \frac{w e'}{e - e'}.$$

In this case the measurement of the insulation resistance is effected similarly as the determination of a resistance by a comparison of the difference of potential on the same with that on a known resistance in series, except that a fraction only of the working potential is compared. For example, a very well insulated installation of house wiring for a



three-wire system (2 × 110 V.) was tested with the wires dead. The installation was connected through a suitable resistance box to one pole of a testing battery, whose second pole was earthed. The working potential was

$$e = 110{\cdot}8 \text{ V.}$$

Inserting resistance $w = 100{,}000\ \Omega$, the potential obtained at the insulation resistance was

$$e' = 101{\cdot}4 \text{ V.}$$

Hence

$$x = \frac{100\,000 \,.\, 101{\cdot}4}{110{\cdot}8 - 101\,4} = 1{,}072{,}000\ \Omega.$$

In the case of another installation on the three-wire system

$$e = 111{\cdot}0 \text{ V};$$
$$w = 11{,}000\ \Omega;$$
$$e' = 91{\cdot}7 \text{ V};$$

whence

$$x = 110{,}000\ \Omega.$$

Testing Live Mains for Insulation Resistance.—In a previous note we have referred to an article by Dr. J. Sahulka, in which the author describes how an electrostatic voltmeter may be employed for measuring the insulation resistance of dead cables. In the same article the author shows how insulation measurements may be made on continuous-current two-wire and three-wire networks, while alive, with the aid of a similar instrument. In the accompanying diagrams (Figs. 1 and 2) the separate conductors are marked L_1, L_2 . . . ., the fault resistance of the same to earth f_1, f_2 . . . ., and the leakage current flowing through these resistances in the direction of the conductors to earth, i_1, i_2 . . . The total insulation resistance of the network, x, is always given by the formula

$$\frac{1}{x} = \frac{1}{p_1} + \frac{1}{f_2} + \ldots .$$

The potentials existing between the individual conductors and earth, when no artificial resistances are inserted, are marked V_1, V_2 . . ., the values for the same depending entirely upon the resistances of the faults and the working potentials between the conductors. As a rule these are not equal, and may be represented by e_1, e_2, . . . The author goes on to describe how known methods of measuring the insulation resistance may be facilitated by using an

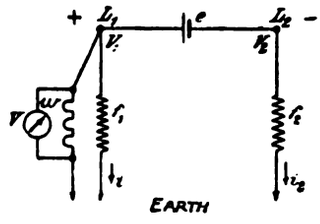


Fig. 1.

electrostatic voltmeter, V, with a resistance, w, in parallel, as shown. By connecting the voltmeter, without the resistance, between one of the conductors and earth, the difference of potential existing between the conductor and earth may be at once determined. We now connect a resistance, w, in parallel with the voltmeter of sufficient value to

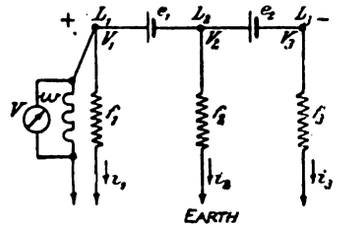

Fig. 2.

cause an appreciable reduction in the reading obtained. The measurement may be further simplified by employing the Frölich method, while using an electrostatic voltmeter instead of a galvanometer. But in measuring the insulation resistance of a multi-wire system the instrument must be connected between an outer and earth—not between the middle wire and earth. The Frölich method consists in connecting a galvanometer of high resistance, g, between a conductor—for instance, L_1—and earth. By switching in the galvanometer, the potential between the conductor and earth is varied. Let us suppose the reading obtained be V_1'. We now connect in parallel with the instrument a resistance, w, of such value that the deflection obtained is reduced to a value, V_1''. The insulation resistance, x, of the system may then be determined with the aid of the formula,

$$\frac{1}{x} = \frac{V_1''}{w\,(V_1' - V_1'')} - \frac{1}{g} \quad . \quad . \quad . \quad . \quad (a)$$

If we employ an electrostatic voltmeter, V, instead of the galvanometer, $g = \infty$. By connecting this voltmeter between the conductor, L_1, and earth, a direct reading is obtained of the potential, V_1, between the conductor and earth corresponding to the resistances of the faults alone. We now connect a resistance, w, in parallel with the voltmeter, so as to reduce the reading given by the instrument. If the value be V_1', then

$$\frac{1}{x} = \frac{V_1'}{w\,(V_1 - V_1')},$$

and therefore

$$x = w\left(\frac{V_1}{V_1'} - 1\right) \quad . \quad . \quad . \quad . \quad . \quad (b)$$

The advantage of employing an electrostatic voltmeter consists in that the formula (b) then serves instead of the more complicated formula (a). The author refers to a method explained in a previous article for determining the fault resistances of the individual conductors of a three or five wire system,

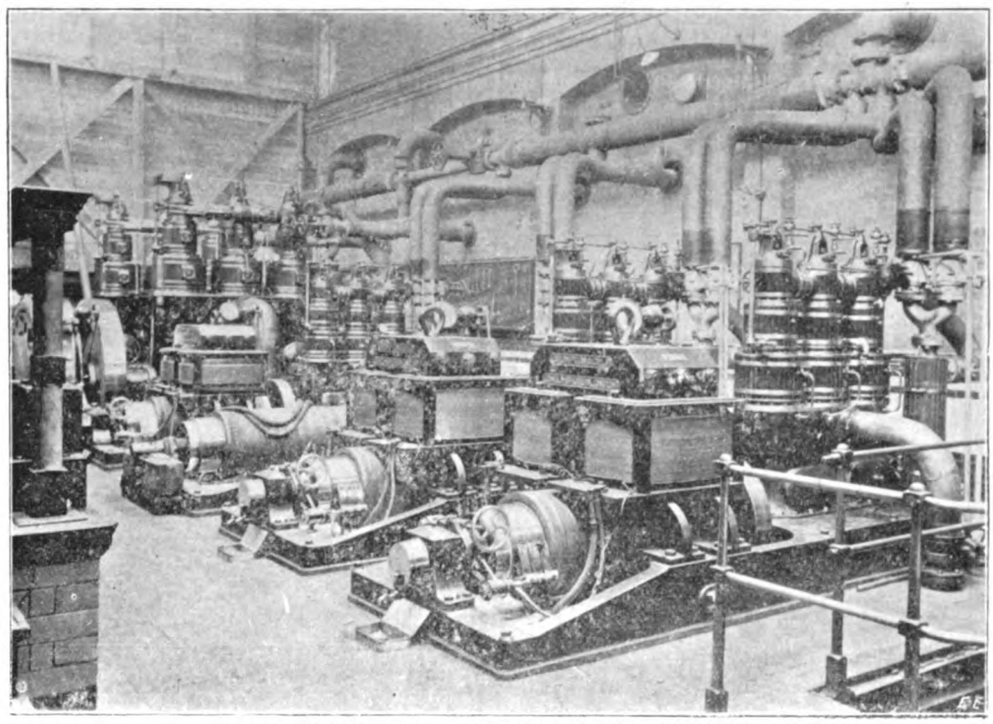
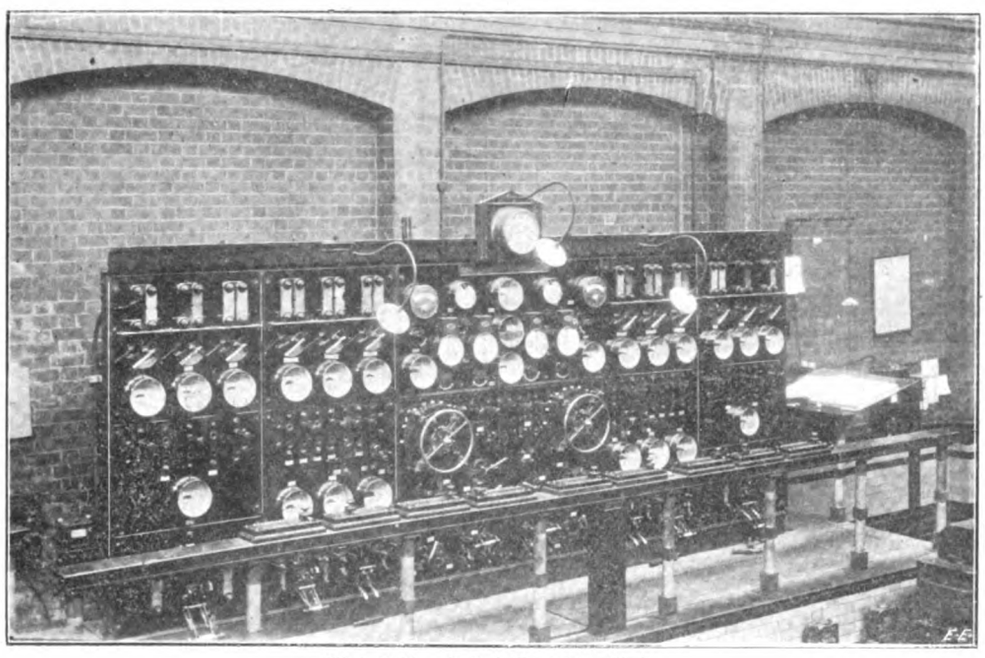
EXTENSION OF THE ELECTRIC LIGHTING STATION OF THE YORK CORPORATION ELECTRICITY DEPARTMENT.

Municipal trading in the ancient city of York is very limited, and it is, therefore, not surprising to find that a great deal of interest is taken in the first undertaking governed by the public body. When first the authorities unfolded their scheme for the supplying of electric light in the city, there were, as is usually the case, a certain section of the community who prophesied that the concern would serve to increase the rates, but although much opposition from this party has not aided the growth of the undertaking, it is being fully borne on the ratepayers that they have now in their possession a well-organised department, which, it is confidently anticipated, will in the near future prove to be a most valuable asset to the city. The growth of the undertaking has been phenomenal, as, although it was only inaugurated four years ago, the number of units generated during last year amounted to nearly a million, and it reflects great credit on the city electrical engineer, Mr. C. A. Midgley, seeing that the very low price of gas in York makes the local gas company a very formidable rival.

The ceremony which took place at the electricity works on Monday, the 18th inst., when the formal opening of the extensions was performed by Mrs. H. V. Scott (wife of Mr. Councillor H. V. Scott, chairman of the Electric Lighting Committee of the York Corporation), is the result of the greatly increasing demand on the station. On this occasion there were also present the members and officials of the Corporation, representatives of the contractors engaged on the extensions, and a large number of the prominent citizens and principal consumers.



Interior of Engine Room—Old Portion—York Electricity Works.



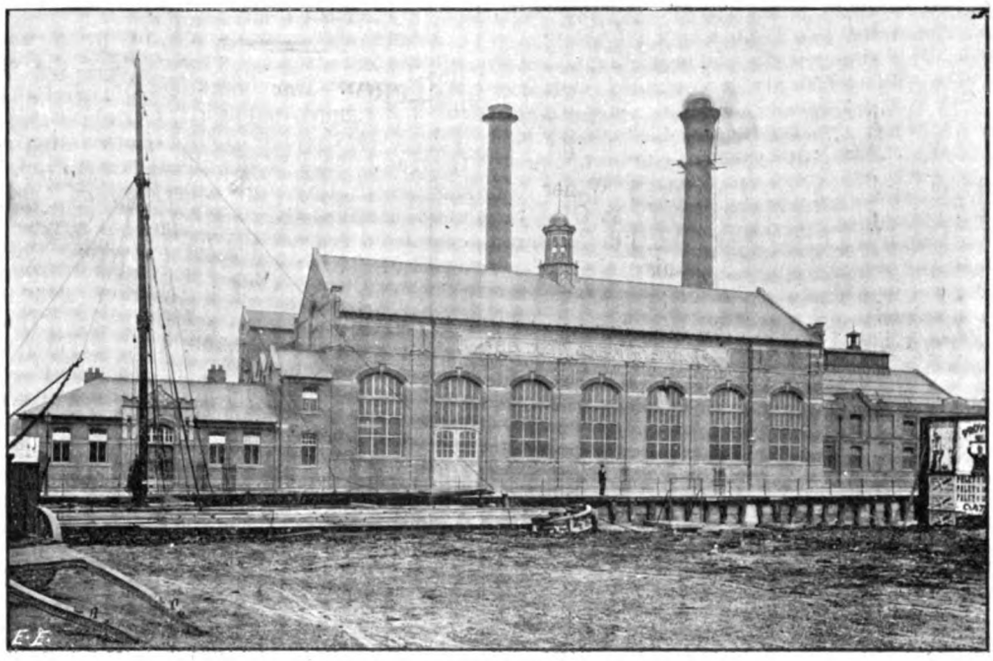
Old Switchboard, York Electricity Works.

Mrs. H. V. Scott having been presented by the building contractors (Messrs. Arnold and Son, of Doncaster) with a handsome gold key, on the handle of which was engraved the city arms, unlocked the door and the company entered the building. Mr. Councillor H. V. Scott then addressed the assembly from a large platform in the new building, and, after welcoming them on behalf of the Electric Lighting

Digitized by Google

Committee, gave a brief history of the undertaking. The works were opened on April 2, 1900, and the initial instalment of generating plant put down was capable of supplying some 6,500 lamps; but, owing to the large demand, additional plant had to be installed, and the generating capacity was increased to 13,800 lamps By the winter of 1900-1 a further extension had to be carried out, and in March, 1902, the capacity of the station had increased to 24,000 lamps (1,200 h.p.). At that time it was fully

The plant in the new engine-room consists of two Willans and Robinson's high-speed engines of the vertical compound type, developing 850 h.p. when running at full load, and they are each coupled direct to a 520-kw. dynamo of the continuous-current shunt-wound type, of Messrs. Dick, Kerr, and Co.'s manufacture. Messrs. Allen and Sons have supplied a surface condenser which is capable of condensing 30,000lb. of exhaust steam per hour, and the motors used in connection with the condenser are of the enclosed

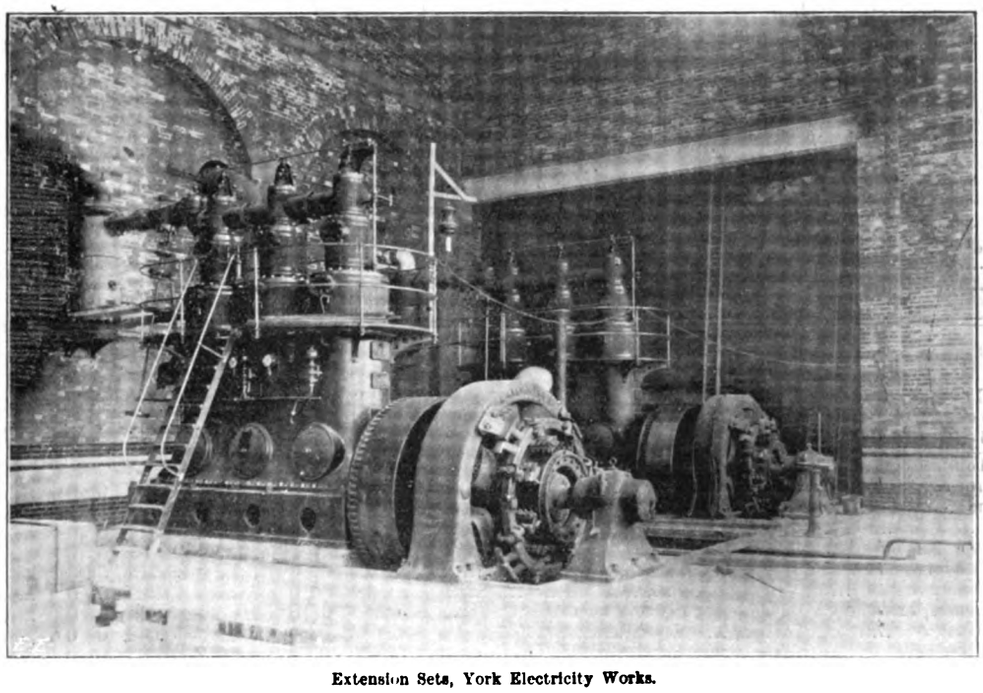


Engine Room Extension, York Electricity Works.

recognised that, owing to the great demand for energy, a further large extension would have to be made, and in October, 1901, the Council resolved to extend their buildings on a large scale. The completion of this extension was marked by the opening ceremony on Monday last.

The extensions have been carried out to the designs of the city electrical engineer (Mr. C. A Midgley), and the

shunt-wound type, and have been supplied by Messrs. Dick, Kerr, and Co., who have also supplied the switchboard for same. A 20-ton hand travelling crane, by Messrs. Higginbottom and Mannock, of Manchester, runs the full length of the engine-room, and the stone blocks on which the rails for the crane are fixed are fitted with hand-rails; a platform running along both sides of the building has thus



Extension Sets, York Electricity Works.

city surveyor (Mr. A. Creer) is responsible for the structural alterations. To the old engine-room, which was 68ft. long by 32ft. wide, has been added a lofty, well-lighted room, 122ft. long, 47ft. wide, with a height of 36ft. to the eaves, adjoining which are offices for the city electrical engineer, assistant engineers, and clerks, also well-equipped testing, motor, and meter rooms, stores, etc., have been provided.

been made at a very small extra cost. The switchboard, which is of white marble, is on a platform at the end of the room, 13ft. above floor level, and is so arranged that a complete view of the old engine-room, as well as the new room, can be obtained. Accommodation has been made for further extensions of plant, foundations having been built for two sets of 1,000 h.p. each, and one set of

Digitized by Google

2,000 h.p.; the necessary condensing chambers have also been constructed.

In the new boiler-house are three Babcock and Wilcox boilers of 1,000 h.p. each when working at 130lb. steam pressure. They have each a grate surface of 4,872 square feet, and are capable of evaporating 15,000lb. of water per hour. They are fitted with Babcock and Wilcox chain-grate stokers and superheaters. The superheaters are capable of adding 80deg. to 100deg. F. to the temperature of the steam at the engine stop valves. The boiler-house is divided into two banks of four each by the pump-room, which at present contains two Weir steam pumps of the vertical double-acting type, which are so arranged as to allow of them being worked singly or in parallel, and they are designed to lift and deliver to the boilers, against 130lb. of steam, 2,500 gallons of water per hour. Above this room is a large cast-iron tank, 18ft. square by 6ft. deep, and the plates of the tank are $\frac{5}{8}$in. thick. When full, the tank holds 75 tons of water. The water used at the works is obtained from the River Foss, which flows alongside, but in case the supply from this source should fail, the town's water can be utilised, a special main having been brought into the works.

All the pipework has been supplied and erected by Messrs. Dick, Kerr, and Co, and the lagging of the boilers and steam-pipes has been carried out by Messrs. Hickson's, Limited, of Bradford. Between the engine room and the boiler-house is a steel chimney by Messrs. Head, Wrightson, and Co., of Thornaby-on-Tees, 116ft. high from the ground level, and lined to within 50ft. of the top with firebricks. The induced-draught arrangement in connection with the chimney has been carried out by Messrs. Davidson and Co., Limited, of Belfast. A further economiser of 480 tubes, which are arranged in four groups of 120 tubes each, has been installed. This work was carried out by Messrs. Ed. Green and Sons, Wakefield.

The supply of coal for the boilers will be brought along the Corporation's rails from the railway company's siding to the coal store, and will then be conveyed by the coal conveyor and elevator direct to the stokers. Messrs. Gibbons Bros. and Co., of Dudley, are now engaged on this work, and when this is completed, the whole of the work in connection with the extensions will have been carried out, and the station will be within reasonable bounds of meeting the demand, and the Corporation may well claim to be the happy possessors of a thoroughly modern and well-equipped electric generating station.

TELEPHONY AT GLASGOW.

Before these words are in print we hope to have another opportunity of inspecting the telephone system at Glasgow. Our immediate object, however, is to refer to the recently-published report of the Committee on Telephone Service to the Corporation of the City of Glasgow. This is the third report, and, considering the criticisms hitherto levelled against the work, deserves most careful consideration. It deals with the second completed year of the undertaking, and gives the position as at May 31, 1904. The total borrowing powers authorised now permitted a total of £350,000, as against £300,000, the extent last year. The total capital expenditure is £320,782. 12s., an increase of £50,050. 8s. 4d. during the year, and what the Corporation gets for this expenditure is shown in the accompanying Table A.

With the report is a summary of noteworthy points, which to a certain extent forms a reply to the many adverse criticisms against the undertaking. Why it is thought necessary to emphasise the points in the report is difficult to say; they speak for themselves. Nothing succeeds like success, and Glasgow telephony is successful. The revenue increased from £35,014. 2s. 9½d. to £49,639. 1s. 2d.; the balance to net revenue from £14,143. 0s. 7½d. to £20,519. 18s. 2½d. Why will accountants bother about this halfpenny? The net revenue has to provide interest and sinking fund. Anything remaining beyond the sum of these can be dealt with as the authority pleases. In Glasgow the balances have been appropriated to a general depreciation fund. The interest requires £8,537. 9s. 8d., sinking fund takes £8,343. 6s. 8d., leaving a balance for

TABLE A.

Work.	Original scheme.	Actually completed 1901-02.	1902-03.	1903-04.
Completed instruments	5,250	5,479	9,122	11,405
Partially completed lines	1,200	8,787	7,387	9,065
Switchboard accommodation	6,050 lines	7,060 lines	10,826 lines	12,062 lines
Pairs of cable wires	6,450	14,572	18,171	21,874
Mileage of pairs of wires in cables	4,938 miles	11,061 miles	14,029¼ miles	17,597 miles

general depreciation or general purposes of £3,650. 17s. 10½d., there being to credit of net revenue in addition to the above balance a sum received for interest of £11. 16s. The accompanying statistics relating to the undertaking will be interesting (see Table B).

These figures will want a lot of disputing, and till they are shown altogether incorrect we must congratulate Glasgow and its engineer with having successfully proved in the concrete what was academically argued to be impossible. When the successful man is told he does not know his business, he can afford to laugh.

THE WESTINGHOUSE UNIT-SWITCH SYSTEM OF MULTIPLE-UNIT TRAIN CONTROL.

(*Contributed.*)

It is now acknowledged by all classes of engineers that electricity offers the only satisfactory solution of the problem of the quicker working of city and suburban railway traffic, and there is no doubt that we are on the eve of a general, though necessarily gradual, conversion of local lines from steam to electric working. The chief reasons for this are two in number—firstly, the possibility of quickly building up or splitting up trains with one or more motor-cars combined with trailer or non-motor cars just as the density of the traffic requires; secondly, the high rate of acceleration which is obtained by having a number of pairs of driving wheels distributed along the length of the train. Each motor coach may be looked upon as a combination of an electric locomotive and a passenger car, but the driver's portion of such a car occupies so little space as to be almost unnoticeable, the motors, controlling gear, and brake gear being conveniently stowed away beneath the car body. As already mentioned, a car may be built up of one or more such driving units interspersed with trailers or non-motor coaches, this constituting the multiple-unit system of electric train working. One has only to consider the time occupied in getting up speed and in slowing down, say, on a run through a dozen city or suburban stations in order to appreciate the vital importance of rapid acceleration and retardation. That rapid acceleration can be obtained much more easily through the distribution of the driving power over many wheels (which is made possible by an efficient and reliable multiple-unit system) than through the usual concentration of the driving power in a steam locomotive, must be clear to anyone.

In this article we shall deal not so much with the multiple-unit train as with the method of *controlling* the driving power, as exemplified in the Westinghouse multiple-unit train-control system, which is the result of several years' experience of electric railway work. As evidence that this system of electric train control fully meets the requirements of up-to-date practice, it is only necessary to mention that among the railways which have already adopted it are the following: the Brooklyn Heights Railway, 514 sets of motors and controlling gear; the West Side Elevated Railway of Chicago, 156 sets; the Metropolitan Railway, Paris, 102 sets; and the entire contract for the Metropolitan Railway, London. These contracts alone aggregate, together with the Mersey Railway, some 1,364 motors, with a total of nearly 210,000 h.p. The following descriptions and illustrations refer more particularly to the apparatus with which the cars of the Metropolitan Railway of London are being equipped. The Westinghouse system has proved highly successful in the United States, and is also in satisfactory operation on the Mersey Railway in this country, which, it will be remembered, was converted to electrical working by the British Westinghouse Company.

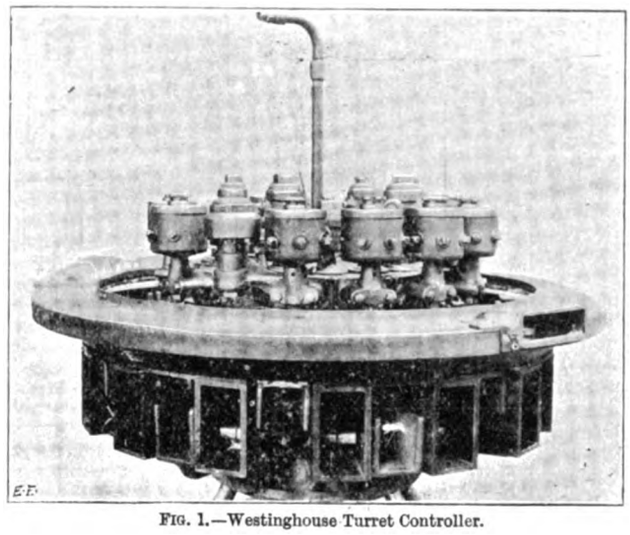

FIG. 1.—Westinghouse Turret Controller.

For large and heavy cars requiring very powerful motors, the latest and best form of controller is the Westinghouse turret controller. This takes its name from the fact that it is turret shaped. It consists of a number of radially-grouped circuit breakers or unit switches, which are closed by air pistons working against powerful springs, which open the switch contacts when the air pressure is removed. Fig. 1 shows a turret controller with its cover removed, and Fig. 2 illustrates its position on the underside of a motor coach. The 15 separate circuit breakers or "unit switches" which are employed are secured to a circular base, and are provided with a common magnetic blow-out coil at the centre. This single blow-out coil is a special feature, as it secures the ideal condition of maximum blow-out effect with minimum weight and space, and the number of parts and the amount of wiring necessary is very much reduced. Further, the use of a single coil enables it to be made of greater magnetic strength than could be the case if a number of smaller coils were used—one to each switch. The air pistons actuating the radial switches work in vertical cylinders, and the air admission is controlled by needle valves operated by iron-clad electromagnets, which,

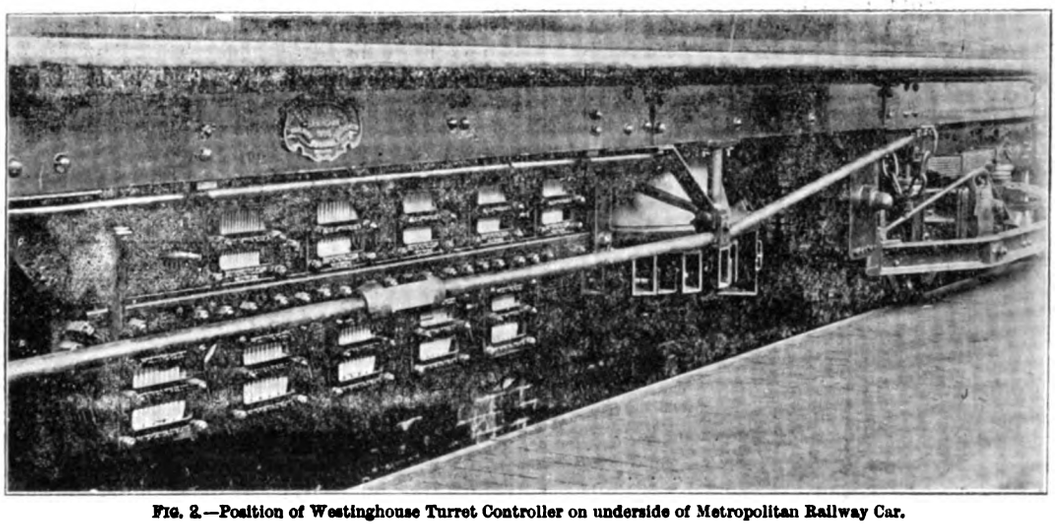

FIG. 2.—Position of Westinghouse Turret Controller on underside of Metropolitan Railway Car.

Digitized by Google

together with the cylinders, project above the main base casting of the turret, as seen in Fig. 1. A single pipe connection supplies compressed air to a central reservoir chamber, and ports around the latter admit air to the various magnetic valves, and thence to the cylinders, this construction reducing the amount of air-piping and joints to a minimum.

down from the main casting, and supports the spider and also the attachment for the bottom cover. It may be mentioned that the general arrangement of parts has been somewhat modified since Fig. 3 was drawn, but the latter is near enough for the purposes of a general description. The contents of each switch are enclosed in a vulcabeston box or arc shield (Fig. 1), and the magnetic lines from one

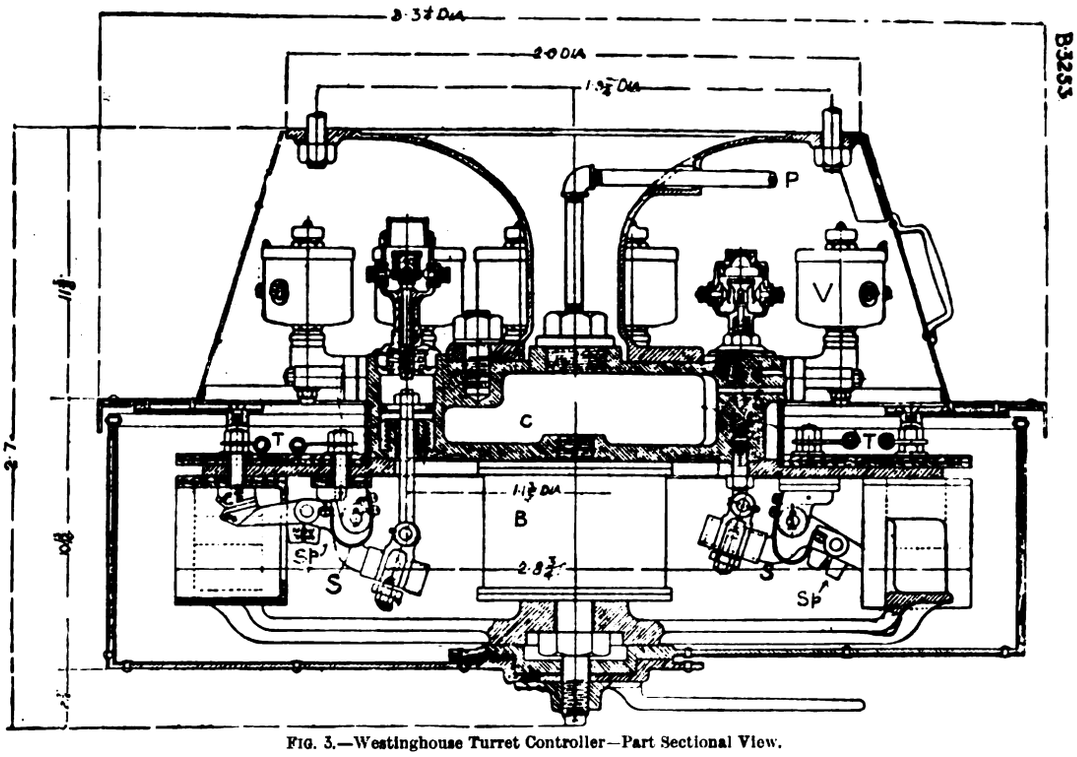

FIG. 3.—Westinghouse Turret Controller—Part Sectional View.

A view of the turret controller partly in section is given in Fig. 3. Here P is the compressed-air supply pipe, C the air reservoir, p the port leading to the magnetically-operated valve, V, and p' the port leading from the valve to the cylinder operating the switch, S, which is shown in the open position. Another of the switches, S', is shown closed,

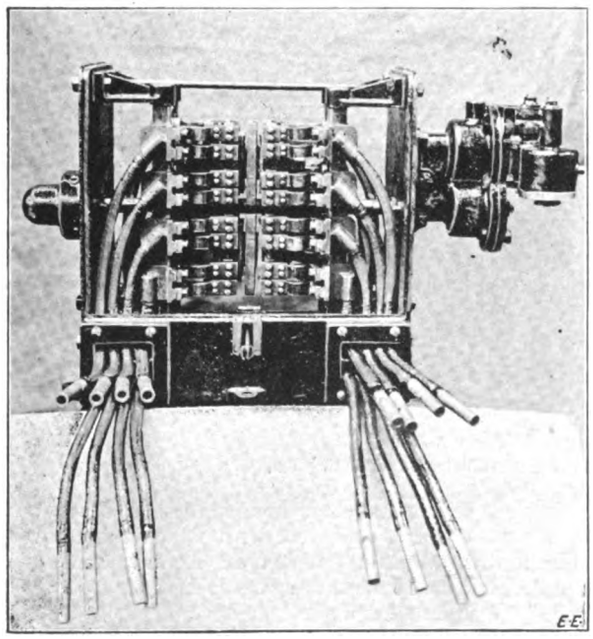

FIG. 4.—Westinghouse Unit-Switch System of Multiple-Unit Control. (Interior of Pneumatically-Operated Reversing Switch.)

and a section of the cylinder and piston operating it is given. B is the large blow-out coil, and two of the iron pole-pieces emanating therefrom may be seen to the right and left of the figure. These pole-pieces, which are more clearly shown in Fig. 1, are U-shaped, and point alternately up and down; the top ones being bolted to the main iron casting, and the bottom ones to the extremities of a cast-iron spider. The core of the magnet is fixed to and hangs

top and one bottom pole pass through each such box in a direction normal to that of the line of break of the switch—that is to say, horizontally. The strength of the blow-out field is such that test currents up to 18,000 amperes have been repeatedly and successfully broken, the burning at the switch contacts being negligible.

There is, of course, no limit to the length of break or the power of cylinder that may be employed when switches are operated pneumatically. Each switch is closed by the action of the air pressure in its cylinder, a powerful helical spring behind the piston being compressed at the same time. When the switch contacts are brought together, and also when they are separated, a spring in the moving arms

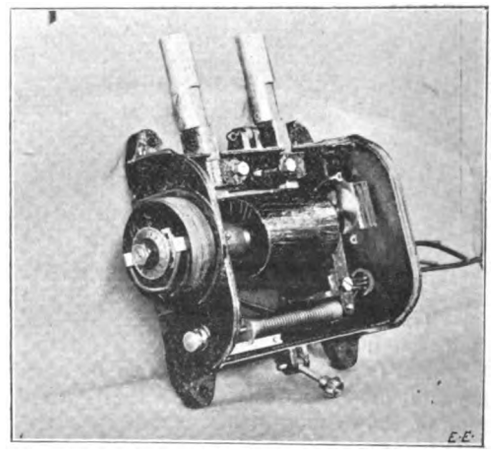

FIG. 5.—Overload and No-Voltage Return Relay used in the Westinghouse Unit-Switch Multiple-Control System (case open).

comes into play and brings about a rolling and sliding motion of the contacts, and so keeps their surfaces in good condition and prevents all tendency to burn or weld. This spring is shown at $s\,p$ in Fig. 3. Copper shunts are provided for all working pins and bushings in the switches, and the contact plates—which are easily renewable—are of ample area. When the exhaust port of the cylinder is opened, the spring under the piston drives the latter up and

Digitized by Google

opens the switch. The switch terminals are shown at T T in Fig. 3, both these and the switch parts being insulated from the circular base-plate of the controller by sheets and bushings of vulcabeston. It is a good point that the terminals are on the opposite side of the base to the switches, the cables being thereby divided off from the latter. Another good point is that the low-tension circuit terminals on the magnet valves are well separated from the comparatively high-tension switch terminals. The magnets

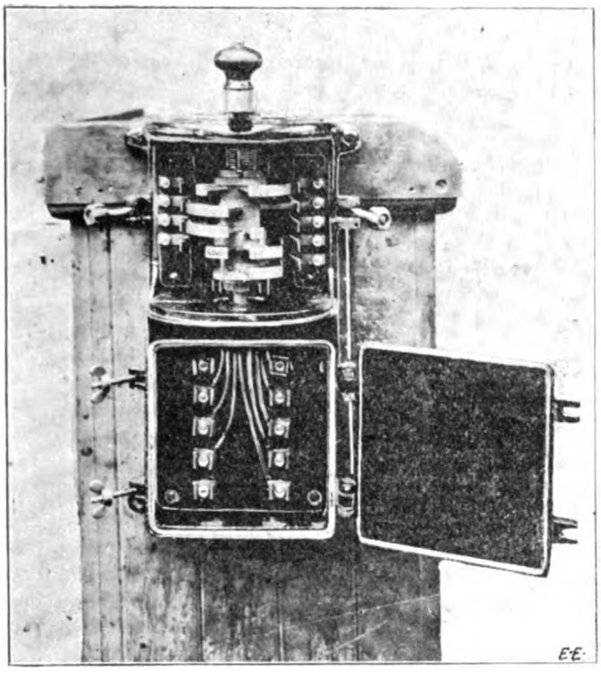

FIG. 6.—Master Controller used in the Westinghouse Unit-Switch Multiple-Control System.

and valves are enclosed by a hinged truncated cone-shaped cover, which can easily be removed, and the switches are enclosed by a revolving cover, the halves of which slide or telescope within each other.

In addition to the turret controller just described, a complete motor coach equipment includes a reverser, an automatic excess-current and no-voltage return relay, one or more small master controllers, and a switchboard for the controlling of the car-lighting, compressor, and battery circuits, this switchboard being depicted in Fig. 7. The reverser, which governs the direction of current through the motors, and, consequently, the direction of motion of the car, is operated by an air motor, the admission of air being controlled by electromagnetically-operated valves, similar to those on the turret controller, and is of substantial and simple design. Fig. 4 shows its construction. The overload and no-voltage return relay, which is shown in Fig. 5, is connected with the operating magnet of one of the cylinders in the turret, this cylinder actuating the switch which acts as main circuit breaker. The no-voltage part of this relay, which is mounted on the end of the case, no-voltage device acts, it causes the controller to go back to a point with high resistance in circuit, the latter then gradually and automatically "notching out" the resistances as soon as the supply is resumed. It should be noted that the no-voltage action of the relay is not so instantaneous as

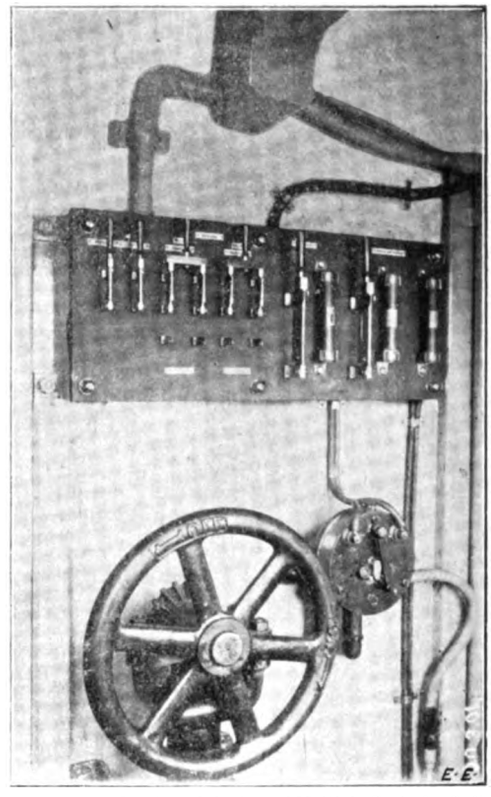

FIG. 7.—Westinghouse Unit-Switch System of Multiple Control.—Switchboard for Car Lighting, Air Compressor, and Battery Circuits.

to take notice of instantaneous interruptions due to the car contact shoe passing over points or crossings, and also that it does not act when the supply is suddenly cut off and

FIG. 8.—Westinghouse Multiple-Control System.—Low-Tension Circuit Connectors.

then suddenly comes on again; hence the term no-voltage return relay.

The connecting link between the electric and pneumatic gear and the human agent—the driver—now claims our

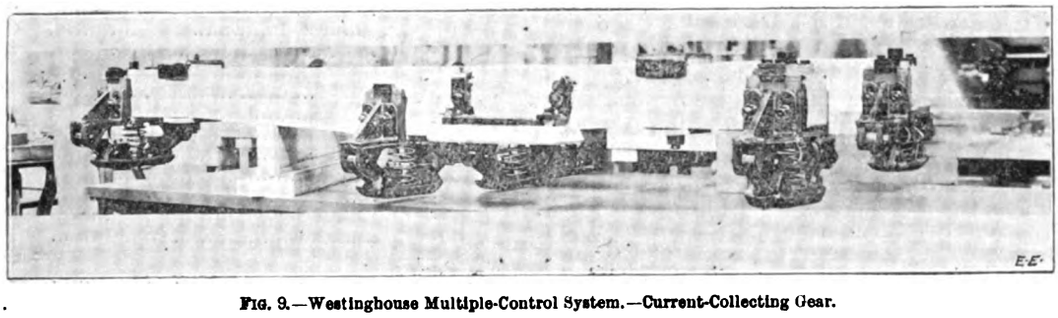

FIG. 9.—Westinghouse Multiple-Control System.—Current-Collecting Gear.

is of considerable importance, its function being to prevent the sudden restoration of full voltage to the motors and consequent flashing thereat, after any unforeseen interruption in the supply of power due to a break in the third rail, something going wrong with the contact shoes, a momentary interruption of the supply to the line, etc. When this attention. This—the master controller—is wonderfully compact, as will be seen by the accompanying illustration. Fig. 6 shows it in elevation, temporarily bolted to the side of a bench, and with its top and bottom casings opened out. The small size and light weight of the master controller, which is so called because it governs the

Digitized by Google

operation of the turret controller, is due to the fact that the currents operating the valve magnets of the latter are very small, and as they are derived from a low-voltage (seven-cell) storage battery, there is no necessity for arc shields or blow-out coils. The master controller has five notches for forward running and five for backward running, in addition to the neutral point. At the first "forward" notch, the emergency brake valve is set. At the second, the main supply circuit is closed and the reverse set. At the third—known as the shunting notch—the motors are connected in series with all resistances in. At the fourth, an automatic acceleration device comes into action, and the controller goes on notching up, provided it is not checked by the limit switch, till the eighth and last series notch is reached, the limit switch coming into play in order to maintain a uniform accelerating current. As the master controller drum is rotated, the pistons in the turret are actuated in due order, and the corresponding switches are closed. When the master controller handle reaches its last notch, the turret switches which have already been put on are simultaneously opened, and a number of others simultaneously closed, this making the parallel connections for the motors. Then, subject to the action of the limit switch, the controller automatically notches up to full parallel, and the highest speed point is reached. It is of special importance to note that should the driver throw his handle over to full parallel at the start, the controller will still work automatically and gradually through all the series and parallel positions, so that no harm can come to the motors. A further advantage of this automatic acceleration is that it ensures the utmost economy in power consumption. Thus, with non-automatic control, it has been found that from 10 to 15 per cent. more energy is consumed.

An ingenious safeguard is provided in case the motorman should lose his hold of the controller handle through inadvertence, accident, or sudden illness. The handle, when released, flies back to its neutral position by spring action, and in so doing interrupts a circuit through the magnets above the air-pipe. The effect of this is to open a valve and allow the air in the main pipe of the air-brake system to escape, with the result that the brakes are applied immediately throughout the train. When the brakes are not required to act, however, as in reversing, their above-mentioned automatic application may be prevented by passing the controller handle rapidly over the neutral notch. In running backwards, the operation of the controller is similar to its operation with forward running.

The motor coaches that are being equipped for the Metropolitan Railway (London) will be fitted with four 150-h.p. motors—*i.e.*, 600 h.p. in all—and each coach will weigh approximately 39 tons. The full-length train will consist of two motor and four trailer coaches; and it will be possible to split it up into five, four, three, two, or single coach trains as the density of the traffic decreases. The unusual power of these equipments is the reason for the large number of resistance steps in the controller, there being eight series and eight parallel positions. Nevertheless, the weight of the turret resistance, reverser, and pneumatic controlling gear is less than that of an ordinary electromagnetic control equipment. The cables are encased in asbestos slate mouldings, so that the fire risk is practically negligible. Fig. 8 depicts the nine-way low-tension controlling circuit sockets and plugs, which constitute the only electrical connection between neighbouring cars.

Fig. 9 gives a side view of the collector gear for one car. The two outer beams are fixed one each end of the car, and are provided with a positive collecting shoe at each extremity and a negative shoe in the middle. The shorter middle beam is placed at the centre of the car length, and carries a negative or return-current shoe only. The necessity for having collector shoes at each side of the car is explained by the fact that the conductor rail is sometimes on one side of the track and sometimes on the other.

Swinton.—In reference to the negotiations which have been proceeding between the District Council and the promoters of the proposed electric tramway, an interview was held a few days ago between the parties, when the company asked the Council to abandon the proposal that the town be lighted by electricity, offering as an inducement for this concession an annual rental of £100 or a payment of £1,000. The Council declined the offer.

THE RAWORTH REGENERATIVE CONTROL FOR TRAMWAY MOTORS.

On Wednesday last a demonstration was given at Gravesend both of the Raworth regenerative control for electric tram motors and also of the Demi-car on which the same was used. The trials were made on the lines of the Gravesend and Northfleet Electric Tramway Company, and the chairman of this company, Mr. W. G. Bond, was present throughout the trials. The Raworth generative control consists essentially of the use of shunt-wound motors on the tramcar instead of motors of the series type. This is not a new feature, but Mr. Raworth has carefully worked out the details and obtained successful regenerative results. For the convenience of those witnessing the trials, instruments were placed on the cars in order that the current taken from or returned to the trolley could be noted. There was also in the circuit a Vulcan electricity meter which measured the total draft of energy from the trolley wire. The armature of this meter revolved in the backward or negative direction whenever the car was returning energy to the line. In order to find out what percentage of the energy taken was returned, we counted throughout the return journey the revolutions of the brake disc of the meter in each direction. On the outward journey we also took the revolutions of the meter in each direction when descending the steep grade on Stone Bridge-hill to Plough Ponds It was then found that the car took electrical energy equivalent to 1½ revolutions of the meter when starting, and that on the hill it returned the equivalent of 22½ revolutions. The net return was, therefore, 21 revolutions. On the other journey this hill had to be ascended, and, as is shown in the following figures, the car took electrical energy for which the meter recorded 59 revolutions. In other words, in descending the hill this Demi-car, holding 20 passengers, returned 35·75 per cent. of the energy which it took when ascending the hill. The figures for the whole of the return journey are as follows:

TABLE I.

Return Journey from George and Dragon to Plough Pond, mostly down grade (about ¾ mile). Revolutions of meter representing energy taken from and returned to trolley wire.

28·3 per cent. of energy taken is returned by the regenerative motors.

From this it is seen that on the whole of the return journey of about three miles, 28·3 per cent. of the energy drawn from the line was returned by means of the regenerative control. These figures, which were taken by us quite independently of anyone interested in the undertaking, show that Mr.

Digitized by Google

Raworth has succeeded in his attempt to return to the mains a very considerable proportion of the energy which is usually wasted at the brake blocks or wheels of a tramcar in descending hills or in stopping the car to pick up passengers. The figures given us by Mr. Raworth are as follows. He stated that the Demi-car at Gravesend took on the average 0·380 per unit per car mile. The car weighs 5·6 tons, and carries 20 passengers. It is equipped with two Brush motors rated at 28 h.p. each.

As compared with this, the large cars now in use weigh 9·11 tons and carry 48 passengers. They are equipped with two Walker motors rated at 25 h.p., and consume 0 97 unit per car mile. In order to make these figures comparable, it is necessary to calculate how much energy the Raworth car would take if its weight and carrying capacity were the same as the larger car. Assuming that the energy taken goes up in proportion to the weight, the energy consumed would increase from 0·38 to 0·62. This latter figure is 64 per cent. of the energy consumed by the larger car, or it shows a saving of 36 per cent. for the regenerative control. These figures are most interesting, but before we give the advantageous points to be noted with respect to this system of control, we think it only fair to draw our readers' attention to the following. In the first place, the shunt-wound motors on these cars are always in use, either receiving current from the line or returning current to it. In consequence, they have to be considerably larger than those required on the series-parallel system. Thus at Gravesend the small car has two motors of 28 h.p. each, while the larger car, carrying 48 passengers as against 20, can be worked on the series-parallel system with two motors of 25 h.p. each. This increase of size, of course, only affects the first cost of the car, and the saving in electrical energy more than justifies the increased cost of the larger motors. Another question at issue is as to the cost of upkeep of shunt motors on tramcars used, as they have to be used, under regenerative conditions. These conditions are much more unfavourable as regards the commutator troubles than with series-wound motors. We trust, however, that by good design this difficulty will be overcome. There is one point yet to be considered, and that is the acceleration obtained from the shunt motors. Any comparative figures in which exactly similar conditions as regards acceleration are not obtained are open to criticism. In the trials on Wednesday last we had not to stop in order to pick up passengers, and we kept on the routes occupied by cars with series-parallel control without interfering with the traffic. From rough observations of the time taken to go the distance between two tramway poles, when starting from rest, the acceleration was about the same as on cars equipped with series motors, but the motors were larger for the work to be done.

The points to which our attention was especially drawn by Mr. Raworth are the following:

1. The Demi-car with regenerative control uses less than half the energy per car mile than the ordinary cars with series-parallel control. (N.B.—We make the figure 64 per cent. from results given for equal weight of car and carrying capacity.)
2. The driver can control the car with one finger.
3. The car can run up to facing points at full speed until the buffer is over the points.
4. The brakes are never used except on an incline to hold the car after retardation.
5. There are three definite braking effects: (*a*) regenerative, which will reduce the speed to four miles an hour; (*b*) the ordinary braking stop, which reduces the speed to about 1½ miles an hour; (*c*) the emergency stop, which pulls the speed up to half a mile an hour.
6. Sand is seldom required, because the adhesion is not overtaxed.
7. The maximum call on the power station is reduced by 40 per cent.
8. The maximum speed of the car can be fixed in the depôt. The driver cannot possibly exceed this speed, even on a descending grade.
9. The controller is extremely simple, and is sparkless if properly worked—*i.e.*, without hesitation.
10. There is no advantage gained by shutting off power at section insulators. The car lamps remain bright.
11. Every power position of the controller handle is also a braking position on a down grade or on a level by retiring the lever one notch.
12. The act of shutting off the power applies the brake, and the braking effect is continuous throughout the movement.
13. The motors are in series, and remain so. They might equally well be in parallel, but the windings would have to be finer and more expensive.
14. The power circuit is never shut off until it is necessary to stop. In the meantime the car can take power, can coast or regenerate as the road requires.
15. The feeder losses are reduced by one-half, and the size of the power station by one-third.

ON SINGLE-PHASE COMMUTATING MOTORS.*

If an ordinary direct-current series motor with laminated magnets is supplied with an alternating single-phase current, it would very soon become evident that it is not suitable for working under these conditions. The direct-current motor, in fact, belongs to a particular class of machines which may be called high magnetic resistance machines, in which it is the rule to make the exciting ampere-turns considerably greater than the armature ampere-turns. To this class belong the ordinary direct-current machine and the synchronous alternate-current machine. A second class is formed by the single and polyphase induction motors. In such machines the excitation of the field only requires from one-third to one-fifth of the full load armature ampere-turns. Machines of the first class are known to work better the greater their magnetic resistance is made, whilst the ideal machine of the second class is the one with the smallest possible magnetic resistance.

All workable alternate-current motors necessarily belong to the second class, as it is only by keeping the magnetic resistance low, and consequently reducing the field-turns, that a reasonable power factor can be obtained. In order to obtain a given torque with a weak field, a powerful armature must be employed having more ampere-turns than usual. These ampere-turns must, however, be prevented from interfering with the magnetic circuit, as any flux set up by them simply acts as harmful self-induction. The two requirements of a low magnetic resistance and a powerful armature which shall not produce a harmful field are contradictory, and investigators soon found it necessary to prevent the production of the armature field, or at least reduce it to a minimum, by the employment of compensating windings, such as that patented by Stanley and Kelly in 1892, consisting of short-circuited coils with their axis identical with that of the brush line. Currents were induced in these coils, by transformer action, opposing and more or less cancelling the armature field. In other designs the compensating winding was traversed by the armature current itself, and was connected so as to cancel the effect of the armature ampere-turns. With such motors the magnetic resistance could be reduced to a minimum, and the armature self-induction could still be kept reasonable, though it could never be entirely cancelled, as no compensating winding could deal with the armature leakage flux. The compensating coils themselves also set up a leakage flux, so that there still remained the armature leakage, the compensating coil leakage, and the main flux as causes for the flow of a wattless current.

It is, however, easy to understand that the compensated motor would be preferable to the uncompensated one. The three essential circuits—A, the armature winding, C, the compensating winding, and E, the exciting winding—can be arranged in various ways. The armature or rotor circuit must, of course, always remain an ordinary direct-current winding. The stator can be arranged either with practically continuous iron—*i.e.*, with many slots per pole—or with definite polar projections. The compensating winding should, however, be arranged to be as nearly as possible

* Translation in abstract from the *Elektrotechnische Zeitschrift* for June 2, of a paper read by K. Pichelmayer before the Elektrotechnische Verein, Berlin.

Digitized by Google

identical with the armature winding—*i.e.*, it should be distributed. Excitation and armature, or excitation and compensation, may, under certain circumstances, have a single common winding, so that the motor need only have two independent windings. The three circuits will, however, always be traceable. For the sake of simplicity, the motor with only two windings will be considered. Motors with independent exciting windings are, however, essentially the same. The three windings may be divided between

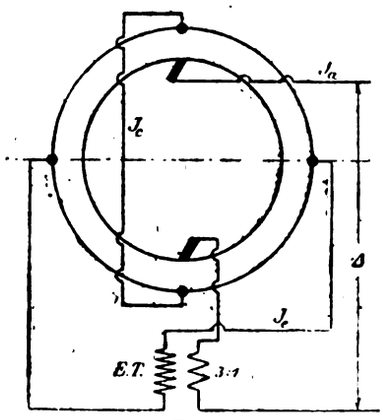

FIG 1.

the rotor and stator in various ways. The following are the possible combinations :

	Stator.	Rotor.	Type of motor.
I.	C E	A	Ordinary compensated series motor.
II.	A	C E	Winter-Eichberg-Latour motor.
III.	A E	C	Thompson's repulsion motor.
IV.	C	A E	Reversed repulsion motor.
V.	A C	E	Impossible combinations.
VI.	E	A C	Impossible combinations.

The combinations under V. and VI. are obviously impossible, since the armature winding and compensating winding cannot both be mounted on either the stator or rotor, as they form the primary and secondary of a transformer. There are, therefore, only four broad types of compensated motors. The arrangements I, II., and III. are of particular interest, and will be compared below. It

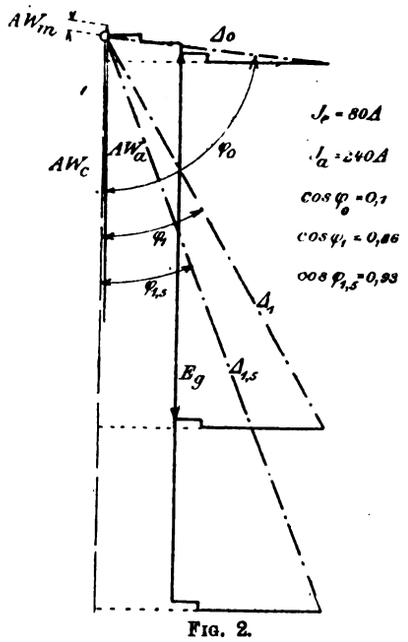

FIG. 2.

will, however, be impossible to give the complete theory of these three motors here, so that for simplicity we will consider a motor of definite dimensions and construction arranged, first, as a compensated series motor, then as a Winter-Eichberg-Latour motor, and, finally, as a repulsion motor. The diagrams for these three arrangements of a motor having an armature diameter of 485mm. and an armature core length of 300mm., are given below with as great accuracy as the present state of the theory will permit. The frequency is taken as 25, and all these motors are supposed to run at 750 revolutions when in synchronism—*i.e.*, they are four-polar motors. The armatures will have ordinary lap windings—*i.e.*, they will have four parallel circuits. The number of total armature-turns will be taken as about 300, giving about 300 commutator segments. The number of stator turns will be taken as equal to those on the rotor, so that stator and rotor both have identical direct-current windings so as to permit of easier com-

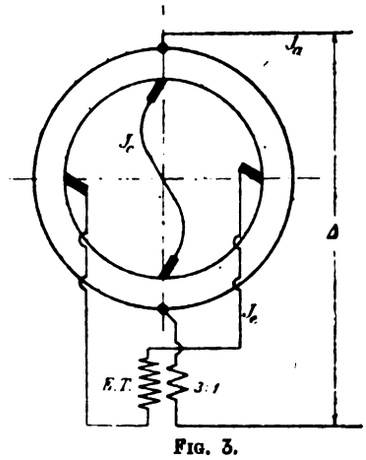

FIG. 3.

parison of the different types. The diagrams are for equal excitation and for an armature current of 60 amperes per circuit, giving a power of about 100 h.p. when running at synchronous speed. The single air-gap between stator and rotor is 2mm.

Consider first the compensated series motor whose connections are shown in Fig. 1. The compensating circuit is coaxial with the armature circuit, whilst the exciting current is introduced at right angles to these by means of a series transformer. This exciting current will be taken as equal to one-third of the main current. The introduction of the transformer is necessitated by the fact that rotor and stator have equal number of turns. In practice, of course, no such transformer would be employed, but the same result would be attained by putting only one-third as many turns on the stator as on the rotor. We are, therefore, dealing with a motor whose field exciting ampere-turns are only one-third of the armature ampere-turns. The armature and compensating circuits form a short-circuited transformer under all conditions of working. The magnetising current—*i.e.*, the resultant number of ampere-turns, A W_m (Fig. 2)—is very small, as the

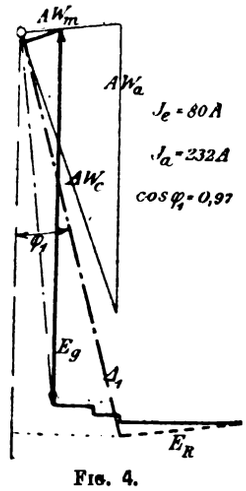

FIG. 4.

resultant field has only to make up for the E.M.F. of the compensation leakage and the ohmic drop in the compensating winding. The action of this transformer remains unchanged under all conditions of motor load. Armature current and compensating current are almost equal, and practically in exact opposition. In the voltage diagram, consequently, all the wattless voltages are almost unidirectional, and at right angles to these two currents. The wattless components of the voltage are obviously the E.M.F.'s of the leakage fields of the armature

Digitized by Google

current, the compensating current, the exciting transformer, and the self-induction of the exciting current itself. The useful component, or counter E.M.F., E_g, is the voltage induced in the rotor by rotation in the main field. The short power components represent the resistance losses. All the power components are shown vertical. The indices 0, 1, 1·5 represent standstill, synchronous speed, and 1·5 times synchronous speed. The diagram shows that at standstill with 240 amperes input the motor requires a voltage $\Delta_0 = 230$ volts, and that at synchronism this voltage must be increased to 460 volts. The value of cos ϕ is satisfactory even at synchronism, and at 1·5 times syn-

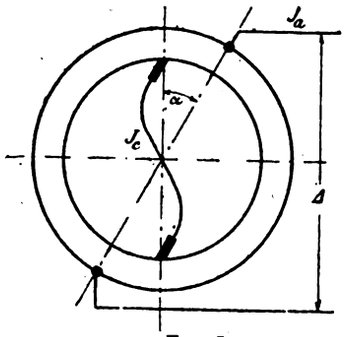

FIG. 5.

chronism the relation of power counter E.M.F. to wattless components is so good that cos ϕ reaches the value of ·93. The motor is, therefore, quite satisfactory as regards power factor. This result is not only theoretically correct, but has been confirmed by tests on a motor of smaller dimensions.

The results are still better if the motor is given the Winter-Eichberg arrangement, as in Fig. 3. It will be seen that with this arrangement compensation and excitation occur on the rotor whilst the armature circuit is on the stator. This apparently small change has a considerable effect on the behaviour of the motor. The chief differences as compared with the series motor is the fact that the field in the compensation axis is very considerable. At standstill the armature circuit and compensating circuit behave like a short-circuited transformer. The torque is produced by the interaction of the armature current and the field (to be called the main field) set up by the exciting circuit, which is, in this case, situated on the rotor. As soon as the motor commences to run, the voltage between the compensating brushes rises and reacts on the stator by transformer action. This reaction can only occur through the cross field, which is practically proportional to the power

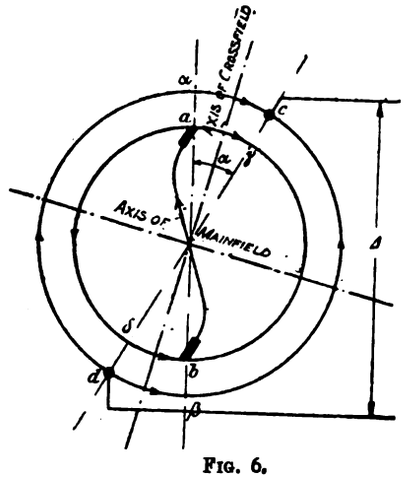

FIG. 6.

component of the voltage, and, therefore, for a given excitation, proportional to the speed. At synchronism the cross field is equal to the main field. If, therefore, the motor is saturated by the main field at synchronism, it cannot very well run above synchronism, even if a greater voltage than that required for synchronism is applied.

In order to use the motor to the best advantage it should, therefore, be built so that its synchronous speed is the highest speed at which it has to run when developing its full torque. Since the cross field ampere-turns are derived from the resultant action of the armature ampere-turns and the compensation ampere-turns, a phase displacement occurs between these two magnetising forces—in other words, between the armature and compensating currents. The diagram (Fig. 4) shows the ampere-turn triangle for the armature current, the compensating current, and the ideal magnetising current for the cross-field. An inspection of this diagram shows that the power component, E_g, of the

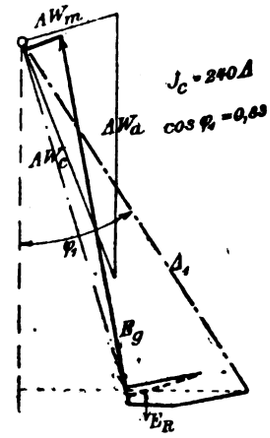

FIG. 7.

voltage is parallel to the primary current or the armature current. It is, in fact, produced by the field set up by the armature current, and any field and the current producing it are necessarily in phase. Of the wattless components, the leakage voltage of the compensating winding is at right angles to the compensating current, and the leakage voltages of the armature and the exciting windings are at right angles to the armature current. The characteristic point of this motor is the production of a wattless counter E.M.F., E_R, by the rotation of the armature in the compensating field. This voltage is in phase with the compensating field, and therefore parallel to the resultant magnetising current or ampere-turns acting along the compensation axis. It will be seen that this wattless component improves the power factor very considerably, so that, at least at synchronism, practically the only wattless components left are those due to the leakage fields, which are naturally very small compared with the power component of the voltage. The field inductance is completely cancelled, and this accounts for the very high power factor. At synchronism, as has been shown by Dr. Eichberg, this motor has a compensating field almost equal to the exciting

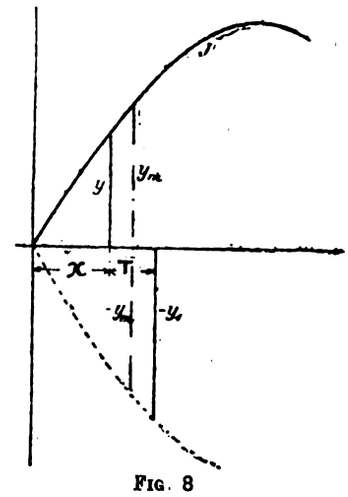

FIG. 8.

field, and approximately at 90deg. phase displacement from the latter. These two fields displaced 90deg. in time, and, in a two-pole motor, also 90deg. in space, produce a rotating field which revolves with the armature, and has an effect on the commutation, as will be shown below.

Considering the same motor next as a repulsion motor (Fig. 5), instead of feeding the armature and exciting circuits independently from four points, they may be fed from only two points situated at an angle to the compensation axis. The amount of this angle depends on the relation

Digitized by Google

of the exciting ampere-turns to the armature ampere-turns. When, for instance, this ratio is 1 : 3, as in the motor in question, this angle would be about 27deg. This angle, as shown in Fig. 6, cuts the portions $a\ \gamma$ and $b\ \delta$ out of the rotor, and in the same way the portions $\alpha\ c$ and $\beta\ d$ out of the stator. In the portions $\alpha\ c$ and $a\ \gamma$ the direction of current is the same, so that this belt of conductors obviously forms the exciting circuit, whilst the conductors lying within $180 - a$ form the transformer or compensating circuit. The field is, therefore, half excited from the stator and half from the rotor. The diagram for this motor is shown in Fig. 7, where the power component of the voltage is made parallel to the average direction of excitation, and is, therefore, somewhat displaced relatively to the primary and secondary currents. The wattless counter E.M.F., E_R, now only compensates for about half the field inductance, whilst that part of the excitation which is due to the stator remains uncompensated, so that the motor should have a somewhat worse power factor than the Winter-Eichberg-Latour machine. In addition, a slight phase displacement exists between the effective field and current, so that the output of the motor is slightly less than that of either of the other two motors. The diagram of this motor (Fig. 7) does not profess to have the same exactitude as those of the other two motors, as the theory of the repulsion motor is by no means complete at present. This motor also sets up a rotating field at synchronism, though it is not so regular as in the Winter-Eichberg motor, as the distribution of the exciting field ampere-turns is very different from that of the compensating field ampere-turns.

The reversed Thompson repulsion motor need not be considered in detail, but it will be seen that with this combination (No. IV., C—A E) the compensating short-circuit is situated on the stator, so that this motor behaves similarly to the compensated series motor.

The four principal types of motor mentioned in the table may be divided into two groups, the first consisting of the C E—A and C—A E combinations, which have the compensation on the stator, and consequently cannot set up a rotating field, since the stationary short-circuit prevents the production of a cross field. In the motors of this group, the short-circuit compensation might be replaced by a compensating winding fed from the supply without materially affecting the action of the machine. The motors of the second group, consisting of the combinations A—C E and A E—C, on the other hand, are real rotary field machines, as distinguished from the first group, which work with an oscillating field. The fact that combinations II. and III. can be worked direct from a high-tension supply, while this is impossible in the case of I. and IV., is of practical importance.

The results of the above rapid comparison may be shortly stated as follows: (1) For the same excitation and the same armature strength all three types of motor give approximately the same torque, since there is practically no phase displacement between the working field and current, and the power components of the current are the same in all three cases. The cross field produces practically no torque, at least at synchronism. (2) The power factor is best at synchronism in the A—C E (Winter-Eichberg-Latour) motor. At starting it is equally bad in all three motors, and approximates to the value ·1, neglecting the losses. (3) The series motor improves its power factor considerably as the speed increases, so that it is suitable for running at speeds well over synchronism—*i.e.*, it may be built with very many poles. (4) With the Winter-Eichberg motor and the repulson motor it is not possible to run above synchronous speed with the higher excitations, as the cross field, which is practically proportional to the power component of the voltage, cannot be increased beyond the saturation value. This means that only the smaller numbers of poles (corresponding to approximately synchronous speed) can be employed with these motors.

From the diagrams it will be seen that all three motors require the same voltage at starting, and this voltage is about 50 per cent. of the voltage required for running at synchronism with the same torque, so that the speeds of all the motors can be very conveniently varied by altering the applied voltage. In this way, for instance, the accelerating torque on a train could be kept constant from start to full speed by gradually increasing the primary voltage, and then reducing this voltage again for steady running at full speed. In the Winter-Eichberg motor an adjustment is also provided in the transformation ratio of the transformer, which determines the ratio between armature ampere-turns and exciting ampere-turns, and by this means a large speed variation can also be attained, though it would not seem to do away with the necessity for primary voltage regulation as well.

The question of commutation in these motors has still to be considered. It is well known that this is the point in which alternate-current commutator motors give most trouble, and though it is constantly stated that these troubles have been overcome, it is certain that only a partial solution of the difficulty has been attained as yet. In the case of an alternating motor, a so-called reactance voltage is set up in the short-circuited coil just as in the direct-current machine. In Fig. 8 the curve of the alternating current is shown. Suppose commutation commences at time x, when the alternating current has the value y. At the end of the commutation period the value of the current is $-y_1$. The time interval between y and $-y_1$—*i.e.*, the time of short-circuit, T—is usually quite small as compared with the alternate-current period, and is smaller the higher the speed of rotation.

In order to calculate the reactance voltage, it is sufficiently accurate to use the average value of y and $-y$—*i.e.*, y_m. The average E.M.F. of self-induction in the short-circuited coil is, therefore, proportional to the instantaneous value of the current to be commutated, and is, therefore, in phase with this current. The maximum value of this commutation voltage will be 1·4 times as great as with continuous current, and this is one cause of the greater tendency to spark observable in alternate-current motors. A further cause of sparking is the induced voltage set up in the short-circuited coil by the transformer action of the alternating flux. This voltage depends on the number of turns per section of the armature, on the number of magnetic lines looped with the section, and on the frequency of the alternating supply. Its value is

$$E_t = 4\ 44\ \omega\ B\ Q\ n\ 10^{-8},$$

where ω is the frequency, B the average induction in the section of the winding, Q the area of the space enclosed by the winding. In order to keep this voltage down, the turns per section, n, must be reduced to the minimum, a single turn being generally found too much even. Keeping B down simply leads to a motor of large size, so that the only available method is the reduction of the frequency. In the series motor dealt with above the value of this transformer voltage comes out at about 7·8 volts, which is too high to permit the motor to work at all. It would, therefore, be necessary to build the machine with eight instead of four poles, and so reduce the transformer voltage to about four, though even this would hardly give satisfactory working.

With those motors which work with a rotating field, this transformer voltage is to a great extent counteracted, at least at synchronous speed. If the rotating field were sinusoidal in form and perfectly uniform in speed, this counter-action would be complete, for at synchronism no cutting of lines could then occur. The field is, however, not quite uniform, so that this cancelling out is never quite perfect. The transformer voltage, which in the motors with oscillating field lags practically 90deg. behind the primary current, combines with the reactance voltage, which is in phase with the rotor current, to form a resultant voltage which it is extremely difficult to reduce below five or six volts, whilst machines with a reactance voltage of only about two volts are already found difficult to operate. The reactance voltage alone of all three types of motor will usually be higher than for a direct-current motor, especially if both stator and rotor have continuous iron faces, so that the short-circuited coils cannot work in an interpolar air-gap. The transformer voltage is least in motors in which the short-circuited coils enclose the smallest area—*i.e.*, in motors of small output or motors with many poles. In the rotating field type of motor the number of poles is

Digitized by Google

more or less fixed by the periodicity, and the transformer voltage is, therefore, large at starting, though as the speed increases this voltage is gradually counteracted. The difficulty of keeping the transformer voltage down increases with the size of motor. Lamme employs high-resistance commutator connections to reduce the short-circuit currents, and numerous other arrangements have been suggested, but without much success up to the present—at least for the larger sizes of motor.

The question of relative output of these alternating motors as compared with direct-current motors must next be considered. The effective (torque-producing) field in all three types of motors is that set up by the exciting circuit. This field varies from a maximum to zero, and produces a periodic torque with the effective current with which it is practically in phase. Calling the maximum obtainable value of the flux in either alternating or direct current machine 1, and the effective value of the armature current in either case $\frac{1}{\sqrt{2}} = \cdot 707$, the torque in the case of the direct-current motor is $1 \times \frac{1}{\sqrt{2}} = \cdot 707$. In the alternating motor the torque follows a $(\text{sine})^2$ curve with a maximum value of 1 and an average value of $\frac{1}{2}$, so that the average torque of the same motor used on alternating current is only ·5, and the ratio of maximum torque attainable as a direct-current motor to that attainable as an alternating motor is about 7 : 5. This difference cannot be avoided, and naturally it forms a drag on the alternating motor in its competition with the direct-current motor. Another difficulty encountered with alternating motors of all these types is the fact that they can only be built for comparatively low voltages. This is due to the fact that, at least in the larger sizes, only one turn per section is permissible, instead of two or three, as with direct currents. Low-voltage armatures involve large commutators. The ordinary compensated or uncompensated series motor is perhaps worst off in this respect, owing to the large number of poles which can and must be used on them. The permissible armature voltage with lap armatures varies inversely as the number of poles. Some improvement can, however, be obtained by employing series or series-parallel armature windings. It would appear as if the motors of the rotating-field class would be better in this respect than the motors with oscillating field, as with the latter the whole energy of the motor is conveyed through the commutator. This is, however, by no means the case, for, though it is true that the energy conveyed through the commutator of the rotating-field motors at synchronism is only a small percentage of the whole energy supplied to the motor, the size of commutator required is much the same as for the oscillating-field machines.

It is entirely incorrect to suppose that the energy transmitted by a commutator is a measure of its size. All three types of motor must have as many armature conductors as possible, so as to obtain the maximum possible armature voltage. All three types—at least, above a certain size—can only have one turn per section. The minimum size of commutator segment is a fixed quantity, and alike for all the motors. Further, the necessary commutator surface is in all cases decided by the commutator losses, and these, allowing for railway work with frequent starting, are about alike in all three motors, so that all require about the same commutator size. The Winter-Eichberg motor has, it is true, very small short-circuit losses on the commutator and in the armature at synchronism, but then it has the extra sets of brushes for the exciting current.

With regard to efficiency at full load, the ordinary series motor is perhaps worst off, as it runs above synchronism, and so has more iron losses and also more short-circuit losses, which may reduce its efficiency several per cent. below that of the other types. Of the practical value of all these types of motors in heavy railway work nothing is known at present. It is possible that, in their gradual development, the undoubted advantages of the single-phase motor may be found to outweigh all their disadvantages, and even that some method of overcoming the commutating troubles either by a fresh electrical arrangement or by the employment of different materials for commutator and brushes may be discovered. On the other hand, it is possible that a return may be made to direct-current motors, which are still capable of considerable improvement. In any case, the attempt to introduce the single-phase system will have a good effect on the electrical railway industry, and may lead to the perfecting of a system suitable for universal application for light and heavy traction, for single motor carriages, for long trains and for locomotives, and for short and long distance work.

NORWICH ELECTRICITY ACCOUNTS.

From the accounts of the Norwich Corporation electricity department up to Dec. 31, 1903 (one year and three months' working), it appears that the total expenditure on capital account to that date amounted to £261,547. Abstracts of the revenue account, etc., are appended.

Dr.	Revenue Account.	£	s.	d.
Generation of electricity		10,734	13	0

APPOINTMENTS VACANT.

Tramways Manager and Engineer, Huddersfield Corporation. Salary, £350 per annum. Applications by noon on Aug. 8. See advertisement.

Electrical Engineer, Heston and Isleworth Urban District Council. Salary, £250 per annum. Applications to Mr. H. J. Baker, clerk, Town Hall, Hounslow, by Aug. 6.

Chief Assistant Electrical Engineer, Weymouth. Salary, £120 Applications by Aug. 10.

Cable Companies and Wireless Telegraphy.—Sir J. Wolfe Barry, when presiding over the meeting of the Eastern Telegraph Company last week, said that the directors intended to make use of wireless telegraphy. While holding the view that wireless telegraphy would not compete with long-distance submarine telegraphy, they thought there were places where wireless telegraphy could be usefully employed. A case in point was the Azores, where the cables of the associated companies touched. It was desired by Portugal that some of the outlying islands should be placed in telegraphic communication. Owing to the nature of the bottom and the landing place of these islands, it was not considered a suitable place to make the connection by cable, neither would the traffic warrant an expenditure on this account. They therefore intended to connect the points by a system of wireless telegraphy, to be worked in connection with their cable system.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Bound Volumes of "THE ELECTRICAL ENGINEER," *containing half-year's copies, bound in Dark-Blue Cloth, Gold Lettered, price 8s. 6d. New Volume, January to June, 1904, now ready.*

GOVERNMENT BY MAJORITY.

The clauses of the 1904 Supply of Electricity Bill have the commendation of electrical engineers as a whole, and the few exceptions, which are electric lighting company engineers, seem likely to be converted before the measure becomes law. We are not surprised, however, to find that the Bill is not so favourably received by the gas interests. Thus, our contemporary, the *Journal of Gaslighting and Water Supply, etc.*, has this week as a heading to an article about this Bill, "A Serious Menace to Gas Companies' Interests." Our contemporary invariably takes extreme views of the competition between gas and electricity for lighting purposes, and on this topic we do not now propose to touch. Neither do we propose again to enquire into the *bonâ fides* of the defunct Bermondsey clause, which was nominally introduced to protect the ratepayers of a community against the acts of their elected representatives. What we do propose to criticise is a statement in the article headed as above, which reads as follows: "But what voice have the ratepayers under the provisional order system? Absolutely none." Our contemporary then details the protection which it considers ratepayers have when powers similar to those now proposed to be granted by provisional order are sought by way of a Bill. These are well known to our readers. Our contemporary contrasts with them the procedure in connection with a provisional order. It says that "in this case no borough fund proceedings are applicable, the ratepayers and the Local Government Board are not consulted, and the Board of Trade ask no questions—in short, the orders are handed over almost as a matter of course where there is no opposition. The only opportunity a ratepayer has of expressing his views at all is when the Local Government Board hold an enquiry respecting their sanction for a loan. But then—mark the distinction!—the enquiry is not for the purpose of determining whether the money should be raised, or of determining whether the powers of the order should be carried into force, but solely for the object of settling how much money is to be spent. If a ratepayer goes into the room, and protests that the works in question are not wanted, he will be told that this is not the concern of the Local Government Board, and that (the provisional order having been granted) the only duty of the Board is to say how much money they should authorise for the objects in view." We quite agree with the truth of what our contemporary states as far as the interference from a small body of ratepayers is concerned. We deny emphatically, however, the truth of the preliminary statement that ratepayers have absolutely no voice in what shall be done under the provisional order system. In the first place, the ratepayers elect the members of a corporation, and as a rule the projects to be brought before the corporation in any one year are vigorously discussed at the November elections. Having thus elected their representatives, it is absurd to say that they have no voice in the control of the undertakings of the corporation. If the party in power obtain a provisional order and decide to spend a certain amount of money on the same, this question has also to be voted on by the elected members of the corporation before application is made to the Local Government Board. To show the point of the view which Cabinet Ministers take of this matter, we remember the reply which Mr. Austen Chamberlain, when Postmaster-General, gave to a deputation from the Tunbridge Wells Ratepayers' Association with respect to the telephone question. At the time the Corporation of Tunbridge Wells had, through the instrumentality of the town clerk, agreed to sell its municipal telephone undertaking to the National Telephone Company,

Digitized by Google

there was strong opposition from a large body of the ratepayers, but the Corporation had voted in favour of the scheme. These ratepayers then asked the Postmaster-General to refuse to give his consent to the agreement on the ground that it did not meet the views of the majority of the ratepayers. The reply was to the effect that Mr. Austen Chamberlain could not entertain the view that the elected members of the Corporation of Tunbridge Wells did not represent the wishes of that town. Our contemporary would be equally correct if it said that Sir George Livesey, as managing director of the South Metropolitan Gas Company, did not represent the shareholders in that company, and hence it was a great injustice that he should make them responsible for a possible loss on expenditure in which they have had no voice. We are quite sure that neither Sir George Livesey nor the members of any electric light committee will continue to control their respective undertakings unless they do so in such a way as to command the confidence of the shareholders or ratepayers respectively. The reasoning in the new Electric Lighting Act which upsets our contemporary is that under it local authorities will be more able to conduct electric lighting undertakings on business lines, which was quite impossible with the Bermondsey clause in force.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

BELT CALCULATIONS.

SIR,—In the *Electrical Engineer* for July 15 there appears an interesting article on "Belt Calculations," which, undoubtedly, is from the pen of an engineer, and has also come at a most appropriate time. But I do not quite understand why he should dispute the advantages gained in a long drive even if both pulleys are of the same diameters. Personally, I have always thought and most engineers will tell you that it is an advantage. However, he admits that it is in the case of the pulleys being of different diameters, but he neglects to say what would be a reasonable length, one that would give the best results without an unnecessary waste of leather, say, in the case of the ratio of the two diameters being, say, 3 to 1 and 5 to 1. If Mr. Yrreb could help me in determining these I should feel great obliged.—Yours, etc.,

M. WOLVERHAMPTON.

SIR,—Respecting the article on "Belt Calculations" which appeared in your issue of the 15th ult., the article, on the whole, is certainly a very good one, and one that will be found useful to general engineers and millowners. But I notice that Mr. Yerreb entirely omits a constant, or factor, for determining the proper thickness of leather he would use, which is a most important item when running at high speeds and large ratios. Surely he would not use the same thickness in every case.—Yours, etc., N. L. G.

LIGHTING, HEATING, AND VENTILATING AT THE NEW HALL OF THE ROYAL HORTICULTURAL SOCIETY.

This new hall was opened by the King on July 22, and its construction was most favourably commented on at the opening ceremony. Owing to the peculiar nature of the building, the question of lighting, and more particularly of heating, required special consideration, as the effects of cold draughts from the roofs would be disastrous to orchids and other valuable plants which will so frequently be exhibited in the hall. When a room is warmed from below the heated air naturally rises, and if the roof is of glass at a much lower temperature than the room, the air is rapidly cooled down and falls again, giving a cold draught, producing exactly the same effect as if cold air were actually finding its way in through openings in the roof. To avoid this in the new hall of the Royal Horticultural Society, the consulting engineers have adopted the novel plan of running on each side of each of the main girders of the roof two 2in. iron pipes, to which steam at a pressure of 15lb. per square inch is admitted. These pipes have a total radiating surface of over 1,000 square feet, and serve to keep the roof at such a temperature that the warm air from above is not cooled down, but passes away through the ventilating fan in the roof.

In the basement below the hall are four chambers, each containing steam radiators. Air is drawn in through four inlets, carried to the top of the building, passed through canvas screens and through a water spray to cleanse it and add the necessary moisture, and then by means of four powerful electric fans forced over the heater coils and delivered through four openings, two at each end of the hall, about 10ft. above the floor line. The speed of the fans, and therefore the amount of heat delivered to the hall, can be varied as desired, and in summer-time the fans will deliver cold washed air. In addition, there is a 36in. exhausting fan in the roof which can be worked as required.

The library, board-room, staircases, offices, and other portions of the building are heated by means of low-pressure steam radiators, of such a size that with an outside temperature of 32deg. F. the rooms can be easily kept at a temperature of not less than 60deg. F. Steam is supplied by means of a 9ft. by 5ft. 6in. "Economic" boiler fixed in boiler-house in basement, the steam, when condensed, being returned through traps to the hot-well, from which it is again pumped into the boiler by means of a Worthington pump. In addition, there is in the boiler-house a small auxiliary boiler to supply hot water to the lavatories, and for cleaning purposes in the summer, when the main boiler will not be worked.

The building is lit by means of 26 arc lamps and 200 incandescent lamps. The wiring has been arranged throughout to comply with the requirements of the London County Council for public buildings, the lights being divided approximately equally on two distinct services from the mains of the Westminster Electric Supply Corporation. It is also again sub-divided, so that the current consumed in the hall, annexes, lecture-room, cloakrooms, and other rooms, which may be let for entertainments, can be metered separately from the library, offices, and other rooms peculiar to the society. The installation has been carried out on a system devised by the consulting engineers, Messrs. Handcock and Dykes, the wires being drawn into drawn brass tubes, with cast-brass joint and switch boxes. The brass tubes are concealed throughout in the plaster of walls and cement floating of floors, the small size of the brass tubes enabling them to be covered by the plaster without having to chase the walls. All joints between tubes and between tubes and boxes are soldered so as to make an air and watertight junction, thus preventing condensation in the pipes, which frequently leads to failure of the wires. The sub-circuits are grouped to distribution fuse boards on the various floors, the circuits to these various boards being all controlled from the office in the entrance hall.

The main hall is lit by means of 20 arc lamps suspended about 20ft. above the floor-level, so arranged that they can be quickly lowered to the floor for cleaning purposes. In addition, there are a number of three-light brackets round the walls for incandescent lighting, the fittings for these, together with the various electroliers and pendants, being made by the Art Fitting Company, Limited, in "Pewtal," a white non-tarnishable metal. Sockets are also provided in the floor of the hall to allow of temporary lighting when required for decorating stalls or benches down the hall. The lecture-room is provided with sockets at each end from which current can be obtained for working an electric lantern for showing slides, etc., arrangements being made that the lecturer can turn off or on the rest of the lights in the lecture-room at will from either end.

The contractors for the heating and ventilating were Messrs. Kinnell and Co., 65, Southwark-street, S.E., and for the lighting the National Electric Wiring Company, 34, Victoria-street.

LETTERS FROM AN OLD HAND TO A YOUNG ONE.

I.—On the Choice of Engineering.

My Dear Young 'Un,—Your letter of yesterday's date to hand, announcing that you "have decided to become an Electrical Engineer." Why use capitals? There is nowadays no more common noun than "engineer"; anyone from a bellhanger to a wireless telegraphist is electrical. Thanks for giving me early notice of competition. It is the age of young men, and we, products of effete training systems, have only our experience to rely on. Or is your letter a gentle hint that you want me to find you a job?

I am going to take the privilege of a friend—to make myself disliked—by offering that which the clergy call "a word in season." Have you *decided on*, or only *fancied*, engineering? Most fellows between the ages of 15 and 19 are attacked by "calf-love." They pick up some girl to whom they write verses, waft kisses, and swear evermore to be faithful. And between the ages of 24 and 42 they usually marry—some other girl! Are you sure that engineering is not your calf-love among the professions? Let me assure you that picking a wife and choosing a profession are the two most appalling jobs a man has to go through. Generally speaking, the biggest fool chooses in the biggest hurry. Of the two choices, that of a profession is perhaps the more serious. When you marry, there is always the off-chance of a separation; but if you give your profession the go-bye, you must start life again. Unless you care enough for Engineering to say that for the love of Her you will be satisfied if She gives you, in return for hard days of work and long evenings of study, just enough to live on decently, you had better go Bank-clerking or butter-slapping.

Look at it this way: In an average engineering firm the number of men who get enough to pay income tax will not exceed 5 per cent. of the whole crowd; if it did, the firm would be all head and no tail. The bulk of the 95 per cent. are probably keeping wives and families, and wishing they had never been born. Or look at it another way: The technical colleges are every year turning out crowds of energetic youngsters, chock-full of theory, willing to work for experience and 5s a week in an already overcrowded labour market. In addition to these are the shoals of youths who start as apprentices, pupils, improvers, or anything else in the cub stage you like to call them. Or, take a look at the "Gazette"—it is healthy reading occasionally—and tot up the number of small engineers who go to pot every year. Of course, I know you are a smart boy, and have honest intentions of becoming President of the Institution of Civil Engineers. But suppose you don't?

A friend of mine once had a craze for railway engineering. He had family influence with the Chief Engineer of one of the lines, and so he felt sure of a soft berth. One of the first questions fired at him by the great man was, "Have you ever built yourself a wheelbarrow?" To which he had to answer "No!" "Or a model yacht?" "No!" Whereupon the Chief intimated that the applicant would be of no condemned service to any Railway Company, and requested the honour of his absence. Only the manner of speaking was more abrupt. My friend took the hint, became an estate agent, and can now buy himself a fancy waistcoat without docking his laundry bill.

That is the test! If you *can't help* using your hands—if you as a kid tied all the chairs together with string and sewing-cotton spools to make the wheels go round, and cut yourself with the carving knife making a boat—then you are an engineer. If you didn't, you aren't. If you aren't, don't try to be; there are plenty who are. You have only one life to live, and you might as well live it according to your instincts.

Another point: If you have any recollection of past mercies, you will remember that last winter I took you to the theatre. There was a fearful crowd round the door when we got there, but we edged round, and by paying a little extra we went in at the early door and got a front seat. I lay this before you as a parable. Assuming that you *are* an engineer, why should you be electrical? I trust you don't bet—bad habit for tender years—but if you meet an engineer, you can lay 6 to 1 that he is electrical. Why?

It has apparently slipped the notice of many young fellows that they can become hydraulic engineers, shipbuilders, bridge and roof constructors, motorcar makers, quite as easily as electricians. If you are wise, and have no overpowering aptitude (I don't say inclination) for electrical affairs, you will keep out of the crush and get your position by the early doors. The only extra expense is a little more thought in making the first choice. Believe me, present-day electrical engineering is by no means Tom Tiddler's ground, whatever it may have been.

If, after all, you decide to be an electrical engineer, put your back into it. Don't hesitate to soil your lily-white hands, and don't be happy till they've grown corns where the blisters were. And—if you will take a word in confidence—you had better throw up that girl who is making a fool of you and buy "Dynamo-Electric Machinery." You haven't time for both.

You might as well write and let me know what you are going to do, for there is no need for you to break your shins on exactly the same rocks that I met.—Yours,

The Old 'Un.

THE WORKING OUT OF INDICATOR DIAGRAMS.

BY H. E. HODGSON.

(*Concluded from page 131.*)

5. *Ordinate Method.*—This method consists of dividing the diagram into a number of equal vertical strips, and arithmetically finding the mean height of these strips. This height, measured by means of a scale corresponding to the spring used, will give the mean effective pressure.

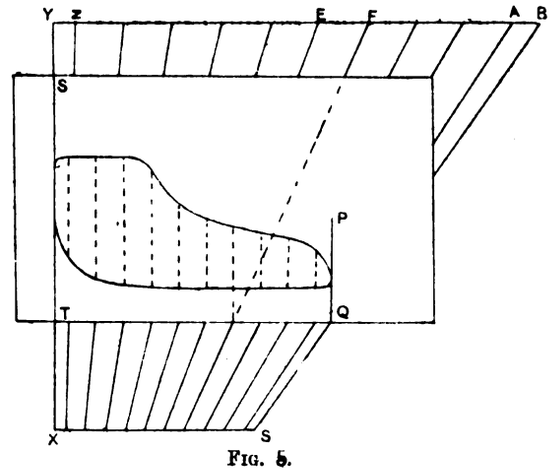

Fig. 5.

It is usual to use 10 strips for diagrams up to 3in. in length, and 12 to 15 strips for diagrams longer than this. There are numerous methods of dividing the diagram into the required number of strips, some of which are as follows:

1. *Dividers.*—This method consists of obtaining by trial the correct length, stepping off 10 equal distances along the atmospheric line, and setting up lines at right angles to this line at points midway between those already found. The sum of the portions of these lines intercepted by the curve, divided by 10 will give the mean height.

2 *Radial Diagram.*—Another and much quicker method is by the use of a radial diagram similar to that shown in Fig. 5. The line X Y is made vertical, and all the other lines radiate from some point in X Y produced. In order that the middle heights only may be drawn without the corresponding boundary lines, the distance between the last and the last but one lines from each end are only half a strip apart, so that 2 Y Z = 2 A B = E F. To use the radial diagram, take the indicator card and draw lines S T and P Q perpendicular to the atmospheric line touching each end of the diagram. Now move the indicator card up or down with the line S T coinciding with the line X Y in the radial diagram until the point Q in the line P Q comes on to the right-hand inclined line, B C. Then mark the bottom of the card where the radial lines cut the edge, draw verticals through these points, and find the mean as before.

3. *Parallel Rule.*—The parallel rule shown in Fig. 6 enables the divisions into 10 parts to be readily accom-

Digitized by Google

plished. The rule is extended over the diagram until the front edges of the first and last strips or bars touch the two ends of the diagrams, as shown in Fig. 6. The bars must be perpendicular to the length of the diagram, but usually this can be done with sufficient accuracy by the eye alone. While the rule is thus set draw a pencil along the front edge of each of the bars and measure the mid-heights as before.

4. *Ordinary Scale.*—A fourth method of doing the same thing is shown in Fig. 7. Draw vertical lines, A B and C D, touching the ends of the diagram. Take an ordinary scale and place it diagonally across the diagram with the zero on A B and the tenth division on C D. Mark with a

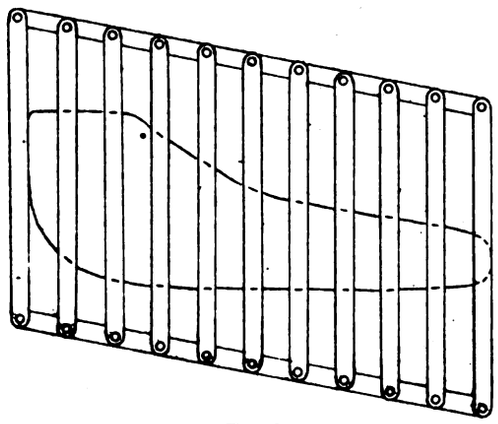

FIG. 6

pencil the middle point of each of these scale divisions, and through these points draw lines parallel to A B or C D. These lines are mid-ordinates, and their mean can be found as before.

5 *Slide Rule with Pointed Cursor.*—Slide rules provided with a pointed cursor have usually an improved scale on the bevelled edge—viz, inches and fiftieths of an inch. To divide up a diagram, the slide rule is used in the same way as an ordinary scale. In the ordinary way 10 separate heights have to be measured, but with the pointed cursor the successive ordinates are added continuously. The method employed is shown in Fig. 8. Place the zero of the scale at the top of the first ordinate and the pointer at

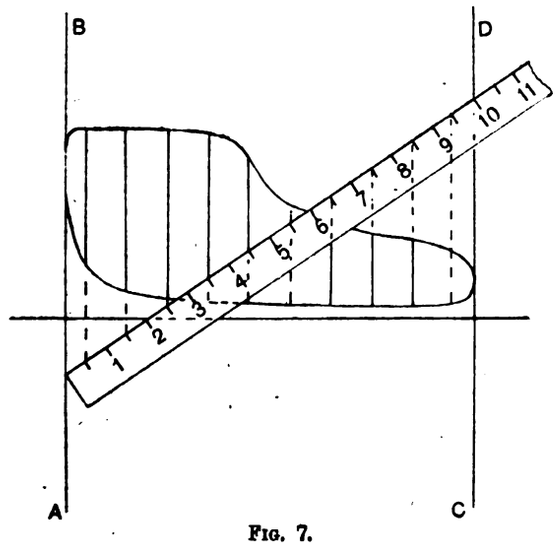

FIG. 7.

the lower end; then shift the rule so that the pointer is at the top of the second ordinate and the rule along its length; run the pointer along until it is opposite the lower end of the second ordinate, and so on. Only the final reading need be noted. This figure, multiplied by the number of the spring divided by 10, will give the mean effective pressure. It will be seen that by this method there are fewer processes, and, therefore, less possibility of error. A further advantage is that the complete process can be performed without writing down a single figure, resulting in a great saving of time. Sometimes during an engine trial the mean effective pressure is required as quickly as possible. In such a case the following method gives a good approximation: Draw the end and middle ordinates, as in Fig. 9; then draw the straight line A B so that as near as possible the sum of the areas X, Y, and Z equals the sum of the areas S and T. Next draw the line C D so that the sum of the areas E and F equals the area G. The intercept of P Q, the mid-ordinate between these two lines, equals the mean height required.

DETERMINATION OF THE STEAM CONSUMPTION FROM THE INDICATOR DIAGRAM

The determination of the weight of steam entering the cylinder per stroke cannot be estimated from the indicator

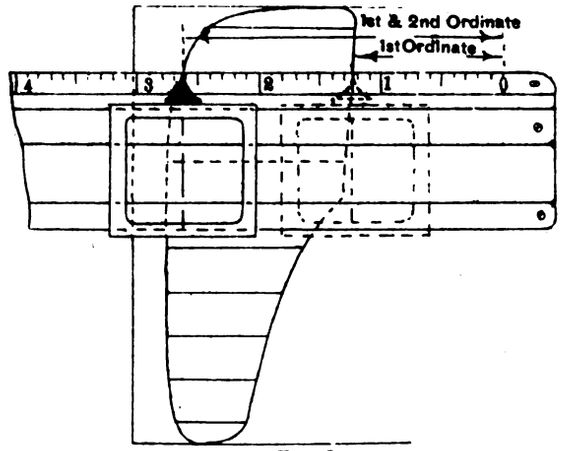

FIG. 8.

card as accurately as the indicated horse-power. If we measure the pressure and volume of the steam in the cylinder at any point between the points of cut-off and release, we can by reference to the steam tables find the weight of steam present. To do this on the indicator card, we must find the lines of zero pressure and zero volume. The zero pressure line can easily be found by setting off a distance equal to the atmospheric pressure to the scale of the spring below the atmospheric line, and drawing a line parallel to it through that point. To find the zero volume line, we must know the clearance volume of the engine; if this is known, proceed thus. Set out a distance E F (Fig. 10) such that E F is the same fraction of F G that the clearance space is of the working volume. At the point E erect a perpendicular to the zero pressure line; this line is the zero volume line.

ESTIMATION OF THE CLEARANCE VOLUME FROM THE INDICATOR DIAGRAM.

The clearance volume is best found by filling the cylinder with water or by calculation from the working drawings.

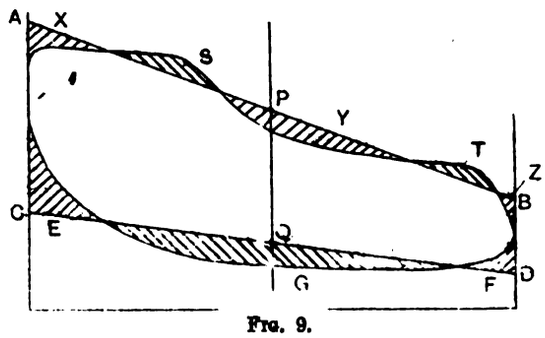

FIG. 9.

But it may be found approximately from the indicator card if there is no leakage; to do this, the expansion curve is assumed to be a rectangular hyperbola. It is found that the expansion curves on cards taken from well-designed engines of not too small a size and in good running order do not differ much from this curve.

Method.—Take any two points, A B (Fig. 10), on either the expansion or compression curve, and draw horizontals and verticals through each of these points intersecting at C and D. Join C D and produce it to cut the zero pressure line in E A vertical through E will give the zero volume line, and $\frac{E F}{F G} \times \frac{100}{1}$ equals the percentage

Digitized by Google

clearance. This should be done for a number of points both on the compression and expansion curves. The produced lines should all intersect in the one point E; actually they will not, so a mean should be taken. Having obtained our zero lines, we may now proceed to measure off corresponding values of pressure and volume for different points on the expansion curve. Look up the volume of 1lb. of steam at each pressure and find the actual weights of steam present. For instance, if the pressure at X = 45lb. per square inch, and the volume = 1·8 cubic feet, the steam tables tell us that 1lb. of steam at 45lb. per square inch pressure occupies 9·2 cubic feet. Hence at the point X we have $\frac{1}{9{\cdot}2} \times \frac{1{\cdot}8}{1} = {\cdot}196$lb. of *steam* present. But it will be seen that at the point K there is a certain amount of cushion steam already trapped in the cylinder, hence the weight entering will be the volume indicated less this amount. It will also be found that the weight of steam indicated as in the cylinder will be least just after cut-off and greatest just before release. But the amount of water stuff in the cylinder after cut-off is constant, and is usually some 1 or 2 per cent. greater than the weight of *steam* indicated at release. At cut-off the weight of steam may be only 75 to 80 per cent. of the total water stuff; the remainder is water formed by initial condensation. This

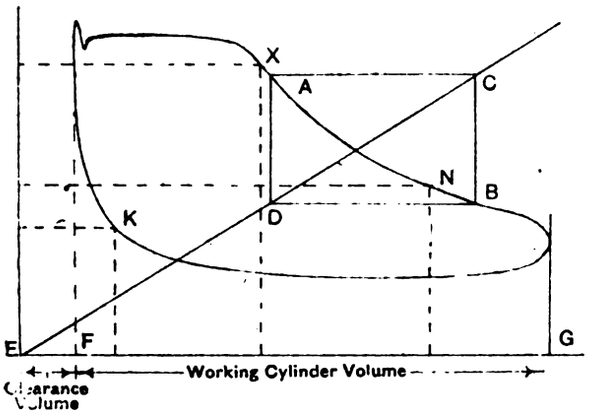

FIG. 10.

water is partially re-evaporated by heat taken from the cylinder walls during expansion.

COMBINATION OF DIAGRAMS FROM COMPOUND ENGINES.

It is often useful to reconstruct a set of indicator diagrams, so that they appear in the new figure as if the steam had acted all the time in the low-pressure cylinder only. The diagrams as received from the indicator have for convenience in working different scales of pressure, and also the lengths of the diagrams are made to suit convenience in taking. Now, as the base line of the indicator diagram is volumetric, when representing these diagrams to the same scale the bases must be altered to suit the volumes of the respective cylinders, and one pressure scale must be employed throughout. The strokes are in most cases equal, and hence the respective volumes are proportional to the square of the diameters. In the compound diagram at A set up a scale of absolute pressures, and horizontally any convenient scale of volumes. Set up vertical lines at A_1 A_2, B_1 B_2 (Fig. 11), such that O A_1 is proportional to the high-pressure clearance volume, and O A_2 to the low-pressure clearance volume; also A_1 B_1 to high-pressure cylinder volume, and A_2 B_2 to low-pressure cylinder volume. Divide the lines A_1 B_1 and A_2 B_2 into 10 equal parts and set up verticals. Divide the diagrams in a similar manner, measure the ordinates of each diagram to an absolute scale, and set them up at corresponding points in the combined diagram. The curves thus obtained show at a glance the comparative amount of work which is being performed in each cylinder, and, further, how nearly the total area corresponds to that which would theoretically be obtained in a single cylinder.

THE QUALITY OF THE STEAM.

The quality of the steam during its passage through the engine can be very conveniently represented on the indicator diagram by means of a simple construction. It is first necessary to construct the combined diagram in the manner previously described. If the compression curves do not exist throughout the range required, a rectangular hyperbola should be drawn, so as to form a continuation of the compression curve, as shown at C and D in Fig. 11. An easy graphical method

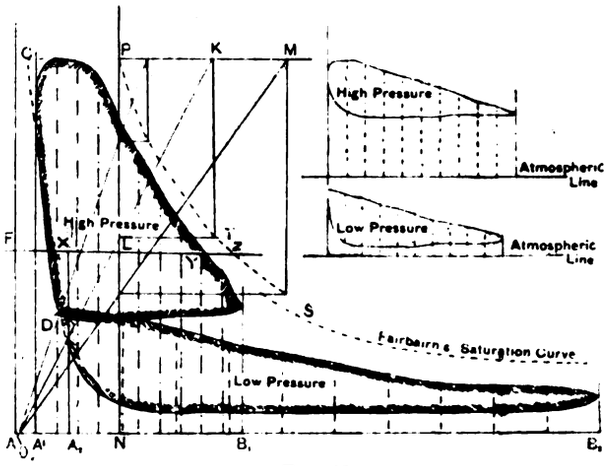

FIG. 11.

of describing a rectangular hyperbola through a given point, P, with a given centre, O, is shown in Fig. 11. Through P draw a horizontal, P M, and a vertical, P N. From O draw radial lines, such as O L K, cutting P N in L and P M in K. Through L draw a horizontal cutting the vertical through K in T, then T is a point on the required curve. Repeat this process to obtain other points. From a knowledge of the steam consumption of the engine the weight of steam used per stroke can be found, and by reference to the steam tables the volumes corresponding to this weight of steam at pressures somewhere near the initial pressures in each cylinder may be found. Then from C set off C P equal to the volume of the given weight of steam at a pressure A C, and from D set off D S equal to the volume of the same weight of steam at a pressure A D. Through each of these points a saturation curve must be drawn, which for rough purposes may be a rectangular hyperbola centre, O. But for greater accuracy the curves

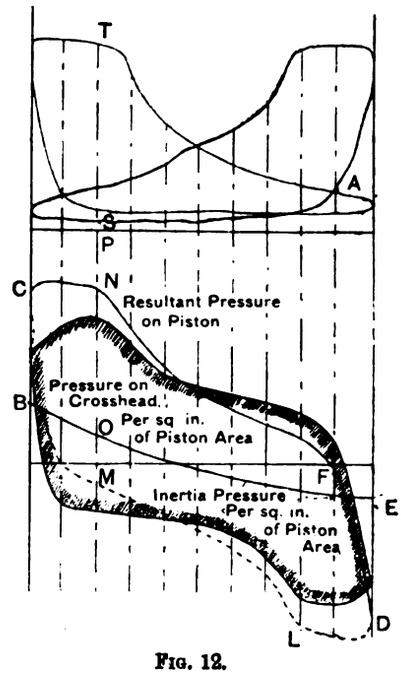

FIG. 12.

should be plotted to Fairbairn's equation—viz., $(p + {\cdot}35)(V - {\cdot}41) = 389$. To do this the origin is merely shifted ·35lb. below the old origin and ·41 cubic feet to the right, and a hyperbola drawn in the usual way. It will be noticed that there is a separate saturation curve for each cylinder of a compound engine. This is due to the fact that the ratio of the clearance volume to the volume swept out by the piston is in general different for the two cylinders. Draw any line, F X Y Z, cutting both the compression and expansion curves, then F × equals the

Digitized by Google

volume of cushion steam, X Y the volume of steam in the cylinder, and if P T Z is a saturation curve, Y Z must represent the volume of water stuff existing as water. Hence, assuming the cushion steam is dry, which is very nearly the case, the dryness fraction F Y/F Z. This quantity may be ascertained for other points in the stroke by measuring similar intercepts.

CURVE OF RESULTANT PRESSURE ON THE PISTON.

The actual indicator diagram does very little more than show the varying change in the pressure and volume of the steam on either side of the piston. The actual pressures tending to move the piston are not shown, at least not without a small alteration, and, further, what is more important, the actual forces on the cross-head are considerably different. The difference arises from the additions and deductions which are required to stop and start the reciprocating parts at the end and beginning of the stroke. At any point P in the stroke the forward pressure is represented by P T (ordinate of one diagram) (Fig. 12), and the back pressure by P S (ordinate of the other diagram). Hence the effective pressure on the piston is the difference between these two and equals P T − P S = T S. At the point A the back pressure is equal to the forward pressure, hence the effective pressure is zero. Therefore, if we plot values of T S as M N (Fig. 12), the outline of this curve will cut the base line at F, and for the remainder of the stroke the resultant pressure will be negative. If the return stroke is treated in the same way, the dotted outline will be obtained; the area included between these two curves represents the net work done on the cross-head during two strokes.

CORRECTION OF THE INDICATOR DIAGRAM FOR INERTIA.

To correct for the inertia of the reciprocating parts, we must first find a curve showing the acceleration of these

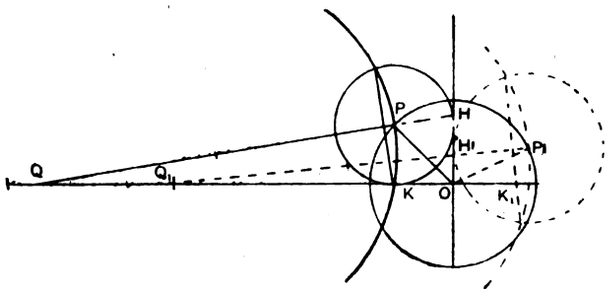

FIG. 13.

parts at different points of the stroke. This is easily performed by the graphical method shown in Fig. 13. PP_1 is the crank pin circle to some scale, preferably the same scale as the base of the indicator diagram; O P is one position of the crank and P Q the corresponding position of the connecting rod. Produce the connecting rod to cut the vertical centre line in H, with P as centre and P H as radius, describe a circle. On P Q as diameter describe a circle and join the points of intersection of these circles, and produce the line to cut the horizontal centre line in K. Then the acceleration, a, at the point, P, $= K O \times a^2$, where a = the angular velocity of the crank $= \frac{2\pi}{60} \times$ revolutions per minute. But the inertia force is proportional to the acceleration, and hence the total inertia pressure $= \frac{W \times a}{g}$, where W = weight of reciprocating parts $= \frac{W \times K O \times a^2}{g}$ lbs., and the pressure per square inch of piston area $= \frac{W \times K O \times a^2}{g \times A} =$ constant $\times$ K O. Find the value of K O for several crank positions, and plot the quantity (constant $\times$ K O) at corresponding points in the resultant pressure diagram, as at M O (Fig. 12). If the engine is a vertical one, the inertia curve must be shifted vertically an amount equal to the weight of the reciprocating parts divided by the area of the piston; then ordinates of the curve B C N D E give the forward pressure, and ordinates of the curve B E D L C the backward pull on the cross-head. These ordinates have been replotted and the shaded curve obtained.

MECHANICAL DRAUGHT FOR BOILERS.*

BY WALTER YATES, M.I.MECH.E, SWINTON.

Perhaps by way of introduction to the subject of producing boiler draught by mechanical means, a few remarks on the combustion of fuel may not be out of place. Carbon is, of course, the principal ingredient in any fuel we desire to use for steam-raising purposes, and it is because carbon is such a large constituent of coal that this material is used almost exclusively for this purpose. Without going in detail into the chemical processes of combustion, it is perhaps sufficient to say that the three elements it is desired to combine are carbon, hydrogen, and oxygen. An evidence that combustion is complete is when it is found that the carbon leaves the hydrogen with which it has been associated, and unites with the oxygen to form carbonic acid. The liberated hydrogen also unites with the oxygen, and forms water; this is usually maintained in its gaseous condition. If upon dissociation a portion of the carbon which is liberated in incandescent particles does not immediately meet with its complement of oxygen, it is liable to become cooled to such an extent by the surrounding gases, that when it reaches an abundance of oxygen its temperature will be too low to permit of chemical union It will therefore pass off as unconsumed and visible carbon in the form of smoke.

For the complete combustion of 1lb. of carbon there are required 2⅔lb. of oxygen. Air consists by weight of 0·236 parts oxygen, therefore the amount of air required for the combustion of 1lb. of carbon must be 11·3lb. It is, however, unnecessary for practical purposes to estimate to a nicety the weight of air necessary for the combustion of fuel, for the variableness in the combustion renders all ordinary calculations approximate only. It is, therefore, the common practice to estimate the amount chemically required for coal at 12lb., or, say, 150 cubic feet per pound of fuel. It is found, however, in practice that the chemical requirement is very much below that actually needed for complete combustion, due to causes which it is unnecessary to enter into here, and it is customary to provide for double this quantity, or 24lb. of air per pound of fuel where natural draught is to be used with hand firing. With mechanical draught, however, this excess of air over the chemical requirement is much reduced, becoming about 18lb. of air per pound of coal. An insufficient supply of air causes imperfect combustion of the fuel, indicated by the production of smoke. An excess of air causes waste of heat. The maximum efficiency is, therefore, to be secured between these two extremes.

Before proceeding to the consideration of mechanical draught, it may also be desirable to refer to a few points in natural draught. Natural draught is that produced by a chimney. The only openings to a chimney should be at either end of it, the top allowing the hot gases to escape, and the bottom, represented by the boiler, allowing the cold atmosphere to flow in. Under these conditions the inflow would continue till the internal walls of the chimney fell to the temperature of the external, when the flow would cease, and commence flowing upwards or downwards as the temperature rose or fell. This explains the bad effect on draught of a leaky chimney. This leakage of air through a chimney or boiler setting has a very serious influence on the draught, and is often accountable for a very greatly decreased efficiency; not only is this the case with faulty brickwork, but it takes place where the mortar joints are apparently sound. The effect is, of course, to increase the volume of air to be handled and decrease the temperature, resulting in a reduction of the draught in the chimney. Chemical analysis of the gases taken from the back of a boiler, and again at the base of the chimney, have frequently shown a great increase of free oxygen in the latter position over that found in the former.

If the temperature of the chimney falls below that of the atmosphere there is a down draught, a good example of which is a fire being lighted in a damp or cold room in a house. Draught, then, is caused by the superior weight of a column of cold air over the weight of a similar column of equal height of the hot air enclosed in the chimney. Thus

*Paper read at Liverpool before the Institution of Heating and Ventilating Engineers.

Digitized by Google

the inflowing air is heated and the chimney kept warm by arranging that all inflowing air must pass through the furnace, and so cause the combustion of coal or other fuel, producing enough heat to use most of it to raise steam, and leaving enough to produce the requisite draught. A chimney with natural draught will have a draught dependent upon its height, the power of which will not vary except upon the rise or fall of the internal temperature. It has, therefore, no sucking power—in fact, the term suction in this connection is a fallacy. The chimney acts because the external air is heavier than the internal, and thus presses into the chimney by the only available opening—viz., that at the bottom—the furnace front. The pressure or intensity of the draught fixes the amount of fuel it is possible to burn on a given area of grate. It, therefore, becomes necessary, when it is desired to increase the steaming capacity of a boiler by increasing its coal consumption, to increase the intensity of the draught, and the only way in chimney draught is to increase the temperature of the gases passing up it, or increase the height of the chimney. The first method, of course, means a large amount of waste, and is a very uneconomical arrangement; the second is expensive and unusual. A chimney stack 150ft. high will burn from 15lb. to 20lb. of coal per square foot of grate area per hour under normal conditions, but in wet or foggy weather it will be very much less than this, as the wet air is lighter than the dry, and thus produces less pressure at the furnace (the weight of water vapour is about half that of air).

A fair average of temperature in the furnace is 2,400deg. F., and that of the escaping gases at the chimney without economisers, 600deg. F. This means that one quarter of the total heat generated is sent up the chimney to waste. Thus, on a 2,000-h.p plant, almost 500 h.p. is going up the chimney per hour, and the coal bill necessary to sustain this will come to a big figure in the year. Suppose we could reduce the amount of air accompanying each pound of coal from, say, 24lb. to 12lb. (the chemical requirement), and the temperature kept the same, then we would only send one-eighth of the total power up the chimney, and save one-eighth of the coal bill at the same time. The temperature in the furnace would then be greater, the heat generated greater, and, of course, the temperature of the gases at chimney less. The effect of the draught and the air supply to boilers having been demonstrated to be of such importance, we are brought now to the consideration of the best means of producing the requisite draught, and it is not only the author's contention, but it has become a well-ascertained fact that it is cheaper and better in every way to provide the necessary supply of air for burning fuel in steam-boilers by mechanical means, and to take as much heat out of the hot gases after they have ceased to be in contact with the boiler itself before they are turned out into the atmosphere, than to do it in the older way by utilising a portion of the heat generated to create the necessary supply of air. This is the primary reason for using a mechanical means of moving the air. The heat previously necessary to create the draught by means of a chimney, may now be employed usefully in other directions.

There are several forms of mechanical draught, and perhaps the first step in that direction is the use of steam-jets. These are certainly the most expensive means on an ordinary land installation of Lancashire, Cornish, or water-tube boilers. They may be applied at the fire or in the chimney, as in the case of a locomotive boiler. In the latter case the exhaust steam from the engine is used, and excellent results are obtained. But it is with fan draught that this paper is intended more particularly to deal. Fan draught may be divided into two distinct classes—viz., forced and induced. Forced draught may again be subdivided into two methods—viz., first, closed stokehold; and, second, closed ashpit. The first, or closed, stokehold method is almost exclusively used for shipwork. Here it is possible to entirely close up the stokehold and drive air by means of a fan into it, raising the pressure as shown on an ordinary U-tube water-gauge to about 2in. The only outlet for the air is through the furnaces, and where this method can be adopted it is undoubtedly the best, as a minimum of fan power is required, due to cold air only having to be handled. (It must be remembered that the hot gases leaving a boiler are practically double the volume of the air entering the furnaces, due to expansion from rise of temperature.) The air passes both through the fire from the ashpit and over the fire through the fire-door, the latter assisting largely in preventing smoke.

For land work or stationary boilers, however, this method can scarcely ever be adopted, and if a forced-draught system is desired, the closed ashpit must be resorted to. Here, again, a minimum fan power is required, as cold air is being handled, but there are several disadvantages which, in the author's opinion, far outweigh any saving which might be effected by using the smaller fan, as, for instance: (1) Initial cost of furnace fronts is very high, say £16 per

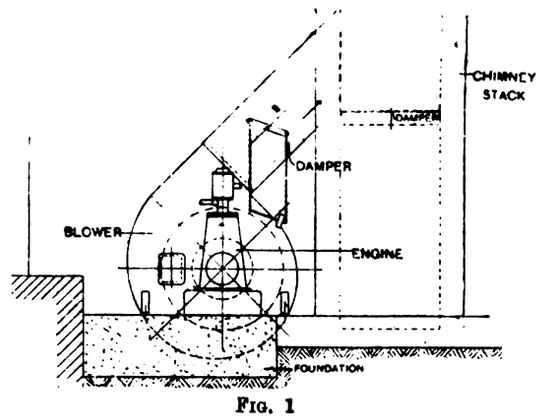

FIG. 1

furnace, and these are frequently needing repair. (2) Fires do not burn so evenly. (3) The air supply must be shut off before the fire-door is opened, or the stoker would run grave risk of being burned through the pressure forcing the heat and flames outwards. (Automatic appliances have been tried, but are not always a success.) (4) The pipes conveying the air to the furnaces are very much in the way, and are usually very unsightly.

In the author's opinion, by far the best method of obtaining draught by mechanical means is the induced-draught system, wherein the fan is placed between the boilers and chimney, or point of discharge of waste products into atmosphere. By such an arrangement the coal consumption may be increased from the 15lb. to 20lb. per square foot of grate in chimney draught to 30lb. to 40lb. per foot

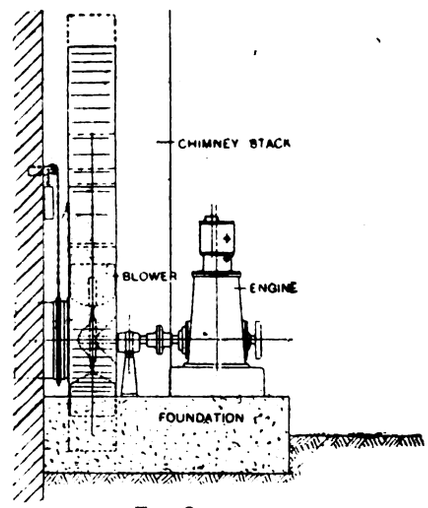

FIG. 2.

under ordinary conditions, and beyond this amount under special circumstances. This results not only in a proportionate increase of steaming capacity in the boilers, but in greater efficiency of combustion, and consequent economy. Most steam-boiler plants nowadays are provided with economisers of the Green's, Lowcock's, or similar type. Where such is the case, an opening is made in the flue between the economisers and chimney, and the fan inlet connected thereto by a short brick or metal flue. Another opening is made in the main flue at a point nearer the chimney, or into the chimney itself, and this opening is connected to the fan outlet in the same way as to the inlet.

Digitized by Google

Between the openings and inside the main flue is placed a damper, so that all gases, after leaving the boilers, must of necessity pass through the fan on their way to the chimney, so long as the aforementioned damper is closed. It is also customary to place dampers both at the inlet and outlet of the fan, so that, by manipulating these two and the one in the main flue, the fan may be cut out, and natural draught resorted to in case of necessity. The same arrangement applies where no economisers are installed, and in such cases the fan handles the gases at the high temperature at which they leave the boilers. Of course, in either case special arrangements must be made in order to keep the bearings cool, either by water-jacketed bearings or an arrangement of air cooling.

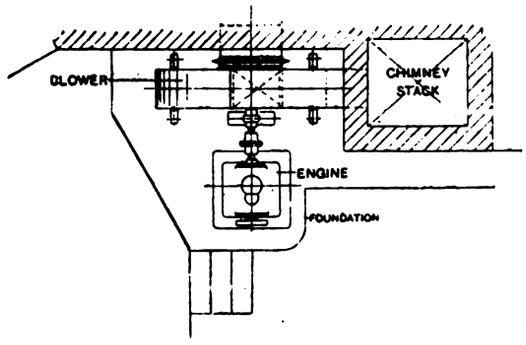

FIG. 3.

Fig. 1, 2, and 3 show respectively front and side elevations, plan, and general arrangement of a cyclone induced-draught plant, such as described and installed by the author's firm in the Manchester district. This is a small installation for two boilers only, as will be seen from the general arrangement (Fig. 4). In this arrangement the main flue was tapped and a connection made to the fan inlet, the fan outlet being connected direct to the chimney as shown clearly in Fig. 1. Instead, however, of putting a damper in the main flue, it was more convenient to place it in the chimney, as shown in Fig. 1, the effect, of course, being the same. The fan in this case is driven by a direct-connected enclosed-type steam-engine, the combination running at about 600 revolutions per minute. The plant was put in for two reasons. In the first place, great difficulty was experienced in keeping steam, and in the second place, the hard firing necessary in the effort to do this naturally resulted in volumes of dense smoke being emitted from the

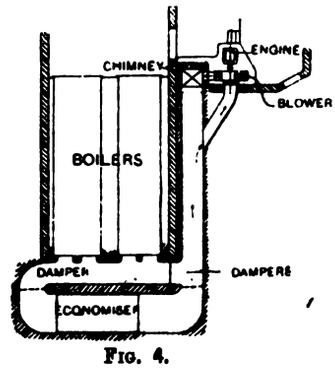

FIG. 4.

chimney stack, for which the firm were prosecuted more than once. The fan enables steam to be kept with ease and has entirely cured the smoke nuisance; only a light smoke can be seen being emitted from the chimney.

Another installation is illustrated by Figs. 5 and 6, which show elevation and plan respectively. In this instance the fan inlet is placed close against the main flue, and again the outlet or delivery is through a connection into the chimney. It will be noticed that the fan shaft goes right through the flue to a bearing on the opposite side. This was necessary as the fan is a large one, and an overhung wheel was not desirable. It is interesting to note the results accruing from this installation. One boiler after another had been added to those put down when the works and chimney were built. As a natural consequence the draught had become totally inadequate, resulting in insufficient steam, and smoke trouble. A new chimney was contemplated, but the proprietors were persuaded to try a fan first. The net results after 12 months' trial were: (1) an ample supply of steam under all atmospheric conditions; (2) a discontinuance of the smoke nuisance; (3) retention of the old chimney, thus saving the cost of a new one; and (4) a saving of exactly 25 per cent. of the year's coal bill, through being enabled to burn an inferior quality of coal. It is, perhaps, worth while to note this saving more than paid for the induced-draught plant in the first year's run.

Still another arrangement is shown by Figs. 7 and 8. This is very similar to the last, the principal difference being in the method of driving. Being a town electric lighting station, the authorities preferred to drive by motor and belt. The very satisfactory results secured by a system

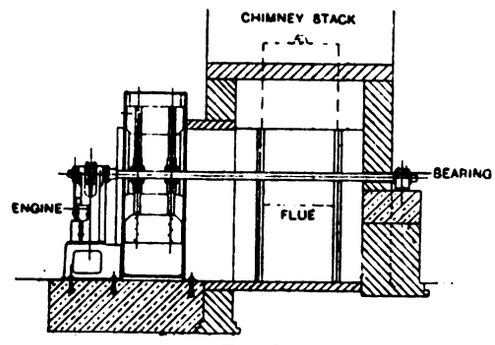

FIG. 5.

of induced draught are due to a less volume of air being required, though at a higher pressure than with chimney draught. A chimney easily works at a vacuum of ½in. to ¾in., while an induced fan is generally arranged to give 1½in. to 2in. In consequence of this, thicker fires can be carried and higher temperatures maintained, resulting in more rapid conduction of heat through the heating surface, and, therefore, a greater economy of heat than with chimney draught. This higher temperature of combustion, and consequent increase of evaporating power of the boilers, is such that usually three boilers with induced draught will do the work of four with chimney or natural draught. Occasionally better results even than these have been secured. One advantage of induced over forced draught is that a better and more even distribution of air is obtained.

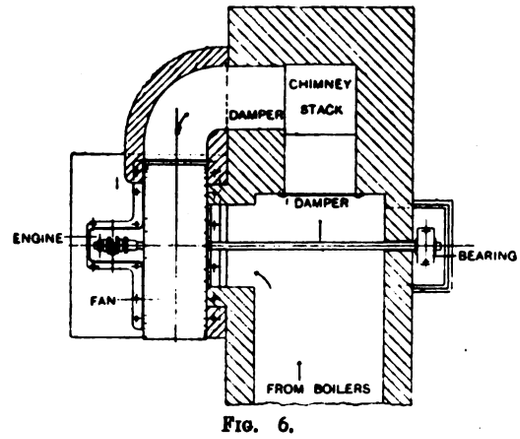

FIG. 6.

One of the best arguments in favour of induced draught is that by it the pressure may be kept practically constant, and consequently the temperature, so that the boiler shell and furnaces do not contract and expand to the same extent, thus saving large sums of money in repair bills for leaky joints and rivets. It is not always possible to keep boilers idle when an induced-draught system is introduced to an existing plant as where one or two boilers may be installed. In such a case an alternative is to reduce the length of the firebars, and by keeping thicker fires to secure the beneficial results already described. One of the most valuable features of an induced-draught apparatus is that it enables the high temperature upon which a chimney depends for its results to be dispensed with. In fact, the more heat abstracted from the gases by economisers and such like apparatus for heating water, air, etc., the better it is for the fan.

Digitized by Google

These are days when profits are made—or, at all events, augmented—by economies at all points, and insufficient attention has been paid in many installations to the possibilities in this direction. Not only may the boiler feed water be heated by economisers, but in works where quantities of hot water are required for manufacturing purposes, such may also be obtained in the same way. And again, in manufacturing establishments, laundries, etc., where hot air is required for drying or similar purposes, this also may be obtained by economiser pipes, just as hot water is. An induced-draught fan renders the plant it is working with quite independent of climatic conditions. A chimney that will just do its work on a clear

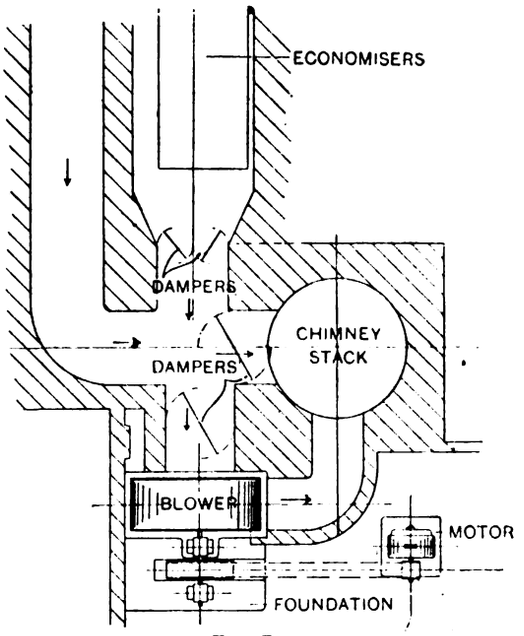

FIG. 7.

cold day may give considerable trouble in damp or foggy weather, but a fan is always positive and alike. It is also more flexible and under control, rendering it capable of answering to sudden calls. In the case of an electric light station, for instance, if a heavy fog comes on there is a big rush for current, and consequent heavy demand on the boilers. If chimney draught has to be depended upon, it will be at its worst under such conditions, but a fan would not be affected by the fog, and would answer at once to the demand made upon it. Again, in consequence of the intensity of fan draught, it is possible where such sudden demands for steam are likely to be made to keep fires banked up and dampered down, and then, when required, to have them in full blast in a few seconds. Another minor

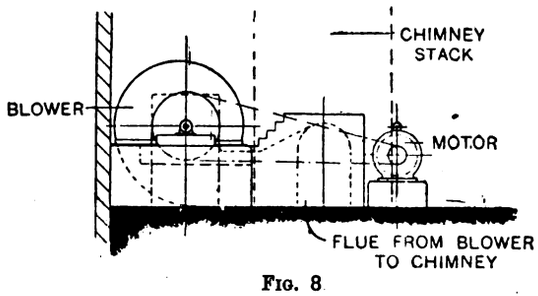

FIG. 8.

advantage in an induced-draught apparatus, especially where a steam-engine is the motive power, is that of automatic control. A very simple device can be arranged so that as steam falls below a given fixed pressure, the speed of the fan is automatically increased and *vice versâ*. Fan draught is a great aid to mechanical stokers—in fact, some forms of stoker cannot be worked without, but depend on the fan for their usefulness.

Reference has already been made to the economy secured by burning cheaper fuel. It is not fully recognised that the calorific value of coal is not at all in proportion to its cost. The lower grades of coal have a calorific valve not a great deal less than the higher-priced qualities. The difficulty with chimney draught is to burn them and thus extract their value. But with fan draught this difficulty is overcome, as, by its aid what has hitherto been termed absolute rubbish and useless can be burned and made to yield its heat units for a useful purpose. Mention has also been made of the value of an induced-draught fan as a smoke preventer. Public authorities are daily increasing their vigilance, and woe betide the firm that belches its black smoke into the atmosphere, polluting all the surroundings. But this is not all. This black smoke, as pointed out earlier in the paper, is unconsumed carbon, and, therefore, waste. So on all accounts it is desirable to stop it. A properly designed and arranged induced-draught plant will accomplish this, as already stated, by increasing the temperature of combustion, and thus make the boiler consume its own smoke, or, to put it another way, by enabling the proper chemical changes to take place in the furnace to obtain immunity from smoke trouble.

A very important point not yet touched upon, and particularly applicable to buildings projected, is the question of the chimney in relation to induced draught. A stack higher than that necessary to carry the gases above the surrounding property, say about 50ft. high, is useless when an induced-draught fan is at work. It, therefore, pays to consider the question of fan *versus* chimney in the matter of first cost, and also as to economy of space. To take a recent installation as an illustration. There are five boilers, with a combined grate area of 190 square feet, and working at a steam pressure of 160lb. The chimney is 120ft. high. It was desired to burn 170 tons of coal per week of 56 working hours, say 31lb. coal per square foot of grate, besides night consumption. One boiler was always idle for cleaning purposes, reducing active grate area to 152 square feet. It was found quite impossible by natural draught to consume the quantity desired, and in making the effort dense volumes of smoke were turned into the atmosphere. For this plant a No. 11 cyclone induced-draught fan was installed, running at 400 revolutions per minute, and capable of handling all the gases from the five boilers, if necessary, at a water pressure of 1·7in, and absorbing 20 b.h.p. The results far exceeded the proprietor's expectations. Instead of volumes of dense black smoke previously turned into the atmosphere, nothing but a thin grey vapour now issues from the chimney top. Two boilers now stand idle, although the 170 tons is easily being burned at the rate of 42lb. per square foot of grate, and more water is evaporated with the three at work than previously obtained with the four. The quality of the coal used has been reduced to one at about 25 per cent. less cost. Suppose this firm had decided to adopt mechanical draught instead of chimney draught in the first instance, the cost would have been about 20 per cent. of that paid for the plant with natural draught. Seeing that the power required to drive an induced-draught fan is only about 1 per cent. of the power of the plant it operates, the cost is of little consequence.

In addition, then, to the many advantages other than financial to be derived from an induced-draught apparatus over chimney draught, there are two outstanding economical features—viz., much reduced first cost, and reduced cost of fuel. In conclusion, I desire to acknowledge my indebtedness to Mr. Snow for some extracts culled from his treatise on "Mechanical Draught," and to the members of our engineering staff for their assistance in the preparation of this paper, which, I trust, may be of some assistance to the members of the institution.

Appended are the results obtained in regard to Lancashire boilers 30ft. × 8ft × 160lb. working pressure under test at Messrs. W. and J. Whitehead's, Laisterdyke, Yorkshire, with induced and natural draught. The boilers were fitted with Proctor's mechanical stokers.

These tests were conducted on behalf of Messrs. Matthews and Yates, Limited. It will be seen that the firms concerned have cause for congratulation on the results of the induced-draught plant, as two boilers are now doing the work that formerly took three, evaporating more water per hour per pound of coal fired and, of course, per square foot of fire grate per hour. The temperature of the feed water was raised 184·4deg. in the economiser as against 137deg. by natural draught, and the temperature of the waste gases was lowered by 172·6deg. as against

Digitized by Google

115deg. by natural draught, thus utilising more of the available heat. The nuisance resulting from dense volumes of smoke being emitted from the chimney, in the forcing of the boilers, and hard firing necessary under natural draught, was entirely cured, only a light smoke being visible at the chimney top. It may be noted that the test was made with coal of exactly the same quality, although the coal formerly used was 3s. per ton dearer than that tested, the saving in the coal bill on a weekly consumption of 170 tons being about £25. 10s., or about 25 per cent. on an average, easily. The difference in the weight of ash and clinker is worthy of notice, and it should be mentioned that in the induced-draught test the fan was working three boilers, although only two were being tested. This was owing to the fact that the third boiler was being used for heating purposes, and working at 80lb., and was not fed with the same water as the boilers for running the main engines.

LEGAL INTELLIGENCE.

PROMOTION OF THE GENEVA TRAMWAYS.

The action brought by Chaplin, Milne, Grenfell, and Co., Limited, against L. Hirsch and Co., Limited, in which the plaintiffs, pleading misrepresentation, claimed rescission of an underwriting contract in connection with the promotion of La Compagnie Genevoise des Tramways Electriques, and also the repayment with interest of £250,000 subscribed by the plaintiffs, occupied Mr. Justice Warrington some days. The defendants denied misrepresentation.

Mr. Levett, K.C., Mr. Astbury, K.C., and Mr. D. Pollock (instructed by Messrs. Bompas, Bischoff, and Co., of 4, Great Winchester-street, E.C.) appeared for the plaintiffs; and Mr. Rufus Isaacs, K.C., Mr. Ralph Neville, K.C., Mr. Martelli, and Mr. H. Goldberg (instructed by Messrs. Goldberg, Barrett, and Newall, of 2, West-street, Finsbury, E.C.) represented the defendants.

On behalf of the plaintiffs it was stated that they were induced to enter into the contract on the strength of a circular letter they received from the defendants in November, 1900, which, they alleged, misrepresented the earnings of the old company. It was also alleged that statements made by Mr. Neumann, a member of the defendant firm, as to the position of the tramways company were misrepresentations.

Evidence was given on behalf of the plaintiffs by Mr. A. M. Grenfell, Mr. G. D. Milne, Mr. Ernest Chaplin (directors of the plaintiff company), and other witnesses. In the course of his evidence **Mr. A. M. Grenfell** denied that it was a subject of common conversation that the earnings were insufficient to pay the debenture interest in July, 1901.

For the defence, **Mr. Ludwig Neumann** denied all misrepresentation, and stated that the basis of the contract was a favourable report on the undertaking by Mr. Field, a tramway expert.

His Lordship, delivering judgment on Tuesday, observed that though the plaintiffs' claim was based on alleged misrepresentations, they stated emphatically that those misrepresentations were not fraudulent, that they were innocently made, but that, though innocently made, were sufficient ground for the rescission of the contract said to have been induced by them. In the first instance, when the action was started on May 12, 1903, and the statement of claim delivered in June, 1903, the only representations complained of were contained in the letter of Nov. 16, 1900, and it was not until a year later, in May, 1904, that the statement of claim was amended. In that amended claim there were inserted allegations that the defendants, by one of their partners, Mr. Ludwig Neumann, had made certain parole misrepresentations as to the earnings of certain tramways, and plaintiffs then, for the first time, added that claim founded on parole misrepresentation to the case previously made. The case was more remarkable from the fact that as it developed it turned out that that representation was in reality that on which plaintiffs' claim was based, and the only real question that he had to determine was whether the parole representation was in fact made. It was obvious that at the time of the interviews between Mr. Neumann and the plaintiffs it was well known that the earnings of the tramways were wholly insufficient to pay the £38,500 required for debenture interest. It was said that at these interviews Mr. Neumann told the gentlemen there assembled that the net earnings of the three undertakings then in operation (two other lines having been amalgamated with the original concession) were sufficient to provide the £38,500, and plaintiffs said that statement was the determining factor in their minds, and that, unless they had been assured that the existing undertakings were earning enough to pay interest on the debentures, leaving the profits expected to be realised by the electrification of the system to go to paying dividends on the shares, they would not have gone into it at all. Nothing was settled at the first meeting, and at the second meeting Mr. Bousquet, who had been in Geneva, attended with Mr. Neumann. It was said that Bousquet repeated the statements as to the debenture interest; but the plaintiffs' witnesses all seemed to have a different impression as to what Bousquet said. At the third meeting Mr. Burns (of J. S. Morgan and Co.) attended, and he also said that Mr. Neumann stated to him that the earnings were sufficient to pay interest on the debentures. His evidence was confirmed by other witnesses. As a consequence of that interview, plaintiffs determined to go into the transaction, and on Dec. 18 Messrs. Hirsch wrote a letter which purported to record the effect of the negotiations and the contract into which plaintiffs desired to enter. The tramways were worked, but suffered from various untowards circumstances, with the result that the debenture interest was not earned, and no issue was made to the public, the underwriters taking up the debentures. During 1901 the weekly returns of the tramways were sent to plaintiffs, and in the middle of 1901 a balance-sheet for 1900 was sent to them. Mr. Arthur Grenfell admitted seeing these, and also tabular statements comparing the weekly receipts for 1900 and 1901. If he had examined the returns, even in the most cursory manner, he must have seen that the net earnings for 1900 could not have been anything like £38,500. He said he trusted to Mr. Neumann's word, and did not look at the returns to see if Neumann's statement was true. It was very difficult to understand that. The statement that had been made was, according to him, the very basis of the transaction. On March 23, 1903, the plaintiffs wrote to the defendants complaining that the representations made to them were untrue; but it was not until April, 1904, that plaintiffs gave notice that they intended to rely on the alleged statement of Mr. Neumann as to the earnings in 1900 being sufficient to pay interest on £850,000 debentures. That was the most serious matter of all, because if it were true that the statement was made, it was not disputed that it was untrue. More than that, it would be absurdly untrue. He had seen Mr. Neumann in the witness-box and watched him carefully, and he had not the least hesitation in saying that not only he, but every person in court, must have been convinced that he was telling the truth, and not only telling the truth, but that he was a man who would be incapable of making a fraudulent statement such as that which, in reality, although not in terms, he was accused of making. He therefore found as a fact, on the consideration of the evidence that had been adduced, that Mr. Neumann did not make the statement which he was alleged to have made. The witnesses for the plaintiffs must have given their evidence under some misapprehension.

Judgment for the defendants, with costs.

EDISON AND SWAN UNITED ELECTRIC LIGHT.

The petition of the company was heard by Justice Buckley for the reduction of its capital by writing off £58,910.

Mr. Macnaghten, K.C., explained that the company was formed in 1885, and since 1901 no dividends had been paid, and large sums had had to be written off the capital in consequence of losses. The business was that of manufacturers of lamps and appliances for the purposes of electric lighting, and in regard to which three valuable master patents had now expired.

His Lordship sanctioned the reduction, and directed its advertisement for three months.

COMPANIES' MEETINGS AND REPORTS

DIRECT UNITED STATES CABLE.

The ordinary general meeting of the Direct United States Cable Company was held at Winchester House on Tuesday under the presidency of Mr. E. M. Underdown, K.C.

The **Chairman** stated that the revenue for the six months to June 30,

Digitized by Google

after deducting disbursements, amounted to £43,121, while the working and other expenses, including income tax, but exclusive of the cost of cable repairs, absorbed £21,185, leaving a balance of £21,936 as net profit, making, with the amount brought forward from the previous half-year, £2,479, and, with £1,966 compensation received on surrender of the lease of premises at New York, a total of £26,381. The whole result of the financial year's working was as follows: receipts, £92,902, less expenses and other ordinary payments, £43,002; £36,426 had been paid in dividends and £14,000 had been placed to reserve. The cables were in very good condition and working entirely satisfactorily. He concluded by proposing the adoption of the report and accounts and the payment of a final dividend of 3s. a share, free of income tax, making, with the interim dividends already paid, a total distribution of 3 per cent. for the year ended the 30th ult.

Sir James Pender, Bart., seconded the resolution, which was carried unanimously.

NATIONAL TELEPHONE.

The general meeting of the National Telephone Company, Limited, was held last Friday, Sir Henry Fowler, M.P., the chairman, presiding. Particulars of the report were published in our issue of the 15th inst.

The **Chairman** remarked that the half-year under review—*i.e.*, to June 30—had been a record one. There had been an increase of revenue of £90,016, and the working expenses had increased by £57,000. The net result, after taking off the Post Office royalties, amounting to £90,702, was a balance of £326,825 as compared with £303,000 in the corresponding half of last year, being an increase of net income of £23,668. About 9,200 new customers were added during the period, and 9,700 were now waiting to be put on, representing a new income of £53,000 a year. The messages sent last year were 938,000,000, a large increase, the average receipts for each message being less than ½d. He expressed the belief that the Postmaster-General would credit the directors with a desire to meet him in a fair spirit, and he hoped the negotiations for the taking over of the business would result in a satisfactory arrangement being arrived at.

The report was adopted.

EDMUNDSON'S ELECTRICITY.

The seventh ordinary general meeting of Edmundson's Electricity Corporation, Limited, was held on the 21st inst. at the Westminster Palace Hotel, Mr. Francis E. Gripper, M.I.E.E., chairman and managing director, presiding. Particulars of the report were given in our issue of the 15th inst.

The **Chairman** remarked that he was glad to be able to report continued satisfactory progress. Established seven years ago for the purpose of working a considerable number of electric lighting undertakings, the Company was now reaching the end of what might be termed the construction stage. Since the last meeting the Company had completed electric lighting works at Caterham, Glossop, Berwick, Ryde, Surbiton, Frome, and Dorking, and had completed and opened electric tramways at Glossop and Scarborough. At Newbury the lighting works were almost completed, and would be opened in a few weeks. Good progress had been made in connection with the Lancashire electric power station, which would probably be opened early next year. With the exception of two towns, the Company would then have the whole of their works opened and running. The two exceptions were Ramsgate and Inverness, for which, after many attempts, the Company had recently obtained the necessary parliamentary powers. It was not the intention of the directors to seek for further powers, except such as might be necessary for the Company's existing undertakings, as the Company would have ample scope in the development of the undertakings it was now interested in. The rapid expansion of the various undertakings is shown by the lamp connections, which during the year increased from 335,000 to 568,000, and have since increased by another 65,000 connected or applied for during the past three months. During the past year the issue of new capital had been necessarily heavy to meet the expenditure on the new works and the extensions required in the older works, and 20,000 preference shares, 20,000 ordinary shares, and £92,000 of debenture stock had been issued. The necessity for raising so much new capital at a time when market conditions were unfavourable for all issues had given the directors much cause for careful consideration, but the requisite capital had been obtained on reasonable terms. The Company's capital requirements for the future would be on a less extensive scale The chairman concluded by moving the adoption of the report and accounts.

Mr. W. R. Davies seconded the motion.

The resolution was carried unanimously.

On the motion of **Mr. Davies**, Mr. H. Wolfenden's election to a seat on the Board, through the resignation of Mr. J. R. Wigham on account of failing health, was confirmed.

Mr. W. R. Davies was re-elected a director of the Company, and a vote of thanks to the chairman and directors terminated the proceedings.

EASTERN TELEGRAPH.

The half-yearly meeting of this Company was held last week at River Plate House, London, Sir J. Wolfe Barry presiding. Particulars of the report appeared in our last issue.

The **Chairman** announced in the course of his address that the directors intended to utilise wireless telegraphy. Though they considered that wireless telegraphy would not compete with long-distance submarine telegraphy, the directors were of opinion that there were places where wireless telegraphy could be usefully employed. An example was afforded by the Azores, where the cables of some of the associated companies touched. It was desired by Portugal that some of the outlying islands should be placed in telegraphic communication. Owing to the nature of the bottom, and the landing place of these islands, it was not considered a suitable place to make the connection by cable, neither would the traffic warrant an expenditure on this account. They, therefore, intended to connect the points by a system of wireless telegraphy, to be worked in connection with their cable system.

The report and accounts were adopted.

CHILI TELEPHONE.

The fifteenth ordinary general meeting was held at Winchester House, Mr. George Keith presiding. Particulars of the report appeared in our issue of the 15th inst.

In the course of his remarks, the **Chairman** stated that during the year an additional circuit had been put up between Santiago and Valparaiso, and several provincial offices had been opened.

The report was adopted.

ANGLO-AMERICAN TELEGRAPH.

The report for the half-year ended June 30 last, to be presented at to-day's meeting, states that the total receipts, including the £1,128 brought forward, amounted to £165,614. The traffic receipts show a decrease of £13,280 compared with the half-year ended June, 1903. The total expenses, including the repair of cables, etc., amounted to £63,578, being a decrease of £2,314. The directors have, before declaring the net profits, set apart £12,000 to the renewal fund, leaving a balance of £90,035. Quarterly interim dividends of 12s. 6d. per cent. on the ordinary stock and of £1. 5s. per cent. on the preferred stock were paid on April 30, 1904, absorbing £43,750, and second quarterly interim dividends of 12s. 6d. per cent. on the ordinary stock and £1. 5s. per cent. on the preferred stock, amounting to £43,750, will be paid on July 30. The balance of £2,535 will be carried forward. A scheme of pensions for employés of the Company, in lieu of the present system of endowment assurance, has been prepared by the directors, and will be submitted to the stockholders for approval.

METROPOLITAN RAILWAY.

The report for the half-year ended June 30 states that the works required for the electrification of the line have proceeded rapidly during the past six months, and that in the course of a short time the testing of the machinery and plant under normal conditions of working will take place. Thirteen trains of new corridor cars have already been constructed and are being electrically equipped at Neasden. The rest of the rolling-stock necessary for the new system of working is in course of construction at Manchester and Birmingham. The Harrow and Uxbridge Railway was opened for public traffic on July 4, and is being worked by the Company under the statutory agreement. The directors recommend a dividend upon the ordinary stock at the rate of 3 per cent. per annum. A resolution will be submitted to a special meeting providing for the creation of the capital authorised by the Metropolitan Railway Act, 1904.

NEW COMPANIES REGISTERED.

Haste Pump Company, Limited.—Capital, £100,000. Objects: to adopt an agreement with F. C. Haste and C. W. Milne for, *inter alia*, the carrying on of the business of mechanical and electrical engineers, electroplaters, galvanisers, etc.

Public Undertakings, Limited.—Capital, £10,007. Objects: to acquire, *inter alia*, the benefits of and rights of the promoters under the Bishop Auckland, Shildon, and Spennymoor Tramways Order, 1904, to adopt an agreement with the United Kingdom Tramway, Light Railway, and Electric Syndicate, Limited, and to carry on the business of steam, electric, or horse tramway and railway proprietors and lessees, etc. Registered office: 28, Victoria-street, Westminster.

Davies, Kent, and Stewart, Limited.—Capital, £3,500. Objects: to acquire the business carried on as Davies, Kent, and Stewart, and to carry on the business of manufacturers of electrical accessories, flexible wire makers, electricians, suppliers of electricity, etc. No inital public issue. Registered without articles of association.

Electrical Bleaching Company (1904), Limited. — Capital, £75,000. Objects: to adopt five agreements, one with the Electrical Bleaching Company, Limited, three with C. E. W. Gaddum, and one with J. J. Graham, and to carry on the business of bleachers, dyers, electricians, electrical engineers, suppliers of electricity, etc. Registered office: 196, Deansgate, Manchester.

Liens Registered.

Blackheath and Greenwich District Electric Light Company, Limited.—Trust deed, dated June 3, 1904, to secure debenture stock to an amount not exceeding the paid-up share capital from time to time, and being supplemental to a deed of Aug. 3, 1900, securing £120,000 debenture stock, has been registered. The present deed is stamped to cover £30,000 (making a total of £150,000 covered by stamped duty). Property charged: the company's undertaking and property, present and future, including uncalled capital, and the undertaking of the Crystal Palace District Electric Supply Company Limited, which the company undertake to complete the purchase of. Trustees: H. R. Beeton, 18, Austin-friars, E.C., and W. R. Davies, 10, Moorgate-street, E.C.

Bath Electric Tramways, Limited.—A charge for a sum not exceeding £10,000 has been registered in favour of the Union of

Digitized by Google

London and Smith's Bank, Limited, secured on certain undertakings authorised by various orders, land in Bath, and the property, assets, and effects, including the purchase money which may be realised by the sale of the undertakings and certain debenture stock.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Newcastle-upon-Tyne.—The Guardians invite tenders for the installation of the electric light in the hospital block at the workhouse. Specifications may be seen at the offices of Messrs. Newcombe and Newcombe, 89, Pilgrim-street, Newcastle-upon-Tyne. Tenders by 12 noon on Aug. 4.

Plymouth.—The Corporation invite tenders for (25) steam alternator, etc.; (26) Lancashire boilers, with mechanical stokers; steam, exhaust, and other piping; ejector, condenser, valves, etc. Specifications, etc., may be obtained from the Borough Electrical Engineer. Tenders by Aug. 15.

London, S.E.—The Bermondsey Borough Council invite tenders for the wiring of the staircases and courtyards of the Fulford-street dwellings. Specifications, etc., may be obtained from Mr. Fredk. Ryall, town clerk, Town Hall, Spa-road, S.E. Tenders to be delivered at the Town Clerk's Office by Aug. 8.

Hapton (Lancs.).—Tenders are invited for the street-lighting of the parish of Hapton for eight months, commencing Sept. 1 and ending April 30, 1905; also tenders for same period during years 1905, 1906, and 1907. Tenders to Mr. Ed. O'Shaughnessy, clerk to the Hapton Parish Council, 16, Hammond-terrace, Padiham, by July 30.

Leeds.—The Corporation invite tenders for the supply of two 1,000-kw. turbo-alternators, with condensers, exciters, and high and low tension switchgear for same. Forms of tender, etc., can be obtained from Mr. J. B. Hamilton, general manager, Standard-buildings, City-square, Leeds. Tenders to the Town Clerk by 10 a.m. on Aug. 15.

Dover.—The Corporation invite tenders for the supply and erection of one surface-condenser air-pump, two centrifugal pumps, and pipework, to heat 10,000lb. of steam per hour and to give a vacuum of not less than 28in. Specifications, etc., may be obtained on application to Mr. L. W. Woodman, borough electrical engineer, Park-street, Dover. Tenders by July 30.

Beverley.—The Visiting Committee invite tenders for various work in connection with the provision of new fire appliances at the asylum, including internal electric fire-alarm communications. Specifications, etc., may be obtained on and after 25th inst. at the office of Messrs. Maxted, Knott, and Coles, engineers, Burnett-avenue, High-street, Hull. Tenders by 12 noon on Aug. 10.

Penang.—The Municipal Council of George Town, Penang, invite tenders for the supply and delivery of tramcars, complete with motors, controllers, trolleys, etc. Specification, etc., can be obtained at the offices of Messrs. Preece and Cardew, 8, Queen Anne's-gate, Westminster, S.W. Tenders to Mr. R. M. Christie, 4, East India-avenue, London, E.C., by 12 noon on Aug. 24.

Perth.—The Corporation invite tenders for the construction and equipment of about 4¾ miles of route length of tramways, constructed as single line with passing places—viz.: (1) permanent way and paving, including copper bonding; (2) overhead equipment; (3) cables, ducts, etc.; (4) cars and equipments; (5) car depôt building. Specifications, etc., can be obtained from the Town Clerk. Tenders before noon on Aug. 16.

Greenwich.—The London County Council invite tenders for the manufacture, delivery, and erection at the tramways electricity generating station at Greenwich of the following plant: two 24in. centrifugal pumps and motors, one 3in. centrifugal pump and motor, two 8in. by 8in. three-throw air-pumps and motors, one 3in. artesian well pump, fixed and rotary strainers, etc. Specifications, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 4.

Manchester.—The Directors of the Manchester Dock and Warehouse Extension Company, Limited, invite tenders for the wiring (for power and light) and electric lighting of five transit sheds (now in course of erection) on the southerly side of dock No. 9, in the county borough of Salford. Specification, etc., can be obtained at the office of Mr. W. H. Hunter, chief engineer to the Manchester Ship Canal Company, 41, Spring-gardens, Manchester. Tenders to Mr. F. A. Eyre, secretary, Manchester Ship Canal Company, 41, Spring-gardens, Manchester, by 10 a.m. on Aug. 30.

Australian Commonwealth.—Tenders will be received at the office of the Deputy Postmaster-General, Hobart (Tasmania), until noon on Sept. 30, 1904, for the supply and delivery at the General Post Office, Hobart, of one multiple metallic branching switchboard. Specifications may be seen at, and tender forms and conditions obtained from, the General Post Offices at Hobart, Melbourne, Sydney, Adelaide, Brisbane, and Perth. Tenders should be endorsed "Tender for Switchboard," and addressed to the Deputy Postmaster-General, Hobart. Tenders may be deposited in the tender-box at the General Post Office, Hobart, or, if sent by post, must be prepaid and registered. Tenderers must state the name of the country in which the switchboard will be manufactured.

Reichenberg (Austria Hungary).—The project for the establishment of a central distributing electric power and light plant in the Reichenberg land district has taken definite form. The territory included is about 10 miles square, and 24 towns and villages have joined in the movement and subscribed to the capital stock. Some 10 more are expected to join. The population of the district, exclusive of Reichenberg, is about 60,000. Stock is subscribed at present to the amount of £40,000, and this it is proposed to increase to £80,000. The principal purpose of the corporation will be the distribution of electric light and power, with the possibility of installing and working a system of suburban electric tramways. Tramway and light franchises for the city of Reichenberg are at present owned by private corporations, and at their expiration it has been generally supposed that the city would take over and conduct the enterprises. Negotiations are pending, however, which may change the situation in this respect. Communications regarding equipment, etc., may be addressed to directors Alfred Ginskey, Maffersdorf, and Dr. Richard Pirkl, Reichenberg.

RESULTS OF TENDERS.

Exeter.—The Corporation have accepted the tender of Bruce Peebles and Co., Edinburgh, at £1,050, for the tramway generating plant.

London.—We learn that the order for the electric lighting of the new War Office has been awarded to F. A. Glover and Co., Limited.

Thorne (Yorks.).—The Parish Council have accepted the tender of the Thorne Gas Company, Thorne, at £112. 11s. 6d., for lighting the town.

Rochdale.—The Corporation have accepted the tender of W. A. Peter and Sons for the erection of increased building accommodation at the electricity works.

Radcliffe.—The Urban District Council have accepted the tender of Messrs. Etheridge and Clark, 10, Norfolk-street, Manchester, for the construction of the permanent way.

Radcliffe.—The District Council have accepted the tender of Etheridge and Clark, at £7,930. 6s. 11d., for the construction of the tramway track. The lowest tender was £7,910. 1s. 6d., and the highest £12,660. 0s. 5d.

Whitby.—The Urban District Council have received the following tenders for distributor and street-lighting cables:

Simplified Underground Conductor Company	£971
British Insulated and Helsby Cables	717
St. Helens Cable Company	702
Union Cable Company	689
Glover and Co.	689
Henley and Co.	678
Siemens Bros. and Co.	669
Western Electric Company	658
Callender's Cable Company (accepted)	648

For network and service boxes the tender of the Cable Accessories Company, amounting to £97 (the lowest received), was accepted.

London.—The Metropolitan Asylums Board have received the following tenders for an installation of fire-alarms at the Darenth Asylum:

P. Dewhirst, 24, Birley-street, Blackpool (accepted)	£320	5	0
Donnison, Sillem, and Co., 116, Great Portland-street, W.	400	0	0
Jackson Bros., The Broadway, Plaistow, E.	403	10	0
Electrical Engineering and Maintenance Company, 5, Eastcheap, E.C.	420	0	0
National Telephone Company, Limited, Salisbury House, London-wall, E.C.	440	10	0
Baxter and Impey, 54, Dudley-street, Birmingham	459	0	0
Lea, Son, and Co., Pengwerne Works, Shrewsbury	497	0	0
H. G. Rider and Co., 27, Chancery-lane, W.C.	500	0	0

BUSINESS NOTES.

LIGHTING AND GENERAL.

York.—The extensions of the electric lighting plant on Foss Island were formally opened on July 18.

Ravensthorpe—The District Council have decided to apply for a provisional order for electric lighting.

Leicestershire and Warwickshire Electric Power Bill.—This measure has received the Royal assent.

Metropolitan Electric Supply Co.—An interim dividend of 9s. is declared on the ordinary shares, being at the rate of 9 per cent. per annum.

Dunstable.—The Council have received notice from a supply company of their intention to apply for a provisional order for lighting within the area.

Westminster Electric Supply Co.—The directors have declared an interim dividend for the half-year ending June 30 at the rate of 13 per cent. per annum.

Wrexham.—The Local Government Board have sanctioned the borrowing of £5,600 for the purpose of extending the electric light works and cables of the Corporation.

Deptford.—The Borough Council have decided that no further action be taken with reference to the electric lighting and maintenance, at the public expense, of clocks in the borough.

Radstock.—The Western Electric Distributing Corporation have notified the Urban District Council of their intention of applying for a provisional order for lighting Radstock.

Nantwich.—The Urban Council have received notice from Mr. G. Vaughan Fowler announcing his intention to apply for a provisional order for the electric lighting of Nantwich.

Shardlow.—The Rural District Council have received notice of the application by T. Hooley, Limited, of Sandiacre, for a provisional order to set up electric lighting works in Sandiacre.

Cleethorpes.—The Urban District Council have resolved to apply to the Board of Trade for a further extension of one year in connection with the Council's electric lighting provisional order.

Southampton - Portsmouth.—The Postmaster-General hopes shortly to be able to proceed with the construction of an additional telephonic circuit between Southampton and Portsmouth.

Hampstead.—The Borough Council have approved the decision of the London County Council to apply to Parliament for powers to enable local authorities to wire and fit consumers' premises for lighting.

Iceland.—According to reports in the daily Press, the long-dismissed telegraphic communication between Denmark and Iceland is about to be realised, the initiative being taken by the Great Northern Telegraph Company.

Aylesbury.—The Rural District Council have received notice from the Aylesbury Electric Supply Company of their intention to apply for a provisional order to supply electricity within the rural district of Aylesbury.

Newcastle Electric Light Co.—The directors have declared an interim dividend of 7 per cent. per annum for the half-year ending June 30, which is the same rate as that paid by the company for the last six years.

Hexham.—The Examiners of Standing Orders in the Commons have passed the Electric Lighting Confirmatory Bill, which has been ordered for second reading. The measure has already passed through the Upper Chamber.

Houghton-le-Spring.—The Examiners of Standing Orders in the Commons have passed the Electric Lighting Confirmatory Bill, which has been ordered for second reading. The measure has already passed through the Upper Chamber.

Bombay.—It is reported that there will shortly be a great demand for electric ventilators and other electrical apparatus in Bombay, as a generating station is being erected by the Municipality for the distribution of electric light and motive power.

Haywards Heath.—The Urban District Council have decided "in principle" to take the necessary steps to obtain powers to generate and supply electricity for lighting, traction, and other purposes within the area of their district and in the neighbourhood.

Cork.—The Cork Gas Company and the Cork Electric Tramways and Lighting Company are displaying some rivalry in regard to the illumination of the Carnegie free library. The electric company offers, in the public interest, to carry out the installation free.

Mirfield.—In regard to the electric lighting scheme, the District Council have decided to apply for sanction to borrow £5,000 for the laying of the cables in the district, plans for which have been prepared. The Council will not necessarily spend the whole amount in the first instance.

St Pancras.—A recommendation was submitted at Wednesday's meeting of the Borough Council that application be made to the London County Council for sanction to a loan of £10,000 for electric lighting purposes. Twenty-five fresh applications for the supply of light or power have been received.

Boiler Feed Purifiers.—We are informed by the Paterson Engineering Company, Limited, that they have recently received orders from Messrs. Babcock and Wilcox, Limited, Messrs. Edwin Danks and Co., Limited, Messrs. Belliss and Morcom, Limited, and the borough of Ealing electricity works for their boiler feed purifiers.

County of London Electric Supply Co.—The directors have declared an interim dividend on the ordinary shares for the past half year at the rate of 4 per cent. per annum. The amount of electricity sold in the company's London districts during the half year is estimated to realise £59,338, which compares with £49,854 for the corresponding period last year.

Fulham.—In reference to the note published in our issue of the 15th inst. a recommendation was submitted at the last meeting of the Borough Council that the first section of the scheme prepared by Mr. A. J. Fuller, the engineer, for the extension of the electric lighting undertaking, be authorised. This had been passed by the Finance Committee, the cost being put at £52 000.

Alton.—The Southern District Electricity Corporation, 66, Victoria-street, Westminster, and the Alton and District Electric Supply Company, Limited, have given the Urban District Council notice of their intention to apply for a provisional order in respect of the urban district of Alton. The Council have instructed the clerk to submit a number of questions to the parties before taking any further action.

Norwich.—The Corporation have agreed to amend the agreement with the National Telephone Company with reference to placing telephone wires underground. Originally it contained a clause for the purchase of the exchange system from the company, but the latter now took exception to it and wanted the clause to be limited to the conduits and manholes in the streets, to which the Corporation have now consented.

Leek.—The Urban District Council have resolved that the extension of the cable for lighting Ball Haye Hall and the Derby-street extension be carried out by three single cables laid solid, to be ordered from Callender and Co. It has also been decided to communicate to the Local Government Board, in reply to their letter as to the proposed extension of cables, for which a loan is required, particulars of the work contemplated.

Trowbridge.—The Bill containing the electric lighting provisional order promoted by the Western Electric Distributing Corporation, which has already passed through the House of Lords, came before the examiners of the House of Commons last week for proof of compliance with Standing Orders. Formal proof having been given, the examiners

Digitized by Google

decided that the Standing Orders had been complied with, and the Bill was allowed to proceed.

Ilford.—The annual report to March 31 states that 2,105,788 units were generated. 421,568 were used for public lighting, private consumers took 655,802 and the trams 563,464. The quantity used on the works amounted to 214,170, leaving 250,784 units unaccounted for. The number of public lamps totalled: arc, 57 (10 and 13 amperes); incandescent, 892 (25 c.p.). The total maximum supply demanded was: lighting, 832 kw.; traction, 250 kw.

Blackheath and Greenwich District Electric Light Co.—Letters of allotment for a further £30 000 4½ per cent. first mortgage debenture stock and a further 30,000 7 per cent. cumulative preference shares of the Blackheath and Greenwich District Electric Light Company, Limited, have been posted. Both issues were over-subscribed by the company's shareholders and debenture stockholders, the preference shares being very largely over-subscribed.

Insurance.—The Associated Fire Offices have issued a set of revised rules for electromotors used in textile and corn mills and other buildings where motors are exposed to dust. The essential difference between these rules and those which they supersede is that the new rules allow unprotected ventilating openings in the metal covers of induction motors, provided the superficial area of each such opening does not exceed ¼in. and provided the openings are ⅛in. apart.

St. Marylebone.—At yesterday's meeting of the Borough Council the Finance Committee reported the receipt of a letter from the London County Council in reference to the terms of the advance of £1,415,000 for the electric lighting undertaking. The Finance Committee express the opinion that the terms offered by the County Council are very generous, and intimate that they have been formally accepted by the town clerk in accordance with previous instructions.

Huddersfield.—The engineer's report shows that the number of consumers to date is 1,931, and that 50 lamps had been connected since June. During June, 94,292 units were metered as compared with 91,640 in the corresponding period last year. The report also shows that compared with the month of January, July showed an increase of 44 consumers, 1,354 connected lamps, and 42,815 metered units. On July 1 the total length of mains was 85,551 yards primary and 61,452 yards secondary.

Keighley.—The sale of electricity for June increased by 3,829 units as compared with June, 1903, the actual amount sold being 10,646 units as compared with 6,817 units. From July 1, 1903, to June 30 of this year, 184,307 units were sold as compared with 137,721 in the corresponding period of twelve months ago—an increase of 46,586 units, equal to 33·8 per cent. The Electricity Committee propose to lay 80 yards of cable in Parker-street for the supply of electricity for power purposes to Messrs. Smith and Paget's works.

Chester-le-Street.—The Rural District Council have received a letter from the County of Durham Electrical Power Distribution Company, Limited, stating that they intend making application for a provisional order authorising them to supply electrical energy within the district. It was resolved to oppose the application on the ground that the County Council are expected to undertake a scheme for lighting the whole shire. The Rural District Council have not, apparently, taken any steps in connection with the electric lighting order granted to them.

Ripon.—At the monthly meeting of the City Council it was reported that notices had been received from three companies of their intention to apply for electric lighting orders for the city; while the Power and Traction Company, Limited, having got their Tramway Bill through Parliament, were applying to have the electric lighting order of the Ripon Corporation cancelled. A councillor expressed the opinion that electric lighting would not pay in Ripon unless there was a large increase in population. The matter was deferred for further consideration.

Bath.—In order to meet several applications for a reduction in the charge for current used during the hours of daylight, the Town Council have decided that current be supplied for lighting purposes from Sept. 1 to March 31 between the hours of 9 a.m. and 4 p.m., and between April 1 and Aug. 31 between the hours of 6 a.m. and 6 p.m., at 2½d. per unit, and that special two-rate meters be issued to consumers upon application at the following rentals: 15 lights, 10s. per quarter; 30 lights, 12s. 6d. per quarter; 60 lights, 15s. per quarter; 120 lights, 20s. per quarter.

Melbourne.—The materials for the electric lighting of the Melbourne express have arrived, and it is expected that the cars will be equipped shortly. The commissioners recently had their own inspection car and another fitted with the Maxim-Vickers electric lighting system for trial purposes, and the results gave satisfaction. The system adopted for the express cars is that made by Messrs. Stone and Co., of England, which is at present in use on thousands of cars in Great Britain, and which has met with the approval of the railway companies.—*N.S.W. Railway Budget.*

Tenbridge.—The following is a statement of electricity generated and sold during the year to March 31: current generated, 128,679 units; public lamps, 36,810; private consumers, 47,389; quantity used on battery, 14,260; used on mains, 4,139; used on works, 26,081; total units sold, 84 199; total used at works, 44,480; works cost per unit, 2·766d.; total cost per unit (omitting capital charges), 3·711d.; average price obtained, 3·9d. per unit; price charged for motive power, 2 0). per unit; deficit chargeable to general district rate, less gross profit of £156. 9s. 1½d., £1,280. 9s. 2d.

Camberwell.—The Borough Council have granted an application from the Postmaster-General for consent to the placing of an underground telegraph line along the south side of Chadwick-road, and another from the fire station in Peckham-road to the corner of Rye-lane, thence along the west side of Rye-lane to and under the London, Brighton, and South Coast Railway Company's arch; also from the corner of High-street and Rye-lane along the south side of High-street to opposite the towing path, and from thence across High-street and along the towing path to a point near the Grand Surrey Canal.

Northfleet.—The Urban District Council have three suitors for the privilege of supplying electric current to that town. In addition to the Gravesend Corporation, notices have been received from Messrs. Foote and Milne, Limited, of Victoria-street, London, and the Kent Electric Power Syndicate. The Council themselves have an electric lighting order, and the Board of Trade have enquired what steps are being taken to carry it into effect. An agreement for transferring the order to the Gravesend Corporation is to be drafted, and in the event of its not being ratified, the Council propose to exercise the powers themselves, an extension of time for the purpose being applied for.

Edinburgh.—After considerable discussion the Corporation have adopted the following resolution: "That a sum of £14,175 out of the profits upon the electric lighting accounts for the year now closed, shall be placed to the credit of the electric lighting reserve fund; and that the balance of the said profits shall be placed to the credit of the rates, under the third head of estimate (general improvements), and that the acts of Council be modified and altered accordingly." The opinion was strongly expressed among a section of the Corporation that it would be premature to devote any of the profits to the relief of the rates until the depreciation fund had been made up to the full estimate.

London Gazette.—The partnership between William Frederick Ibbotson and Richard Green, carrying on business as electrical and mechanical engineers, and trading as Ibbotson and Green, has been dissolved by mutual consent. A general meeting of the Electric Magnetic Traction Company, Limited, will be held on Aug. 26 for the purpose of having an account laid before them showing the manner in which the winding up has been conducted and the property of the company disposed of; J. H. Howard has been appointed liquidator. A receiving order has been made out on debtor's petition in the estate of Harold Powell, electrical engineer, lately commission agent, 47, Northumberland-street, Derby, lately carrying on business at the Strand-arcade, Derby. The first meeting in the estate of Herbert Barham, engineer, 28, Bucklesbury, Hitchin, in the county of Hertford, and carrying on business at West-lane, Hitchin, will be held at 11 a.m. on Aug. 4 at the Court House, London.

Battersea.—At the last meeting of the Borough Council the Lighting Committee reported the receipt of a letter from the London County Council, with further reference to the adoption of a general and uniform method of fire-alarm indication throughout the Metropolis, and submitted a recommendation that the County Council be informed that the Borough Council approve of the design and the manner in which it is proposed to fix the indicators to the lamp posts, but are of opinion that the work should be undertaken by the County Council. Further recommendations submitted were that a meter testing room and meter stores be provided by the Works Department at an estimated cost of £153; that electric mains (including arc light leads) be extended from Northcote-road along Bramfield-road to Ashness-road, at an estimated cost of £142. 5s. 7d., applications for the supply of energy in that neighbourhood having been received; that the distributing mains and leads be extended to, and throughout, the Shaftesbury and Beaufoy Estates, and that 170 ½-ampere Nernst lamps be provided and fixed at an estimated cost of £3,653.

Watford.—The Watford and District Tramways Company having enquired whether the Council were prepared to supply energy for the purpose of the tramway, and, if so, at what date and upon what terms, the clerk was instructed to ascertain whether continuous or alternating current will be required, the maximum load demanded, and the date the supply is to commence. The Electricity Committee recommend that as soon as the answers to the queries which have been dispatched to various towns on the Continent where electricity is adopted for water pumping are received, the electrical engineer be authorised to accompany the surveyor to visit certain towns on the Continent, and to make a report on the subject. Sanction has been received to a loan of £26,000 for the extension of the generating station. The number of consumers connected to date is 345. The electrical engineer having reported that, as the majority of the consumers preferred to be charged on the flat rate instead of the demand indicator system, there were a large number of demand indicators in stock, and recommending that these be advertised for sale, the committee directed him, in the first instance, to send circular letters to the various electrical undertakings where demand indicators are used, inviting prices.

Cheltenham.—An analysis of the accounts of the electricity undertaking for the year ending March 31 shows that the capital was increased from £148,027. 11s. 11d. to £151,528. 5s. 7d., but the number of private consumers rose from 676 to 756, and the number of 8 c.p. lamps connected with the mains from 41,442 to 48,052. After payment of capital charges the undertaking shows a loss upon the year's working of £1,756, but this compares favourably with last year, when the loss amounted to £3,740. The number of units sold was 1,534,144 against 1,287,421 last year. For public lighting 607,314 units were used, private supply 474,795 units, and for traction 252,035 units. The average prices obtained were—private supply 5·03d., public lighting 2·17d., and traction 1·7d. The works cost of generation and distribution was 1·048d. per unit, and the total cost 1·459d. per unit against 1·57d. last year, a saving being effected in distribution. While the output of energy has only increased by 5·6 per cent., the revenue from electricity has simultaneously increased by 9 per cent. By the combination of reduced cost of production, increased output, and increased revenue on all energy supplied, except to the tramways company, the gross profit has been increased from £6,778 in 1902-3 to £8,469 in 1903-4. This gross profit is equal to a percentage of 5·65 of the expended capital.

Hammersmith.—The Electricity and Lighting Committee reported at Wednesday's meeting of the Borough Council that 14 additional consumers, representing a maximum of 418 8-c.p. lamps, have been

Digitized by Google

connected to the mains; that seven consumers have been disconnected, and that the present number of consumers taking current from the mains is 1 478. The borough surveyor reported that Messrs. Westwood and Wright had completed the laying of the pipes for the extension of the condensing scheme, at a total cost of £1,083. 7s. 8l. The committee recommended that a claim by the contractors for an extra allowance on account of the river being in flood during the progress of the work be not entertained. Tenders are to be invited for supplying pipes in connection with the river-water main extension. An application for supply has been received from No. 33, Digby-mansions, and the committee recommend that the necessary main be laid. A communication having been received from the London County Council with reference to the Bill to be promoted by them to authorise local authorities to execute wiring, the committee recommended that the Council give the measure their fullest support. It was further proposed that the whole of the vacant land at the rear of the electricity works, which belongs to the Council, should be allocated to the extension of the electricity undertaking. The Works Committee recommended the application of the Postmaster-General for permission to lay an underground telegraphic wire along the west side of Shepherd's Bush-road be granted.

Grimsby.—Mr. W. A. Vignoles, the borough electrical engineer, has circulated his third annual report for the year ending March 31 relating to the electric lighting undertaking. The report states that the most satisfactory feature of the year's working has been the increase in the number and horse-power of motors connected to the mains. The new system of charging (1d. per unit), with a time cut-off, has been introduced as an alternative to the ordinary system, and has been largely adopted. For the year ending March 31, 1903, the number of motors connected was 16, with a total of 45 h.p., the units sold for power purposes being 4,770. During the period under review the number of motors connected rose to 41, with a total of 167 h.p., the units sold for power purposes totalling 16,519. Steady progress was made during the year in securing new consumers for lighting. The number of private lamps connected numbered 31,812, against 22,559 in the previous year. The number of units used for private lighting was 255,835, against 185,622 in the previous year. For all purposes 799,602 units were consumed, against 653,438. The electricity department sold 442,628 units to the tramway company during this year, this being an increase of 70,000 units as compared with the previous year, and 90,000 units more than the guaranteed minimum. The total cost of generation and distribution was £4,125, representing 1·24d. per unit. A pamphlet issued by the electricity department give details of the Corporation's system of supplying energy, which can be had at 1d. per unit by consumers who do not require power after about five o'clock in the winter months. Any further particulars can be obtained from Mr. W. A. Vignoles, the borough electrical engineer.

London County Council.—The Finance Committee recommend the Council to grant loans of £10.000 and £9,958 for electric lighting works to the Woolwich and Shoreditch Borough Councils respectively; and that sanction be given to a loan of £433,800 to the St. Marylebone Borough Council for electric lighting purposes. The following notices under the Electric Lighting Acts have been agreed to: the Blackheath and Greenwich District Electric Light Company, high-tension mains along portions of Sydenham-road, West-hill, Charleville-circus, and to build a transformer box at the junction of West-hill and Crystal Palace-park-road, also low-tension mains along Burghill road and a portion of Pond-road; the Charing Cross and Strand Electricity Supply Corporation, mains across High-street, St. Giles, Holborn; the City of London Electric Lighting Company, to lay mains in Southwark; the County of London Electric Supply Company, to lay low-tension mains along Burstock-road and along Tranmere-street, also a transformer box at the junction of Franciscan-road and Lucian-road, Hazelwell-road and Upper Park Fields, and Deepdene-road and Gleneldon-road, also to lay high and low tension mains along Prentis-road, Becmead-road, Kings Court-road, Norfolk House-road, Moorcroft-road, Brancaster-road, and Blakemore-road, and to construct a transformer box at the junction of De Crespigny-park and Grove-lane; the London Electric Supply Corporation, to lay high and low tension mains along portions of Upper Ground-street, Old Barge House-street, Hatfield-street, and Broad-wall; the Metropolitan Electric Supply Company, to lay high-tension mains along portions of York-terrace, Devonshire-place North, Brunswick-place, and across York-gate; the St. James's and Pall Mall Electric Light Company, to lay mains along portions of Masons'-yard, Ormond-yard, York-street, St. James's-square, Charles-street, and Haymarket; the Westminster Electric Supply Corporation, to lay mains along portions of Eccleston-place, Eccleston-street, and Buckingham Palace-road; the St. Pancras Metropolitan Borough Council, to lay mains across Prince of Wales-road and along a portion of Castle-road and along a portion of Camden-road. The Fire Brigade Committee's report contained the following: "We are of opinion that the Eltham sub-station should be lighted by electricity. The Woolwich Metropolitan Borough Council is not yet in a position to supply electric current, but we understand that it will not be long before it is able to do so. Should the electric current not be obtainable when the station is opened in the autumn, temporary arrangements will have to be made for the lighting of the station. It is desirable, however, that the necessary wiring should be put in hand, and we have therefore given instructions for tenders to be invited from selected firms."

TRACTION.

Maidstone.—The first four days' receipts of the new cars amounted to £114.

Colchester.—The electric tramways satisfactorily passed the Board of Trade inspection on Wednesday, and the service was formally opened yesterday.

Derby.—The London-road to Alvaston and the Osmaston-road to Cotton-lane sections were opened to the public on Wednesday.

Lowestoft.—The trams completed their first year's running last Friday. The receipts up to the end of the week reached an aggregate of £10,457.

Droylsden and Audenshaw.—All opposition to the Manchester Corporation Bill, which authorises the promoters to electrically equip the Manchester, Audenshaw, and Droylsden tramways has been withdrawn.

Aberdare.—The Urban District Council have decided to promote a scheme for an electric tramway system from the centre of the town to Aberaman, with a branch to Cwmaman, and also for the erection of a refuse destructor.

Gravesend.—The Northfleet District Council have decided to make representations to the company with a view to obtaining a reduction of fares and the introduction of ½d. fares in Northfleet, the latter having been found to pay well in Gravesend.

South Australia.—The Government has forwarded to the secretary of the Adelaide and Suburban Tramway Company a legal notice stating that the Government propose to exercise its right of purchase, under the general Tramways Act, in October.

Tees-side.—Following on the agreement arrived at between the Imperial Tramways Company and the Middlesbrough Corporation before the House of Lords' Committee, the Thornaby Corporation have lodged a petition against any alteration of the Bill.

North Metropolitan Tramways Co.—The directors recommend a dividend at the rate of 3½ per cent. per annum for the past half year, carrying forward about £200. During the half year the number of miles run were 6,943,973, and passengers carried 64,301,765.

Parliamentary Bills.—On Wednesday the Tramways Orders Confirmation (No. 2) Bill was before a select committee of the House of Commons, Sir Lewis McIver presiding. Included in the Bill were the Sunderland Corporation Tramways Order, and the Bishop Auckland, Shildon, and Spennymoor Order. There was no opposition to the confirmation of these orders, and the Bill was ordered to be reported to the House.

Hanley.—The Town Council have received a letter from the Potteries Electric Traction Company stating that, after careful consideration, the directors regretted their inability to issue contract tickets, and also that they could not see their way to reducing the present fare between Hanley and the park gates, but adding that ½d. fares would be given a trial at an early date. As to the suggested extension of the light railway up High-street to the borough boundary at Birches Head, the chairman would go into the matter carefully when he was next in the Potteries district.

Metropolitan Electric Tramways Co.—A Press inspection of the company's extensive main power station at Brimsdown took place last Friday, the party subsequently visiting the depôt at Edmonton and the sub-station at Wood Green, returning on reserved cars to Finsbury Park, the terminus of the section opened to the public on that day. Several other sections are well advanced, and when these are completed communication will be provided from North London to several districts in Hertfordshire, arrangements for inter-running having been entered into with other existing or projected systems.

Newcastle.—The company's Bill was finally amended at the sitting of the House of Commons Committee last Friday. Clauses 15 and 16 being struck out, a clause was inserted confirming and giving effect to an agreement between the company and the Corporation for the running of cars by the company over the Corporation lines and by the Corporation cars over the company's system; and fixing a scale of charges and other arrangements for through traffic. The agreement itself was inserted in the Bill as a second schedule. A clause was also agreed to providing that in the event of the sale of their undertaking by the company the arbitrator in determining fair market value shall not have regard to any increase of value directly due in his opinion to the exercise by the company of powers conferred by the agreement. The Bill thus amended was reported to the House.

Torquay.—The Tramways Bill was read a third time in the House of Lords on Monday. On the motion that the Bill be passed, Lord Clifford of Chudleigh moved to insert the following new clause: "If at any time it be proved that any injury or damage to any mains, pipes, or apparatus of the Corporation, or the Torquay Gas Company, shall have resulted from the use of electric current on any of the tramways authorised by this Bill, nothing in the Bill shall relieve the company from liability to make compensation for such injury or damage." This clause had been allowed by the committee, but had been subsequently struck out at the instance of Lord Balfour of Burleigh as being contrary to precedent. The committee did not desire to establish a precedent, but considered that the circumstances of the case justified the clause. Lord Wolverton, as representing the Board of Trade, now opposed the motion. Eventually the proposed clause was negatived without a division, and the Bill was then passed.

Ossett.—On Wednesday the Select Committee of the House of Commons presided over by Sir Lewis M'Iver considered a Bill to confirm, *inter alia*, a tramway order granted by the Board of Trade to the Corporation of Ossett. The Great Northern Railway Company opposed. It was announced in the course of the proceedings that a settlement had been arrived at, and under the circumstances the Bill will in due course be considered by the Committee on Unopposed Bills. It is stated that the effect of the arrangement come to by the parties is that the Corporation of Ossett and the Corporation of Dewsbury can carry goods on their tramways within their own boroughs, and in the case of Ossett also into the urban district of Horbury, and in the case of Dewsbury anywhere within a radius of two miles from Dewsbury Town Hall, but subject to these provisions there is to be no carriage of goods on the tramways of either Corporation in competition with the Great Northern Railway Company.

Digitized by Google

Wellington (N.Z.).—It is anticipated that the electric trams will start running in a few weeks. The fares have been fixed at 1d. per 96 chains.

Birmingham.—Representations are to be made to the Corporation upon the necessity of providing a tram service to Harborne at as early a date as possible, as many workers are engaged in that district.

Metropolitan District Railway Co.—The directors announce that the accounts will, after paying all prior charges, admit of a payment for the six months ended June 30 of a divinend on the 4 per cent. guaranteed stock at the rate of 2 per cent. per annum.

Brighton.—The Town Council have decided to discontinue the service on the cross route from Seven Dials to Elm-grove. The report of the special committee on the question of revising the fares has been adopted, penny stages to be limited, as far as possible, to 1½ miles.

Proposed Light Railway.—The Ripon Rural District Council last week received a deputation of ratepayers who were in favour of a light railway to Kirkby Malzeard. A fund has been raised towards a preliminary survey, and the District Council will recommend an engineer for the purpose.

North-Eastern Railway.—It is stated that the company contemplate letting a contract for the electrification of the Newcastle and South Shields branch. Experiments have been conducted on this section for some time past. On the south side of the river the railway passes through a very crowded district.

Dewsbury and Ossett.—Petitions have been lodged in the Private Bill Office of the House of Commons on behalf of the Great Northern Railway Company praying to be heard, by counsel, against the Dewsbury Corporation Tramways Order and the Ossett Corporation Tramways Order, when they reach the committee stage.

Liverpool Overhead Railway Co.—The accounts of this company for the past half-year show an available balance of £10,370. 18s. 6d., and the directors have resolved to recommend payment of a dividend at the rate of 5 per cent. per annum on the preference shares, and 1½ per cent. per annum on the ordinary shares. Balance carried forward £4,052. 5s. 10d., against £3,747. 5s. 10d. last year.

Tipton.—At Tuesday's meeting of the District Council allusion was made to the recent meeting at Birmingham between the local authorities and the company. The terms required by the Dudley Council for a lease to the company of the lines within their area, which terms the company consider decidedly excessive, appear to be the obstacle in the way of Tipton's requirements. A special meeting of the Council is to be held to-day.

Reading.—The parts of the track in the busy quarters of the town were laid with basic lava, bonded on a mixture of pitch and oil, to prevent noise. The new method proved a success in this respect, but, as anticipated by the borough engineer, it lacked durability. Last week one of the streets originally constructed on this principle—Duke-street—was relaid, the material used consisting of creosoted wood blocks, with edgings of jarrah wood.

Whickham.—The committees of the Whickham and Blaydon Councils met the representatives of the Gateshead and District Tramways Company, when the question of having the trams extended from Dunston to Blaydon was fully discussed. Ultimately the company's representative intimated that until the Local Government Board had passed its Bill to amend the Light Railways Act he was afraid his company could not deal with the matter.

Cardiff.—Owing to inconsistencies in the fare stages, Mr. Arthur Ellis, the engineer and manager, recommends the Corporation to raise the fares all round by charging ½d. stages, with a minimum of two stages for 1d. He works it out on the basis of 1,100 yards for ½d. and 2,200 yards for 1d. The minimum of 1d. is introduced because ½d. fares for one stage would fill the trams for short distances to the exclusion of the more profitable through passenger.

Leith.—In view of the advanced stage now reached by the tramways provisional order, under which the Town Council propose to acquire and reconstruct the present horse tramway system, the Tramways Committee have appointed a sub-committee to make enquiries regarding all systems of traction. It is expected that the sub committee will report to the Tramways Committee early in September. A visit has been paid to Perth to inspect the new petrol tramway car of the Corporation.

Victoria.—At a recent meeting of the Executive Council, states the *N.S.W. Railway Budget*, the necessary Order in Council giving permission to instal an electric system of tramways for Essendon and Flemington was issued. Apparently the undertaking is to be conducted by private enterprise, as a *plébiscite* of the ratepayers is to be taken, the Electric Light and Power Act, 1901, providing that no municipality shall transfer any such powers until a poll shall have been taken in order to ascertain whether or not the ratepayers desire to forbid the proposed transfer.

Taunton.—The borough surveyor having reported that the foundation of the tramway company's track was in a bad condition, the company, though not prepared to lay wood blocks, offered (*a*) to lay, as an experiment, 50 yards with granite setts in the centre and margins of the track; or (*b*) they would consider the question of laying wood blocks if the Council would pay the difference between the cost of wood blocks and granite setts, and give the directors a price for the annual upkeep of the track. Eventually the Council decided to ask the company to try granite blocks in Station-road.

Road Widening.—The Metropolitan Borough Councils' Association have passed the following resolution, which has been forwarded to the various councils: "That when a widening becomes necessary solely by reason of the construction or reconstruction of the tramways, the expense should be entirely borne by the London County Council out of the tramway account. When an improvement is urgently required, irrespective of tramways, the contribution of the local authority should vary according to the importance of the improvement to the borough, apart from the tramway traffic." The circular has been accorded a somewhat mixed reception.

Huddersfield.—The Town Council have approved an agreement with the London and North-Western and the Lancashire and Yorkshire Railway Companies with reference to the laying of a tramway in the goods yard at Hillhouse. The accounts for the three months ending June 30 showed the receipts to be £17,417. 3s. 8d., giving a surplus (without allowing anything for depreciation) of £2,406. 10s. 2d. The receipts were equal to 9·93d. per car mile, as compared with 9·81d. last year. For the month of June the traffic receipts totalled £5,509, with average receipts of 9¼d. per mile, showing a slight decrease over the corresponding period of last year, when, however, the Whitsun holidays were included.

Garstang and Blackpool Light Railway Co.—The Light Railway Commissioners held an enquiry at Preston on Monday into the application of the company for an extension of the order authorising the construction of a light railway from Blackpool to Catterall. It was stated on behalf of the promoters that sufficient capital would now be forthcoming, and it was asked that the name should be changed to the Blackpool and Fylde Light Railway, to distinguish it from the Garstang and Knot End Railway. The order was extended for 18 months. An application by the Blackpool Corporation that the company should cross underneath a new road, on the ground that a level crossing would be dangerous, was dismissed.

New York Underground Railway.—The new underground rapid transit tunnel in New York, connecting the lower part of Manhattan Island with the northern districts of New York City, has been completed, and it is expected that trains will begin running by Sept. 1. The railway is a four-track one, and extends a distance of about 12 miles. Express trains will be run at the rate of 30 miles an hour. Work was begun on the tunnel on March 24, 1900, the price paid by the city for the tunnel being £7,000,000. A special feature of the subway is that each station will be distinguished from the others by a separate combination of colours, thus permitting those who habitually use the system to recognise their station immediately. It is estimated that in the rush-hours of the mornings and evenings the railway will be able to transport 40,000 persons an hour.

Hertfordshire Light Railways.—The Herts County Council have empowered the Highways Committee to open negotiations with the Urban District Council of Watford, assuming the Watford Tramways Company allow their powers to lapse on Aug. 17, 1904, as to the extension of the Bushey Light Railway into the town of Watford. The committee were directed to enter into negotiations with the Urban District Council of Cheshunt for an agreement enabling the County Council to construct the permanent way of the Cheshunt Light Railway with reasonable widenings. The seal was affixed to an agreement with the Metropolitan Electric Tramways, Limited, on the lines of the Cheshunt agreement, for the construction of the Barnet Light Railway, and the committee were empowered to take the necessary steps to acquire the lands required for widening the main road at Barnet, along which the above light railway will pass.

Ilford.—The tramway returns for the period March 14, 1903 to March 31, 1904, the first year of working, give the following particulars: population, 52,000; system and gauge, overhead trolley, 4ft 8½in.; length of single track, 10½ miles; total capital expended, £132,874. 3s. 11d; revenue, traffic revenue £22,587. 17s. 1d., other sources £630. 0s. 8d.; costs, operating £13,566. 1s. 3d., per cent. to revenue 60; interest on loan capital, £3,345. 4s. 4d.; gross profit before providing for interest, depreciation, or sinking fund, £9,649. 16s. 6d.; amount provided for depreciation or sinking fund, £2,291. 0s. 6d.; surplus, £4,570. 17s. 9d. (£557 being refunded by the lighting department for interest and sinking fund on machinery paid for out of the tramways loan); car miles run 577,034, passengers carried 5,274,025, passengers per car mile 9·14, times population carried 101, revenue per car mile 9·38d., revenue per passenger 1·02d., cost per passenger ·61d., units per car mile ·99; units consumed 585,041 (less 10,800 used on water-cart), power costs 1·54d., traffic costs 3·33d., maintenance and renewals ·48d., management expenses ·29d., total operating costs 5·64d.

Halifax.—Some weeks ago a meeting of the representatives of the District Councils of Soyland, Sowerby, Rishworth, and Barkisland was held with the object of inducing the Corporation to extend their tram service. At subsequent meetings a scheme was prepared, and arrangements made for an interview with the Tramways Committee. This took place on Thursday of last week. The needs of the districts and the advisability of providing better access to the locality were laid before the committee. Emphasis was laid on the fact that the Corporation had had the powers for nearly five years, and if not taken advantage of these powers would lapse, and thus would open the possibility of another authority obtaining them. The distance over which they were anxious lines should be laid was about three miles, and extended from a present terminus at Jerry-lane, Sowerby Bridge, to Slitheroe Bridge, Rishworth. Along the line of route there was a population to be served amounting to about 8,000. The deputation considered there was every possibility of it being a paying venture. The omnibuses had paid when run to Halifax, and the district was also an exceedingly picturesque one, and would prove an excellent holiday route. It is understood that the Tramways Committee, prior to giving a definite reply to the deputation, will inspect the proposed route at an early date.

London County Council.—The Highways Committee submitted a proposal that £4,960 be voted for top-covered cars. The Parliamentary Committee submitted a recommendation that £6,500 be paid to the London, Camberwell, and Dulwich Tramway Company for their undertaking, as arranged before the House of Lords' Committee. It was further proposed that £1,000 be expended on the repair of this track. In reply to the invitation from the New York Rapid-Transit Railroad for a representative to attend the opening ceremony in September, it is proposed that Mr. J. Allen Baker, the chairman of

Digitized by Google

the Highways Committee, represent the Council. Approval was recommended to the plan submitted by the City and South London Railway Company for a station to be erected at Euston. Sanction was asked to the expenditure of £58,800 for paving works and the construction of a further portion of the tramway in connection with the system under Kingsway and Aldwych. The receipts for the week ending 16th inst. totalled £14,710 against £10,675 last year; and for the period from April 1 they amounted to £185,758 against £152,641.

Burnley.—The Corporation tramway accounts to March 31 show for the Darwen section a gross profit of £2,825. 5s. 3d., but after making provision for interest on loans, repayment of principal, and sinking fund, amounting to £3,638. 17s. 11d., a net loss is shown of £813. 12s. 8d., as compared with a net loss for the previous year of £1,109. 5s. 2d. This is allowing £900 for depreciation, apart from which there would have been a small profit. The traffic receipts for the year on this section have been £10,664, as compared with £10,743 last year, showing a reduction of £79, attributable to the depression in the cotton and other trades. The revenue account for the Hoddlesden section shows, after debiting £150 for depreciation, a gross profit of £82. 7s. 1d., but after making provision for interest on loans and sinking fund instalments, a net loss of £672. This loss is reduced by the sum of £350 due from guarantors, leaving the net loss at £322, as compared with a net loss for the previous year of £441. The total amount now standing to the debit of tramways net revenue account is £2,949. The total number of miles run and the average traffic receipts per car mile are as follows: Darwen section, 221,613 miles; traffic receipts, 11·5884d.; Hoddlesden section, 31,732 miles; traffic receipts, 12·6892d., as compared with year ended March 31, 1903—Darwen section, 222,329 miles; traffic receipts, 11·5973d.; Hoddlesden section, 31,951 miles; traffic receipts, 11·6174d.

Rochdale.—The Board of Trade inspection of the Mellor-street route took place last week, preparatory to its being used for traffic from Norden to the town hall. Major Druitt (the inspector) and a party of councillors and officials, including Mr. C. O. Atchison (borough electrical engineer) and Mr. J. S. D. Moffett (tramways manager) made the journey in a single-decker combination car, which ran through from the Esplanade to Spotland Bridge in quick time and without the slightest mishap, the car running very smoothly. On the return journey a halt was made at the car-shed at Bridgefold to enable Major Druitt to have a look over the premises, with the appearance and arrangement of which he expressed warm satisfaction. The car containing the party returned to the Esplanade at 10.15, exactly 19 minutes after leaving for the outward journey. Major Druitt was well satisfied with the short trip, and gave the Corporation power to run at 12 miles an hour over the new section, and to use it for traffic immediately. A fortnight ago he sanctioned running at the rate of 12 miles an hour along the Esplanade, these being the only lengths on the Corporation lines where that pace is allowed. On the other sections the pace varies from eight to ten miles an hour. The relaying of the lines at the bottom of Drake-street is now practically finished. So far as track is concerned the circular route is now completed. The road on the Butts side of the river covering has to be raised and men were started on that work on Thursday morning of last week. On the Manchester-road single lines have been laid as far as Brimrod-lane, and double track has been put down to a point opposite Cheltenham-street. When the work around the river covering is absolutely completed, men will be concentrated on the reconstruction of the Manchester-road section as far as the Windmill Inn at Sudden.

Spen Valley.—The Yorkshire (Woollen District) Tramways, Limited, on Saturday issued the following notice: "Owing to the impossibility of coming to a satisfactory agreement with the Heckmondwike Urban District Council for the supply of power, the company find it impossible to maintain the present service running through the Heckmondwike district." Before the company commenced operations an agreement had been entered into with the Heckmondwike Council, under which the latter were to supply for use within the township a minimum quantity of current to the company per year at a stipulated price per unit, providing that more current was not required at once than could be produced by a plant of a certain kilowatt capacity. Almost as soon as the cars commenced running it was found that the demand greatly exceeded the capacity of the plant. Under the agreement the Council were to be paid an additional £12. 10s. per annum for each extra kilowatt required to meet the maximum demand of the company. Finding that the latter were unwilling to comply with this arrangement, the Council restricted the supply to very little beyond the quantity they were called upon to provide at any one time. The result was a frequent stoppage of cars and a dislocation of the service. Ultimately the Council agreed that they would accept a smaller sum than £12. 10s. per kilowatt, and a full service was resumed on the understanding that whatever extra payment was agreed upon subsequently had to be retrospective. The company, whose contention is that they are called upon to pay an unreasonably high price per unit, and that the larger plant can be utilised by the Council for other purposes, appealed to the Board of Trade, but the reply was that they could not interfere with the agreement the parties had already come to. The Council express a desire to deal with the company in a conciliatory spirit, and have recently had a further conference with their representatives, but it is stated that the amount offered by the directors in lieu of the £12. 10s. per annum per kilowatt is utterly inadequate.

Bury.—On Tuesday of last week a trial trip was taken on the Manchester-road section, and was highly successful. The car was driven by Mr. Clough, the tramways manager, and the party included the Mayor, members of the Tramways Committee, and other councillors, and Mr. S. J. Watson, the borough electrical engineer. The whole of the section to the borough boundary was traversed, and the journey outward and inward was performed without a hitch, a special feature being the smoothness with which the car ran and took the points. On the following morning Major Druitt, of the Board of Trade, inspected the section. A car, containing the inspector, members of the Corporation, and officials, again proceeded over the whole of the route, the result being very satisfactory. Immediately after the inspection was concluded, a 10 minutes' service was commenced from Limefield to the Unsworth boundary at Whitefield. The fares on the Manchester-road section have been fixed as follows: from the parish church to the Cemetery Hotel, 1d.; Cemetery Hotel to the Unsworth boundary, 1d.; parish church to Blackford Bridge, 1½d.; parish church to Unsworth boundary, 2d. Major Druitt fixed the speeds as follows: Market-place and Market-street, eight miles; Knowsley-street, 12 miles; and Manchester-road, 14 miles an hour; four miles an hour round curves. An effort is being made to get the Bolton-road sections of the trams opened by Bank Holiday. Following on the reception of the referee's award in the arbitration proceedings between the local authorities and the tramway company, a conference of the authorities interested was held. At the same time that Mr. More, the valuer for the authorities, submitted his valuation of the undertaking, he also sent a sealed packet containing an apportionment of the amount which each authority would have to pay if his valuation were accepted by the arbitrator. The apportionments were made on the principle of the car mileage run in each district, and are without regard to the sum which may be obtained for the rails, cars, engines, depôts, etc. When these are sold off, the amount will be deducted *pro rata* to the amount paid by each authority. As Mr. More's valuation was not accepted, the packet was not opened, and it was decided to return it to him in order that he may alter it in accordance with the amount of the award.

PROVISIONAL PATENTS, 1904.

JULY 18.

15932. Improvements in incandescent electric lamps. Max Sommer, 56, Ludgate-hill, London.

15942. Improvements in alternating-current electric meters. Union Elektricitäts-Gesellschaft, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, July 18, 1903, being date of application in Germany.) (Complete specification.)

15952. An electrode for electrical accumulators. Karl Ludwig Berg, 18, Buckingham-street, Strand, London. (Date applied for under Patents Act, 1901, July 18, 1903, being date of application in Sweden.) (Complete specification.)

JULY 19.

15981. Improvements in telephone directories. Myron George Brownell, 52, Chancery-lane, London. (Complete specification.)

16026. Improvements in vapour electric apparatus. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

JULY 20.

16038. Improved telephone system. Bertil Brander, 5, Prinz Heinrich-strasse, Karlshorst bei Berlin, Germany.

16059. Improvements in apparatus for the generation of electricity, primarily designed for the electric lighting of trains. Thomas William Stainer Hutchins, 17, St. Ann's-square, Manchester.

16063. Improvements in connection with electric safety fuses. Joseph John Smith, 6, Finkle-street, Stockton-on-Tees.

16088. Improvements in alternating-current electric motors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

16109. Improvements in reverse electric current switches or circuit breakers. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

16110. Improvements in and relating to electromagnetic mechanism. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

16113. An improved method of treating incandescent lamp filaments to increase their density and also the density of the carbon deposited upon them during the flashing process. Louisa Calvert and William Arthur Snape, 173, Fleet-street, London.

JULY 21.

16155. An improved method of economising space over the third or "live rail" on electric railways. Henry Curwen, 32, Sidney-grove, Newcastle-on-Tyne.

16166. Improvements in surface-contact systems for electric tramways and the like. Thomas Meredith Trumble and Joseph Patrick Trumble, 5, Budge-row, Cannon-street, London.

16171. A shield or guard for the prevention of injury to workmen and others by accidental contact with exposed "live" rails or current distributors on electric railroads and the like. John Thomas McCoy, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

16179. Improvements in electrical transformers. John Sedgwick Peck and Charles Le Geyt Fortescue, The Westinghouse Patent Bureau, Westinghouse-buildings, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Aug. 8, 1903, being date of application in United States.) (Complete specification.)

Digitized by Google

16161. An improved electric candle nozzle. Frederick Thomas, 189, Drummond-street, Hampstead-road, London.

16205. Improvements relating to electric furnaces and to the extraction of zinc by means of the same. Arthur Edelmann and Nils Wallin, 37, Essex-street, Strand, London. (Date applied for under Patents Act, 1901, July 23, 1903, being date of application in Germany.) (Complete specification.)

16210. Improvements in electrical winding and switching mechanism. Edward Du Bois, Norfolk House, Norfolk-street, Strand, London. (Complete specification.)

JULY 22.

16241. Improvements in or connected with electric arc lamps. James Brockie, 33, Chancery-lane, London.

16242. Improvements in electric lights. Heinrich Beck, 216, Friedrichstrasse, Berlin, S.W., Germany.) (Date applied for under Patents Act, 1901, July 24, 1903, being date of application in Germany.) (Complete specification.)

16256. Improvements in systems of electrical distribution. Ezechiel Weintraub, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, July 23, 1903, being date of application in United States.) (Complete specification.)

16257. Improvements in systems of electrical distribution. Ezechiel Weintraub, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, July 23, 1903, being date of application in United States.) (Complete specification.)

16258. Improvements in transforming the energy of electric currents. Ezechiel Weintraub, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, July 23, 1903, being date of application in United States.) (Complete specification.)

16260. Improvements in electrical controllers. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

16261. Improvements in apparatus for electrically heating liquids. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

16267. Deposition of zinc or other metals by means of electricity. Frederick William Gauntlett, Tower Royal, Cannon-street, London.

JULY 23.

16311. Improvements in electrical signalling apparatus for railways. William Andrews, Frederick Allcock, and William Keyworth, 111, Hatton-garden, London.

16312. Improvements in or relating to the detection of electrical oscillations. Louis Heathcote Walter and James Alfred Ewing, 111, Hatton-garden, London.

16324. Improvements in galvanic elements or batteries. Simon Gerardus Visker and Philip Cohen Kaz, 77, Chancery-lane, London.

16326. Improved apparatus for use in the teaching of electric, telegraphic, and other signalling by means of the Morse or other similar codes. William McDonald, 53, Chancery-lane, London.

16340. Improvements in and relating to electric couplings. William Chater Lea, 323, High Holborn, London.

16340. Improvements in or relating to selective electric switches. Isidore Bernard Birnbaum and Francis George Bell, 322, High Holborn, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Aug. 11, 1904.

1903.

15979. Electric tramcars. Lycett and Conaty.

16368. Portable electric accumulators. Ramsbottom and Richardson.

17179. Electric railway systems and apparatus for use therein. Lake. (Morgan Electric Machine Company.)

17207. Dynamo-electric machines. Dutton and Sandycroft Foundry Company, Limited.

17063. Reversing mechanism for dynamos. Manley.

18121. Enclosed or open electric arc lamps. Mensing.

19048. Alternating-current induction motors. Hunt and Sandycroft Foundry Company, Limited.

21742. Ships' telegraphs. Watters.

1904.

4063. Means for rupturing electric circuits. Thomas. (Date applied for under International Convention, June 27, 1903.)

4063A. Means for rupturing electric circuits. Thomas. (Date applied for under International Convention, June 27, 1903.) (Date applied for under Patents Rule 9, Feb. 25, 1904.)

5185. Method of receiving electrical vibrations utilising electrolytic cells. Thompson. (Gesellschaft für drahtlose Telegraphie m.-b.-H.)

7586. Electric telegraphy. Kitsee.

8444. Safety devices for electric railways. Gibbs.

12439. Electric fire-alarm and the like signalling apparatus. Hubber and Higgs.

12449. Small meter for alternating electric current. Reiss and Klemm.

13724. Electric drills. Duntley.

13758. Portable electric lamps. Hubbell. (Date applied for under International Convention, July 2, 1903.)

13968. Means for producing electric arcs from alternating currents, also applicable for rectifying alternating currents. Weintraub. (Date applied for under International Convention, June 20, 1903.)

13933. Electric storage battery separators. Boult. (Dodge.)

NOTES.

Armour Institute.—We have received the 1904-5 year-book of the above institute at Chicago. The syllabus of the instruction given in the different subjects shows that the institute is well up to date. Electrical engineering is well represented, there being separate courses for electric light and power engineers and for telephone engineers.

Wellington Tramways.—The trial run of electric tramcars in Wellington, N.Z., took place on June 8, and was extremely satisfactory. In consequence, the first routes, we note, have now been opened to the public, and we understand that the contractors, Messrs. Macartney, McElroy, and Co., are completing their work promptly. There is, unfortunately, a certain amount of delay in the construction of one or two tramlines, for which we understand these contractors are by no means responsible.

Underground Telephone Wires in Bombay.—Fortunately for the inhabitants of Bombay, the local telephone company required a new contract with the municipality just before the introduction of electric traction. In consequence, there were clauses inserted in the new contract under which the telephone company have to lay their wires underground wherever necessary. In consequence of this the telephone company have already put a large number of their wires underground, and have pulled down the old overhead construction. As a result, there is not likely to be that interference between telephones and tramways, with the consequent danger to the public, which has been experienced in other towns in different parts of the world.

Standard Sections.—The Engineering Standards Committee have just issued a book entitled "Properties of British Standard Sections." These cover all the steel and iron sections adopted by the then sub-committees dealing respectively with shipbuilding, bridges, and general building construction and railway rolling-stock underframes. The preparation of this work has entailed a vast amount of labour, and no pains and expense have been spared to ensure the accuracy of the results contained therein. "The Properties of British Standard Beams," which was issued in advance, by special request, in the autumn of last year, is contained in the present volume. The general preface gives an idea as to the method adopted in arriving at the list of standard sections. The mathematical preface contains useful information on moments of inertia, ellipse of inertia, moments of resistance, etc. The list of members of the three committees responsible for the compilation of the lists of standard sections is included also in the volume, which must find a place in every engineer's office.

In a Magnetic Cloud.—The following has received the credit of a good evening paper in this country, and it speaks volumes for the knowledge of the sub-editor of the same. Obviously the story has crossed the Atlantic, and we presume that the writer was either approaching or receding from a "bar" at the time he was delivered of the paragraph. We admire the vivid description of the magnetic, electric, and gravity storm cloud quite as much as we do the transparent veracity of the writer. The British ship "Mohican," which has arrived at Philadelphia, reports having passed through a magnetic cloud while approaching the Delaware breakwater. Fire played across the metal ship from stem to stern, the needle of the ship's compass flew around like an electric fan, and everything was magnetised. It was impossible to lift even light chains or bars, which clung tightly to the iron deck. The captain says: "The hair of our heads stuck out like bristles, and it was difficult to move the arms or legs. Suddenly the magnetic cloud lifted, and the phosphorescent glow around the ironwork vanished, and things became as usual."

St. Louis Railway Congress.—In addition to the five papers which are to be presented at the convention of the American Railway, Mechanical, and Electrical Association on Oct. 10 and 11, there will be a question box. It is hoped that this will give rise to very interesting discussions on subjects apart from the topics on which the papers are being prepared. The papers to be read and discussed are as follows: "Inspection and Maintenance of Electrical Equipment," by Messrs. Baker and Lindall, of the Boston Elevated Railway, Boston, Mass.; "Wheels," by J. Millar, of the International Railway Company, Buffalo, N.Y.; "Universal Street Car Body," by W. W. Annable, Grand Rapids Railway Company, Grand Rapids, Mich.; "The Ideal Shop," by W. D. Wright, of the Rhodes Island Company, Providence, R.I. There will also be a joint meeting with the accountants on Oct. 14 to discuss "Shop Records and Accounts." H. H. Adams, of Baltimore, and G. and E. Farrington, of Boston, have this matter in charge for the mechanics, and G. M. Pease, of Buffalo, and W. T. McDole, of Cleveland, are to represent the accountants. The headquarters of the American Railway, Mechanical, and Electrical Association will be at the Inside Inn during the convention period.

Junior Institution of Engineers.—The summer meeting of the institution this year is to be held in Germany, Düsseldorf being the first stopping place. Here, at the town hall on Saturday, Aug. 13, the members are to be welcomed into the Fatherland by the burgomaster and the Society of Architects and Engineers of Düsseldorf. The exhibition will be visited, and on Monday there will be an excursion to Oberhausen for viewing the works of the Gutehoffnungshutte (blast furnaces, steelworks, etc.). The Beurather Crane Works will also be seen. On Tuesday the Elberfeld-Barmen monorail suspended railway is to be inspected in the morning, and in the afternoon the members proceed to Hanover for the purpose of visiting on the following day Messrs. Korting Bros.' works, the Hanover Engine Works, and the works of the Westinghouse Brake Company. Thursday morning will be spent at Hanover, and in the afternoon Berlin will be reached. Here, on Friday, the Overhead and Underground Railway will be seen, including car-sheds, generating station, etc.; also the Charlottenburg electrical engineering works of Messrs. Siemens and Halske. Saturday, Aug. 20, will be spent in visiting the Mariendorf works of the Imperial Continental Gas Association and the Royal Technical High School at Charlottenburg. The members leave Berlin on the Monday for Leipsic, remaining there till Wednesday, when they go on to Frankfurt-on-Main to visit on Thursday and Friday, by invitation of Mr. W. H. Lindley, M.I.C.E., the municipal works, with an excursion to Homburg. On Saturday, Aug. 27, the return journey to England will be made to include the Rhine from Brebrich to Bonn.

Standardisation of Fuses in America.—In order to overcome the difficulties due to the lack of uniformity of sizes and ratings of the various enclosed fuses now upon the market, and to be able to suggest to manufacturers proper details of construction for obtaining the most satisfactory dimensions in securing interchangeability of the fuses for any given capacity, a committee of the Underwriters' National Electric Association, of the United States, has been collecting information regarding the enclosed type of fuse from manufacturers all over the country, and has been conducting a series of tests to determine experimentally the advantages of certain constructive features. Through co-operation with the Edison Illuminating Company, of Boston, and the Boston Elevated Railway Com-

Digitized by Google

pany, tests were conducted in the large power stations of these companies to ascertain the operation on short-circuit and otherwise of fuses of very large capacities, at 220 and 550 volts. The tests were so arranged that the fuses were subjected to conditions equivalent in all respects to those which obtain in any large system. As a result of the information obtained from the manufacturers and from the tests, the committee has recommended certain standards which are about to be adopted by the National Board of Fire Underwriters. According to the recommendations, the ferrule type contact clip is to be used for all sizes not exceeding 60 amperes and for all voltages up to 600, while for currents from 61 to 600 amperes the knife-blade contact type is required. The length of a 200-ampere 250-volt fuse is to be 4·5in. between clips, while a 200-ampere 600-volt fuse is to be 7in. The results of such free and friendly co-operation between the underwriters, the manufacturers, and the users of electrical devices should, says our contemporary the *Electrical World*, be greatly beneficial to all electrical interests, and the securing of a standard in fuse dimensions at this time will be a distinct step in advance.

Reliability Trials for Motor Boats.—The following is an abstract of a report to be presented to the committee of the Automobile Club of Great Britain and Ireland on Aug. 8 respecting the recent trials of motor boats. The judges (Major Lindsay Lloyd, Lieutenant Mansfield Cumming, and Captain R. E. T. Dixon) with commendable promptitude have prepared their report, in which, after dealing with the number of competitors and general arrangements of the trials, they express their satisfaction at the results of the trials and at the proved reliability of the boats taking part, only two of the 16 starters failing to complete the 20 hours' run, five boats making complete non-stop runs. The report proceeds with an appreciation of the good performance of the Seal and the Vosper boats using ordinary paraffin, and of the good general condition of all the boats at the termination of the 20 hours. One of the most important recommendations of the report is dealt with at some length—viz, that of the safety of boats fitted with internal-combustion engines—and the effects of this recommendation should be evident in next year's trials. The question of convenience of general arrangement of details is also treated of, the Napier Minor and the Maudslay boat being taken as examples of excellence in this direction. After expressing approval of the general lines of the present trials, suggestions are made as to further points for marking in future trials, with a recommendation that further trials should be held. The report concludes by recommending the following awards: Class II.—Seal Motor Company, 2½-h.p. 18ft. launch, gold medal. Class III.—Vosper and Co., 12-h.p. 22ft. launch, gold medal; Mitcham Motor Company, 6-h.p. 22ft. launch, silver medal. Class IV.—Maudslay Motor Company, 20-h.p. 25ft. launch, gold medal; Woodnutt and Co., 10-h.p. 30ft. launch, silver medal. Class V.—S. F. Edge, Esq., 5-h.p. 35ft. launch, gold medal. Class VI.—J. I. Thornycroft and Co., 20-h.p. 30ft. launch, silver medal. The judges expressed their satisfaction with the admirable fashion in which Mr. Basil Joy, the secretary, had organised the trials.

German Tramway Practice.—The *Street Railway Journal* of New York publishes an interesting article on German axle, wheel, and rail practice which is contributed by a German engineer. In it reference is made to the recent meeting of the Rheinisch-Westfälische Strassenbach-Betriebsleiter-Vereinigung held in Essen, when the members witnessed at the Krupp Works a series of remarkable tests of Martin crucible steel and nickel-steel street railway car axles. An equal number of finished axles, made of the two materials named, all 110mm. (4·33in.) in diameter, were subjected to several cold bending tests under a pressure of 5,000 tons. In the first trial one axle of each material was bent round a core of 120mm. (4 72in.) radius. The nickel-steel axle assumed the shape of the letter U, but failed to show the slightest evidence of rupture, whereas the Martin steel axle showed a break about 1in. deep on its outer surface. Another set of axles was taken for the second trial, but before bending each axle was notched in the centre with a heavy chisel. The nickel-steel axle again took the shape of a U without any apparent increase in the depth of a notch, but the other axle broke in two before one-fourth of the bending process had been completed, despite the fact that it was made of the best Martin steel. It is well known that most axle breakages occur at a sharp edge, as at the corner of the gear seat, and accidents of this kind, it is thought, will be avoided by the use of nickel-steel axles. Although these axles cost 40 per cent. more than those of the ordinary steel, they are largely used in Germany. The author goes on to describe the improvements in wheel-tyre material due to the introduction of nickel steel. Harder rails are being sought for in Germany, with the result that there is a considerable increase in the use of open-hearth steel for such work. As the result of this demand for harder rails, recent railway specifications call for a considerably lower drop test, for the reason that it is very difficult to get the required hardness of the rails if the former tensile strength is maintained, and because in tramway service tensile strength is really of less importance than hardness. For testing the homogeneous condition of the rails the etching test has recently been largely used. As a substitute for breaking tests, certain companies are now beginning to prescribe rolling pressure tests.

Calibrating Integrating Meters.—Mr. Douglas P. Morrison contributes to the columns of the *Electrical World* the following details of a simple method of meter testing he has developed to save labour. The method is applicable to any type of meter, of any size or capacity, but in the writer's present experience has been used only with two wire meters of the induction type. In its use neither the windings nor other electrical features of commercial meters need be altered, the only change made being in the recording mechanism, the gears being adjusted to a ratio of 10 to 1 between the disc shaft and the first indicating hand. There are provided two hands which record and repeat 100 revolutions of the disc. The disc being graduated to 100 parts, from the combination of disc and dial, revolution and fractions thereof from $\frac{1}{100}$ to 100 can be observed. In the shunt circuit of the "standard meter' is introduced an ordinary ball spring switch. The method of use is as follows: The "standard" and the "unknown" are so placed in the circuit that they measure the same load. The switch in the shunt circuit of the "standard" is then opened, and the reading of its disc and dial noted. When the disc of the "unknown" comes to the starting point, the shunt switch is closed, starting the standard, to which no further attention is paid by the observer. The requisite number of revolutions of the "unknown" is noted, and as it comes to the finish the switch of the "standard" is opened and its disc stopped. Disc and dial are again read, the difference between initial and final observations being the "standard revolutions," which, compared with those observed on the "unknown," give the error of the latter, without reference to the actual load on the two meters. Repeated observations under test have given duplication of results to within one-tenth of 1 per cent. on full load and one-half of

Digitized by Google

1 per cent. on one-thirtieth load. In practice, the "standard' is compared with a reference standard placed in the position of the unknown, the two operations of calibration and test being identical, and therefore eliminating any error due to sluggishness in the starting and stopping of the working standard. The reference standard is calibrated in the ordinary way by comparison with indicating instruments. The method has been experimented with for some time on a large system, and has given such good results that a number of instruments have been built and are in constant use.

Medical Electricians.—The last issue of the *Lancet* contains the following letter under the heading "Laymen and Electrical Treatment": "Sirs,—It is unfortunately the practice of many members of the profession to send patients whom they may wish to be treated by some form of electricity or the X-rays either to a layman for this purpose or to an institution owned and managed by laymen. In London, and in most of the provincial towns, medical men who practice entirely in electro and radio therapeutics are to be found, and yet these are time after time passed over, while specialists and general practitioners continue to send their cases to laymen for treatment. In some instances, no doubt, the medical man is not aware of the fact that he can procure all he wants for his patient in a legitimate manner, but I am sorry to say that he has not very often even this excuse for his conduct, and considers that by being present himself for the first two or three sessions he has done all that is necessary. The fact is that in sending patients to unqualified persons for treatment the medical men doing so are guilty of covering, and their presence during the sessions cannot, and does not, exculpate them from the onus of the charge. In order intelligibly to supervise any electrical or X-ray application, a vast amount of technical and practical knowledge is necessary, and the mere presence of a medical man, unless he is equipped with this knowledge, does not contribute to the safety of the patent or the success of the treatment. Now, sirs, in the interests of the profession and the public at large, it is very important that this part of medical work is not allowed to get into the hands of lay institutions entirely. One after another such institutions are springing up all over the country, and where the professional man has too often a difficulty in making both ends meet, they are like the green bay tree of Scripture, flourishing. By the encouragement and support given to them by medical men, vested interests are being established which will be extremely difficult to combat in the future. Electrology and radiology have advanced greatly of late; the death-knell of those dainty little boxes of brass and ebonite and mahogany, known to the public by the all-embracing term of 'battery,' and to the medical man as a faradic coil, has sounded; but there is still much to do, and it is a little hard on those who have worked to raise electrology to the dignity of a science in the eyes of the medical profession that they should meet with so little recognition from their professional brethren, and that the quack-loving peculiarities of the lay public should be manifest in the profession itself. At the present time I know of a large firm of chemists in London making several thousands a year by taking radiograms of patients, in most cases sent by medical men; and another firm who started to sell static machines and other electrical instruments, and who are now giving up the sale of these machines because they find it much more profitable to treat patients sent to them by medical men than to sell these goods. Surely this is a crying scandal, and deserves that every effort should be made to stop it." The letter is signed "Fair Play," but we doubt the applicability of the *nom de plume* chosen by its author. The letter shows the spirit of the old trade guilds during the worst period of their existence. Medical men evidently prefer to go to experts for electrical treatment for their patients, and rightly so. That these experts may not have doctor's degrees and knowledge is not a disadvantage, as this skill is supplied by the patient's own doctor.

Electric v. Steam Railways.—The chairmen of the various railways have recently had to explain to their shareholders the results of another half-year's working, and in so doing have referred to electric traction. These chairmen may be classed under three headings—*i.e.*, those who have anticipated competition from electric tramways and met it by electrifying their railway sections affected, those who suffer from competition while sitting on the fence, and, finally, those who still consider the steam locomotive better than its electric brother. In giving extracts from these speeches or reports in the above order, we commence with the North-Eastern Railway Company. This report says: The substitution of electric trains for steam trains for suburban passenger traffic on the Newcastle and Tynemouth and riverside branches has been effected during the half-year. The work has been carried out most efficiently, considering the novelty and difficulty of many of the practical problems which had to be solved in connection with the adoption of the new form of traction. A large increase has been made in the number of trains on the branches equipped for electric traction, and up to the present there is every indication that the results, both as regards revenue and convenience in working, will be satisfactory. Sir Charles Maclaren, M.P., presiding at the general meeting of the Metropolitan Railway Company, said they had completed their generating station, and cables and conductor rails had been laid, and the general equipment of the permanent way completed from Baker-street to Uxbridge. Similar work was being prosecuted each night upon the Inner Circle section and would soon be completed. All points of dispute between the company and the District Railway had now been settled, and the two companies were working together in a most friendly spirit. If the District Company were ready, he anticipated the new system would be in full working order towards the end of the year. Mr. Cosmo Bonsor, at the meeting of the South-Eastern Railway, remarked that this was the first time since the working union that they had shown an absolute decrease in the passengers carried. The amount of money involved was only £4,000 odd, but there was a decrease of 139,000 passengers. The fact was principally attributable to the electrification of the tramways in the metropolitan area. One station in the metropolitan district alone showed a decrease of 60,000 passengers during the half-year, and all the stations which were affected by the newly-electrified trams showed a considerable decrease. The amount of money did not mean much, but it was of sufficient importance to place upon the managing committee the obligation of seeing whether some of those stations which had been continued open for the convenience of the public, rather than for profit to the shareholders, could not now be closed. Lord Claud Hamilton, chairman of the Great Eastern Railway, said that, owing to the uncertainty of electric traction, the directors thought it advisable not to undertake any new schemes in regard to electrical traction before being fully satisfied as to their value. The directors had carefully watched what was being done by other companies, and, if possible, would profit by their example. They had been watching that portion of the Lancashire and Yorkshire Railway between Liverpool and Southport which was worked by electrical traction, and he, with several officers

Digitized by Google

of the company, had visited France for the purpose of ascertaining whether they could effect any alterations in the way in which their system was carried out.

British Association.—The Cambridge meeting of the British Association for the Advancement of Science promises to be an exceptionally interesting one. The fact that the Prime Minister (the Right Hon. A. J. Balfour, M.P., F.R.S.) is the president shows the close relationship between Imperial matters and science. The programme of local arrangements has now been issued, and from it one sees that the local committee have spared no pains to make the meetings a thorough success. The social functions are, if anything, more numerous than usual, and the business portion of the meeting is well arranged. It will be opened on Wednesday, Aug. 17, with the presidential address by the Right Hon. A. J. Balfour, which will be delivered in the Corn Exchange. On Friday, Aug. 19, there will be a lecture in the theatre by Prof. Geo. Darwin on "Ripple-Marks and Sand-Dunes." On Monday, Aug. 22, the lecture is to be delivered by Prof. H. F. Osborn, of New York, on "Palæontological Discoveries in the Rocky Mountains." The usual Saturday lecture to the operative classes will be delivered on Aug. 20 by Dr. J. E. Marr, F.R.S., on "The Forms of Mountains." The reception room in the Guildhall will be opened on Monday, Aug. 15. The programme of the various sections, as arranged up to the present, are briefly as follows: In Section A, on the Monday, Dr. R. T. Glazebrook will describe "Recent Work at the National Physical Laboratory." On Tuesday there will be a discussion on the "Radioactivity of Ordinary Matter," to be opened by Prof. J. J. Thomson; Prof. J. Larmer will read a paper on "The Relation between Röntgen Rays and Ordinary Light"; Prof. J. H. Poynting on the "Temperature Coefficient of *g*." In Section F, devoted to economical science, the presidential address will be delivered on Thursday, the 18th, by Prof. W. Smart to be followed by Prof. F. E. Edgeworth on "A Moot Point in the Theory of International Trade"; Prof. A. W. Flux, on "Improvements in Agriculture and their Effects on Economic Rent." The rest of the programme is as follows: Friday, Aug. 19—Mr. L. L. Price, "Economic Theory and Fixed Policy"; M. Yves Guyot, "The Incidence of Protective Duties"; Prof. W. Lotz, "The Effect of Protection on Some German Industries"; Prof. H. Dietzel, "Free Trade and the Labour Market." Monday, Aug. 22—Mrs. Bosanquet, "The Economic Importance of the Family"; Mr. H. McNiel, "Cotton-Growing in the Empire"; Prof. E. Mahaim, "Changes in Nominal and Real Wages in Belgium"; Mr. A. L. Bowley, "Tests of National Progress." Tuesday, Aug. 23—Mr. T. A. Baines, "The Distribution of Rural Population in India"; Mr. T. C. Horsfall, "The Housing Question"; Mrs. Fisher, "The Town Housing Question"; (possibly) Dr. Pierson, "The Housing Question." Wednesday, Aug. 24—Mr. C. T. Hamilton, "Trade Unions in U.S.A." (?); Mr. W. G. Adams, "The Modification of the Income Tax"; Mr. B. Ellinger, "A Proposed Substitute for the Sugar Tax"; Mr. H. A. Roberts, "The Employment of the Undergraduate." Date not settled—Dr. T. de Körösi, "Statistical Researches in the Mental Development of Girls and Boys." In Section L, which is devoted to education, there are to be informal discussions on important points rather than a series of papers by individuals. These subjects are as follows: (1) The school-leaving certificate of the Board of Education, University of London, and other examining bodies; (2) the national and local provision for training of teachers; (3) the methods of imparting manual instruction (in its broadest sense) in the various grades of schools. The above are specially arranged in view of the problems facing the new education authorities. (4) Lieut.-Colonel Mackinlay, "Realistic Arithmetic"; (5) Dr. R. W. Stewart, "The Place of Hemistic Method in Teaching Experimental Physics"; (6) J. H. Leonard, "Specialisation in Science Teaching"; (7) Report on "Influence of Examinations upon Teaching"; (8) Report on "Courses of Practical, Experimental, and Observational Studies in Elementary Schools."

Tramways and Depreciation.—In our issue for last week we referred to the able speech of Alderman J. A. Godwin, the chairman of the Finance Committee of the Corporation of Bradford, which had improved the financial policy of the Corporation. The following extract from the speech is worthy of full repetition in our columns, as it deals with a much debated matter. Speaking of tramway depreciation, Alderman Godwin said: "The question of depreciation had engaged a considerable share of attention in connection with the financial success of tramways and other municipal undertakings, and upon this question there were divergences of opinion and a variation of practice. The evidence put before the recent Royal Commission on Municipal Trading revealed the fact that even among experts there were two schools of thought. These might be broadly distinguished as the advocates of the English and Scotch systems. The distinction, so far as the Scotch method was concerned, is mainly credited to Glasgow, where, to some extent by the force of circumstances, they were practically tied down to the adoption of a method which, whether it received the assent of the judgment or not, had come to be regarded as part of their municipal creed. The very large income—although the stages were only ½d.—and the favourable character of their gradients, with other fortunate local conditions, produced such a surplus as enabled Glasgow not only to provide for repayment of debt within the prescribed period, and to repair and renew the plant, so that it was always kept up to practically its original value, but, in addition, to put aside such a further sum as would purchase a new tramway undertaking at the end of the sinking fund period. That was practically building up a reserve fund out of the pockets of the present generation which would be sufficient to provide for the next generation a system of tramways or other means of locomotion free of cost. That might be broadly described as the Scotch method, and it found certain advocates. Over and against this it was contended that the method adopted by the majority of English municipalities of providing for repayment of debt within the prescribed period, while keeping the undertaking in proper working condition and providing a fund for contingencies, was quite as much as could be demanded from the users of the tramways, either from a legal or a moral point of view. Where the reserve fund was sufficient to renew portions of the plant which periodically wore out, and where the daily wear and tear could be repaired out of revenue, and the statutory provisions as to sinking fund were adhered to, it appeared to him that neither in law nor in equity was a corporation called upon to do more. The Bradford tramway undertaking had been able to accomplish all this during the past year. The income had been £197,438; the working expenses, which included renewals and repairs, were £137,932, leaving a trade profit of £59,506, representing £7. 19s. 10d. per cent. on the productive capital invested, which was £744,431. The interest and sinking fund absorbed £46,106, leaving a net profit of £13,400. This it was proposed to utilise by wiping off the suspense balance of £10,483 in respect of the amount paid to tramway companies as surrender value of unexpired leases, and to carry the remainder, £2,917, to the depreciation of plant account. It was possible that

Digitized by Google

objection might be taken to the apparently small sum which had during the last year been set aside for purposes of depreciation—namely, £2,917—as against £7,747 the year before and £10,015 the year before that, but he wanted to show that the Council could scarcely be expected to expend large sums in upkeep, renewals, repairs, and so on, and in addition provide a fund which would do the same thing over again. If the amount for depreciation was limited to a provision for contingencies and wear and tear which could not under any possible circumstances be met day by day out of revenue, that surely was the extent to which it could fairly be expected to apply. And it might fairly be said that if the amounts spent on repairs and renewals showed an increasing percentage upon the capital outlay, then the amount required for depreciation purposes should diminish in a similar ratio. In other words, if the two sums were added together and the percentage of their total upon capital was seen not to be in a diminishing ratio, then an equal provision for renewal and replacement purposes had been made. During the year ended March 31, 1902, the amount expended upon repairs and renewals was £11,900, and £10,015 was set aside for depreciation, the total giving a percentage on working capital of 5·22. In 1903 the expenditure under these two heads was £32,521 and £7,747 respectively, or 6·13 per cent., and in 1904 it was £40,233 and £2,917, or 5·79 per cent.

Wireless Telegraphy Bill.—The following memorandum explanatory of the Wireless Telegraphy Bill, introduced by Lord Stanley, the Postmaster-General, has been issued as a parliamentary paper [271]: "The development of wireless telegraphy during the past few years and the prospect of its further development and extended use in the near future have rendered legislation on the subject essential in the interests of the naval and military requirements of the Empire. In any future war, especially in a naval war, wireless telegraphy will, probably, play a very important part, and it is essential that the control of this method of communication should be in the hands of the Government. At present, the Governments of nearly all the great Powers and most of our self-governing Colonies have control over wireless telegraphy both for inland and foreign messages, but, except in the case of messages between two points in the United Kingdom and in territorial waters within the three-mile limit, the powers of his Majesty's Government are limited and inadequate. In time of war or emergency, the Government can take possession of the telegraph stations of incorporated companies carrying on telegraphic business, but the power does not extend to the installations of private individuals. The Postmaster-General can also impose conditions in connection with the arrangements for the transmission of foreign telegrams over the postal wires; but advantage could only be taken of this power where facilities for transmission were required, and this, obviously, might not be the case in connection with many installations of danger to the State. Otherwise, the only means of control possessed by the Government are furnished indirectly by an arrangement which has already been made in a number of instances with foreign Powers, by which those Powers undertake not to permit the establishment of systems of wireless telegraphy for communication between their own territory and the United Kingdom except after previous consultation with the British Government. An arrangement of this nature is obviously unsatisfactory and insecure, especially from the point of view of defence, and in time of war or strained relations would give rise to difficulties of a grave and far-reaching nature. It would at such times be of vital importance to prevent unauthorised information leaving this country, and, further, to secure uninterrupted communication between his Majesty's fleets and vessels and shore signal stations. Legislation is therefore needed for the following reasons: (1) The extreme importance in time of war or emergency of exercising control and supervision of all means by which information could be conveyed to an enemy, and of preserving such secrecy as to plans and preparations as is essential for successful operations. It is not a matter of great difficulty for a private individual to set up a temporary installation on his own property. This might, for a time, escape observation, but, if situated near the coast, would be a source of great danger in time of war, as it would not only be able to intercept messages from neighbouring stations, but might further be used for communication with unauthorised persons and the disclosure of naval and military arrangements. (2) One of the great difficulties to contend with in wireless telegraphy is interference as between neighbouring stations, and this must be met by limitation of the number of stations and careful selection of sites. If the number of installations were greatly increased and they were set up without regard to strategic requirements, the interference might easily be so great as to minimise the usefulness of wireless telegraphy for communication with his Majesty's ships. This consideration has especial weight in relation to times of war or emergency. (3) In time of war or emergency it is important that the Admiralty should at all times be able to communicate with his Majesty's ships, and with this view the Government should have power of stopping absolutely the use of wireless telegraphy in private hands when its use would interfere with such communication. Thus, from the point of view of strategic requirements, three of the most important points to be considered are: (*a*) control of the transmission of messages; (*b*) prevention of the establishment of unauthorised stations; (*c*) disposition of stations in the most advantageous way so as to obtain the best results in working, free from interference, accidental or intentional. It is only by means of legislation, and, preferably, by the licensing of stations, that these points can be secured. In addition to the above imperative reasons, there are others which render legislation for the control of wireless telegraphy very desirable. Proposals have been made for an international agreement to regulate wireless telegraphy in certain respects. Since international relations are concerned with wireless communication between stations in this country on the one hand, and ships on the high seas or stations in other countries on the other, it is desirable that the Government should be in a position to enter into an agreement on the subject with other countries, if it should be found expedient to do so. In the present state of the law there would be no means of enforcing the conditions laid down by such an agreement. Further, in order that the invention may be developed and applied with the greatest advantage to the public, it is desirable that matters such as the position of stations, and their interference with one another, should be regulated in the general interest. It is proposed in the Bill, for reasons of administrative convenience, that licenses should be granted by the Postmaster-General, since the Post Office is the department which deals with telegraphs in general, and is in relation with foreign telegraph administrations. On the other hand, it is provided that licenses shall not be granted except with the consent of the Admiralty and War Office, thus securing that the strategic considerations, which are of paramount importance, shall be regarded. As the progress of wireless telegraphy also affects the trade and commerce of the country, it is proposed to add the Board of Trade as a consenting party to the grant of a license.

NORTHAMPTON CORPORATION ELECTRIC TRAMWAYS.

In 1902 the Corporation decided to convert the horse tramways to electric traction, and in May, 1903, instructed the borough engineer, Mr. Alfred Fidler, A.M.I.C.E., to prepare a complete scheme for the reconstruction of the existing permanent way, together with the construction of the authorised extensions; also the erection of a power

ALDERMAN WOODING, CHAIRMAN TRAMWAYS COMMITTEE.

station, generating plant, car depôt, overhead equipment, underground feeders, cables, and tramcars. In September, 1903, tenders were accepted for the various sections of the work, and shortly afterwards the various works were commenced.

Permanent Way.

The route length is about 5½ miles, equal to about nine miles of single track. The work comprised under this section consisted of the reconstruction of the existing tramways and the doubling for the greater part of the

J. GOTTSCHALK, ESQ., GENERAL MANAGER.

length No. 1—from Franklin's-gardens, St. James End, to the Drapery; No. 2—from the Drapery, along Abington-street and Kettering-road, to the terminus opposite St. Matthew's Church; No. 3—commencing at Abington-square, along Wellingborough-road, to the northern entrance to Abington Park; No. 4—commencing at the Drapery to the top of Sheep-street, with double line, thence along Sheep-street, Barrack-road, and Kingsthorpe-road, to the terminus at the junction of Harborough-road and Walford-road, single line with passing places.

The actual commencement of the work was made in January, 1904, and over several portions of the routes the traffic on the existing tramways was continued. At the present time the whole of the sections are completed with the exception of the Kingsthorpe section, which it is expected will be completed before the end of the month. For various reasons it was decided to maintain the existing gauge of 3ft. 6in. Where found to be sound, the existing concrete foundations were used, and for all new foundations cement concrete of the proportions of five parts

A. FIDLER, ESQ., BOROUGH ENGINEER.

of broken stone, one part of sand, one part of Portland cement was used. The rails are of the girder type, 6½in. deep, weighing 90lb. per yard for the straight rails and 96lb. per yard for the curved rails, and the fishplates weigh 50lb. per pair, having six bolt-holes.

The rails and fishplates were supplied by the North-Eastern Steel Company, Middlesbrough. Mild-steel tie-bars were used, and at each rail joint and midway in the length of the rails Anchor soleplates were used to secure the rails to the concrete foundations. The points and crossings were

J. MC'MAHON, ESQ., ELECTRICAL ENGINEER.

manufactured by Messrs. Askham Bros. and Wilson, of Sheffield; they are of cast crucible steel with forged steel tongues. The movable points are of the automatic spring type, and are interchangeable. The points are 12ft. in length and the crossings are of the iron-bound type, the arms being of similar rail section securely embedded in the castings. The rails are drained where necessary by means of drain boxes discharging into adjacent branch drains. The rails are bonded at every joint with protected copper bonds, the cross bonds being of solid copper of the Neptune

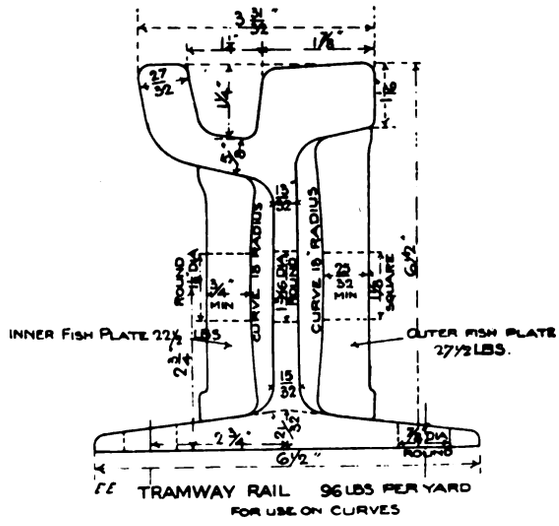
Digitized by Google

type. The permanent way is paved partly with Norwegian granite setts, and for the remainder with the old setts taken

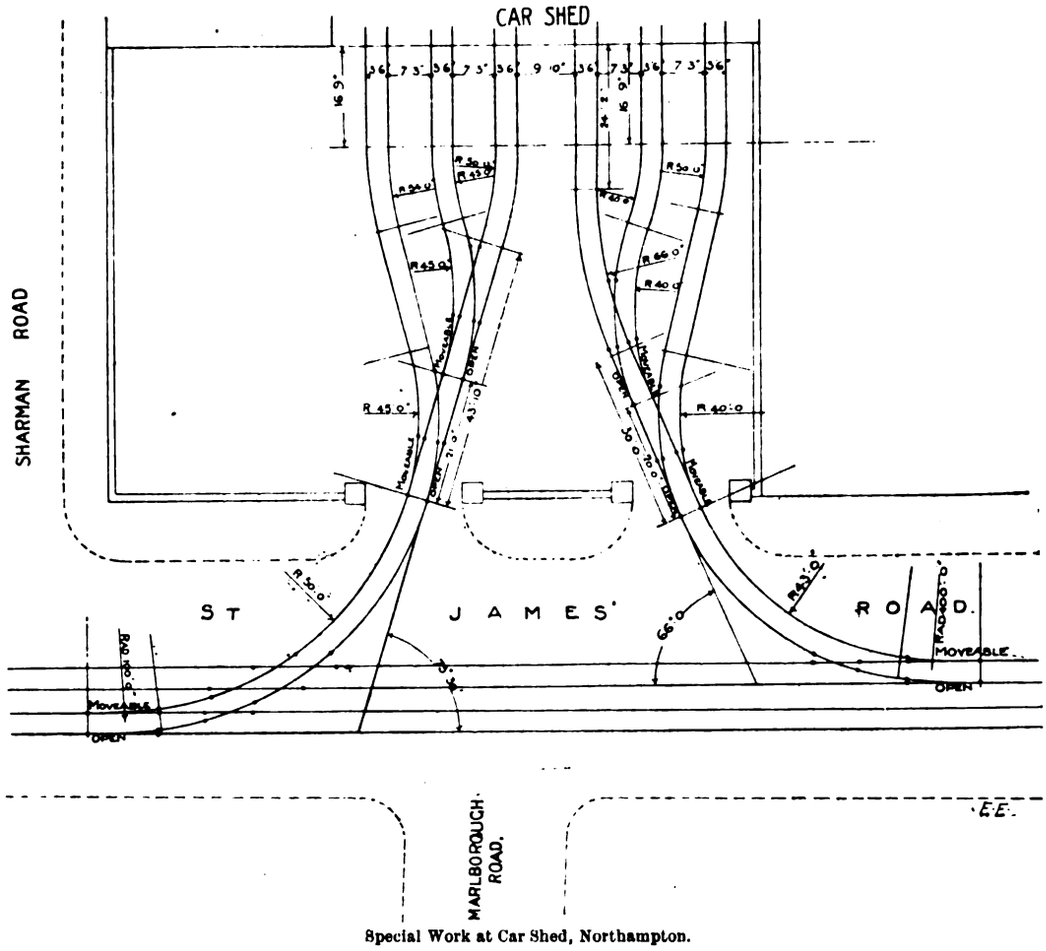
Town Hall, Northampton.

up from the existing tramways and re-dressed, the joints being grouted with Portland cement and sand.

in Castle-street in order to utilise the steam raised by the destruction of the town refuse by the dust destructor, the central position of which enabled a more economical distribution of current throughout the system. The engine-room is 63ft. long, 40ft. wide, and 22ft. 3in. high to the tie-rod of the roof trusses. The boiler-house is 46ft. 3in. long, 38ft. wide, and 14ft. 6in. high. These measurements are over all, and include pump-room, mechanical draught room,



and accommodation for coals. The storeroom is 38ft. long and 18ft. 7½in. wide. A similar space is devoted to the mechanics' shop and engineer-in-charge. Over these rooms is the battery-room, 38ft. long and 38ft. wide and 9ft. high to the tie-beam, with steel and concrete composite floor. The engineer's office, general office, and testing-room are each 12ft. by 12ft. 5in. by 14ft. high. There are two sets of bathroom and lavatory accommodation, 18ft. 6in. by 10ft. 10in. over all. The exterior of the building is of



Special Work at Car Shed, Northampton.

Power Station.

From economical motives it was decided to erect the power station upon ground adjacent to the refuse destructor

selected brickwork, with terra-cotta and stone facings, blue Staffordshire brick dado and plinth. The engine-room floor is laid with red tiles diagonally. The engineer's office floor

is laid with wood blocks. The roof of the building is covered with Mellowes patent glazing, and the portions near the eaves are slated over diagonally-laid boarding.

STEAM-RAISING PLANT, ENGINES, DYNAMOS, ETC.

The existing plant at the refuse destructor consists of two Lancashire steel boilers, 30ft. long and 8ft. diameter, suit-

Digitized by Google

able for working to 160lb. pressure, with a Green's economiser for feed-water heating. The steam-raising plant in the new power station consists of two boilers of the Economic type, each capable of evaporating 8,000lb. of water per hour, and made by Messrs. Davey, Paxman, and Co., of Colchester. The boilers are fitted with mechanical stokers of the Bennis type, and superheaters are placed in the boiler flues capable of superheating the steam to 500deg. F. The boilers are fitted with an induced-draught plant provided by two motor-driven fans and a steel stack. The feed pumps are of the Weir type, and the steam-valves are of Messrs. Templer and Ranoe's make. The steam-piping provides for the coupling of the two Lancashire and the two Economic boilers.

The condensing and cooling plant consists of a Mirrlees-Watson condenser, capable of condensing 12,000lb. of steam per hour. The centrifugal circulating pumps and an Edwards air-pump are motor-driven. The cooling tower is of the Klein type, about 70ft. high. It is of timber, and of the natural-draught type, resting on a brick-faced concrete tank about 22ft. by 32ft. by 7ft. deep. A Paterson water softener and oil separator are provided to deal with the make-up water and the oil after the water leaves the condenser. The water supply will be obtained from the town supply and from a well sunk on the site.

The generating plant consists of two 200-kw. sets, composed of Willans compound three-crank engines running at 300 revolutions per minute, and capable of giving 360 i.h.p, and International Electrical Company's dynamos; also one compound set capable of giving an output of 120 kw., and consisting of a Willans two-crank compound engine running at 350 revolutions per minute, capable of giving 240 i.h.p., and a dynamo of the International Electrical Engineering Company's make. The battery was made by Messrs. Ashmore, Benson, and Pease,

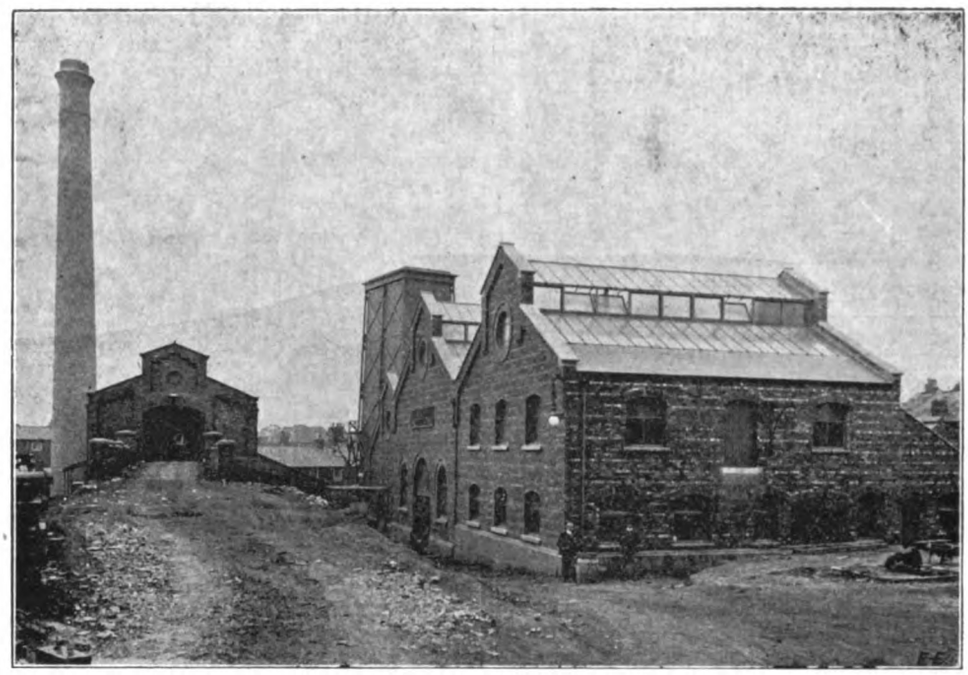
Digitized by Google

of Stockton-on-Tees. It consists of 250 cells, and is capable of giving out 170 amperes for three hours. There is also provided a reversible booster and milking set, both made by the International Electrical Engineering Company.

The switchboard has eight panels of white marble mounted on a steel framing carried on a wooden platform. The panels carry the necessary circuit breakers, ammeters, lightning arresters, voltmeters, wattmeters for the recording and control of the current generated. In the engine-room there is an overhead travelling crane of 40ft. span, capable of lifting 10 tons, made by Messrs. Jessop and Appleby, of Leicester. The power station is lighted throughout by electric light.

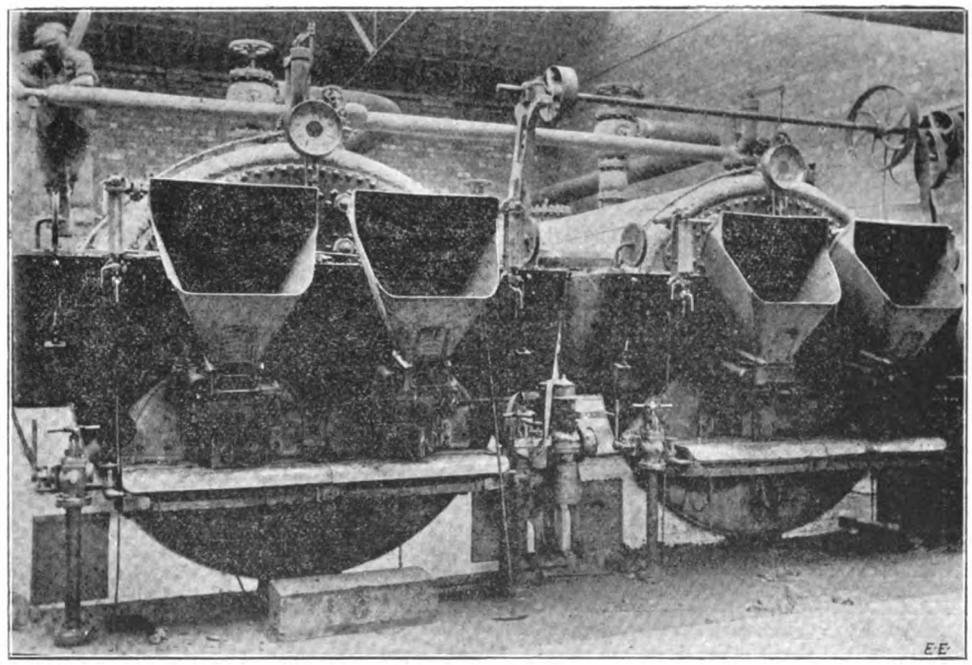


The Generating Station for the Northampton Electric Tramways.

Overhead Equipment.

The overhead equipment is to a great extent on the span-wire principle, with bracket-arm construction in the narrow streets. The poles are of lap-welded steel in five sections, telescoped into each other, and have an ornamental wrought-iron base bearing the borough coat-of-arms. The span-wire poles have curved wrought-iron scrollwork, and the bracket arms have ornamental iron scrollwork supports. Each pole is capped with an ornamental finial. All poles are embedded in the ground to a depth of 6ft. and rest on a concrete base, and are surrounded with concrete up to the underside of the pavement. Double trolley wires are fixed throughout the whole of the system. The wire is hard-drawn copper, No. 000 B. & S. gauge. All frogs and crossings are of gunmetal, and the span and guard wires are of galvanised steel.

The feeder pillars are arranged at half-mile intervals, and consist of cast-iron boxes containing enamelled slate panel, upon which are mounted the necessary switches and lightning arresters, etc., and opposite each feeder pillar on the overhead wires there is a sectional insulator, which divides the overhead line into corresponding half-mile sections, which are fed on either side of the insulator from the feeder pillar. The overhead system is arranged generally for normal central running, excepting the side-arm bracket construction, where it is on the average 4ft. from the centre of the track.



The Northampton Boiler Room—Davey-Paxman Economic Boilers and Bennis Stokers.

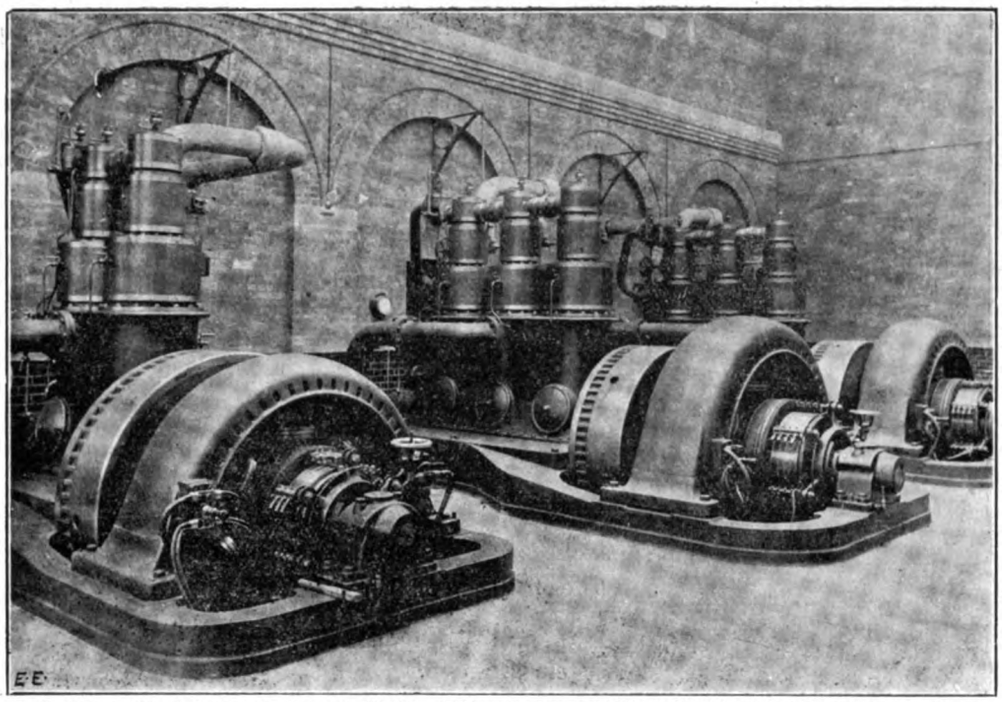
The current is conveyed to the various parts of the system by means of lead-sheathed cables laid on the draw-in system in Sykes stoneware multiple conduits. The pilot wires for the return current from each terminus to the

Digitized by Google

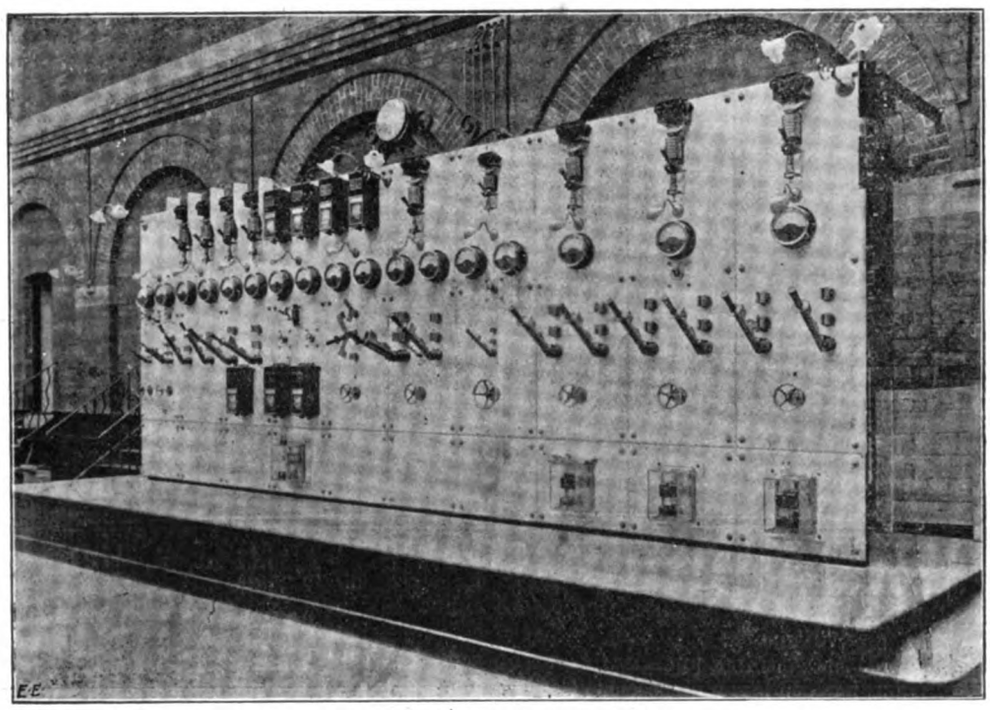
generating station and the telephone wires are carried in three-core lead-sheathed cables in ducts as far as the feeder cables, and laid on the solid system for the remainder of the lengths.

CARS.

There are 20 cars of the following dimensions: length of car body, 16ft.; over-all length, 26ft.; total over all-width, 6ft. 4in. They are all of the single-truck double-deck type. The framing is of oak, the flooring of pine, the dashers of steel plates, the stairway stringers of sheet steel firmly bolted to the car body and platform. The handrails are of brass tubing. The collision fender round the platform is of steel section. The waist panels are of mahogany, and the roof framing is of ash. The ceiling of the cars is of three-ply maple veneer. The upper deck is of pine, and is provided with wearing slats. The railing round the upper deck is formed of polished brass tubes filled in with strong wire screens. The doors are of oak with handsome carved panels. The seats are of perforated veneer, and special provision is made for thoroughly ventilating the cars in the interior. The cars are provided with an effective system of lighting, with head lights, signal lights, and lights for the destination indicators. The cars are handsomely finished in an artistic fashion, the waist being a rich crimson with gold-panelled borders, the remainder of the body being cream. The trucks are of the Brill type; the wheels are of chilled iron, 2ft. 6in. in diameter, and hand-brakes and slipper brakes are provided. At each end of the car an automatic safety guard of the Hudson and Bowring type is fitted. This consists of a hanging gate, which, on meeting an obstacle, flies back and releases a sloping gate in front of the wheels, and drops to the ground, and prevents any body which might be on the track from reaching the wheels. The lifeguard remains down until released by the driver. There are two motors fixed to each car, each of 27 h.p. rating. The gearing between the motor and the axle consists of pinion and spur wheels enclosed in a cast-iron oil-tight gear case, the gear running in an oil bath. A new feature introduced into the cars is the steps. These are made of steel frames,



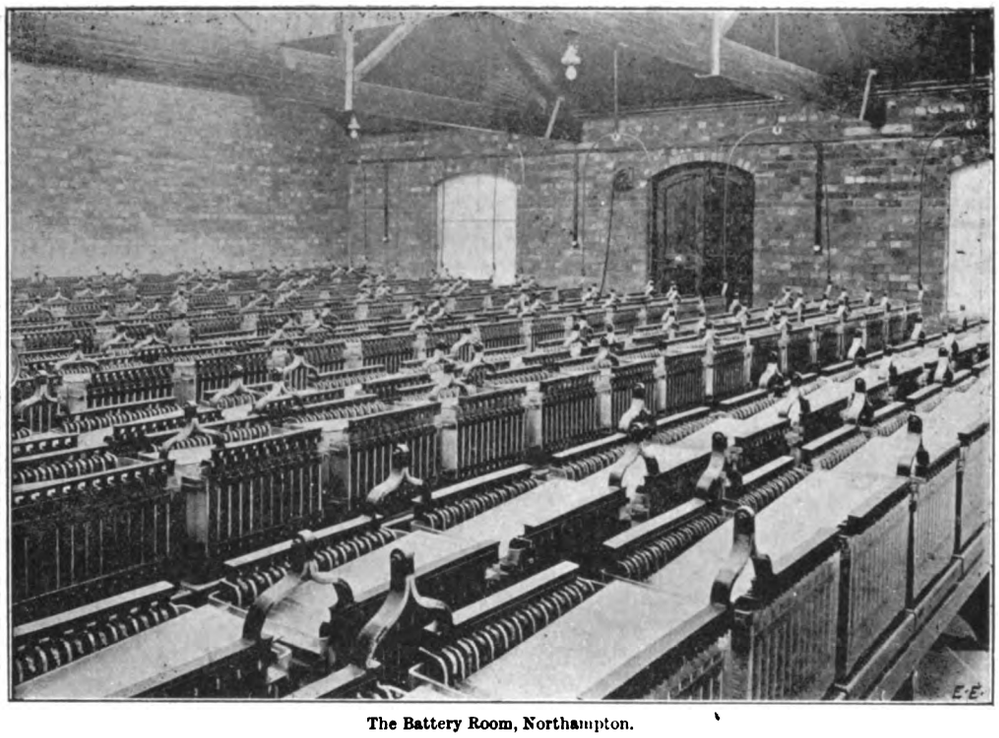
The Engine Room of the Northampton Tramway Station—Willans Engines and International Electrical Engineering Co. Dynamos.



The Switchboard, Northampton.

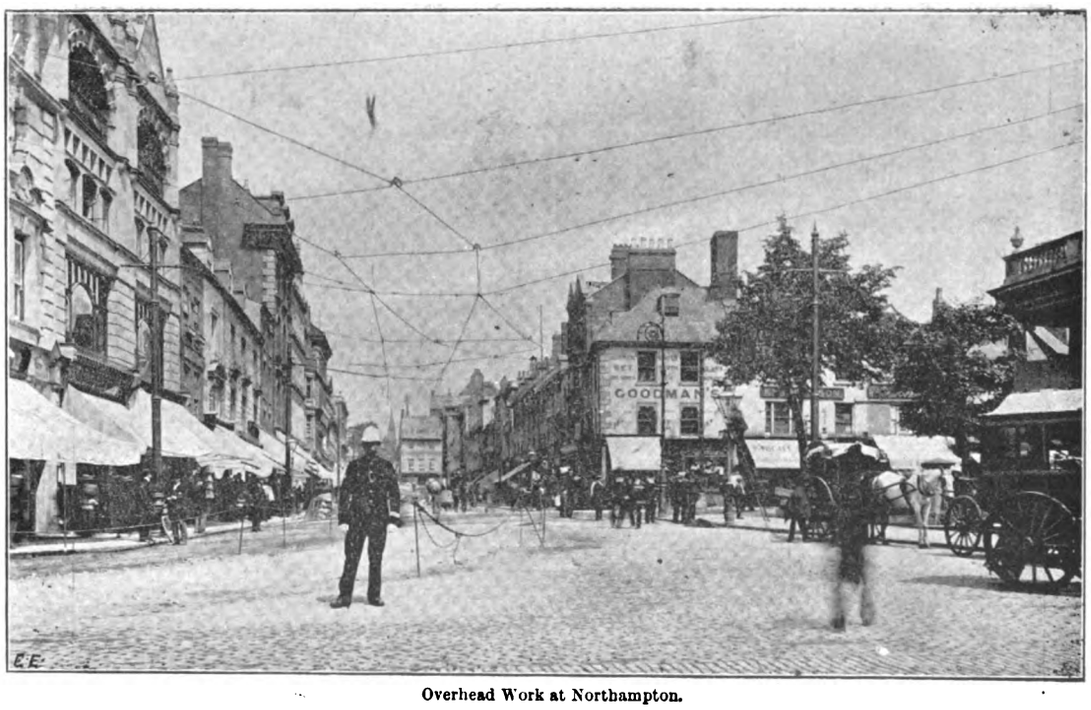
Digitized by Google

filled in with lattice work. The step can be folded by means of gearing worked by a ratchet, which also secures and locks the platform gate at the same operation. The steps at the driver's end are so arranged as to be always folded. This type of step prevents any projection from the front of the car. A controller is placed on each platform of the series-parallel type, and is arranged so that the main controller can be interlocked with the reversing switch.



The Battery Room, Northampton.

The mast carrying the trolley arm is of the enclosed spring type, the top of the mast being 5ft. 5ft. from the crown of the car. The trolley arm is of steel tube tapering from 2in. at the base to 1in. at the top. The trolley head is of the swivel type, and is insulated from the arm. The arm is also insulated from the mast.



Overhead Work at Northampton.

Car-Shed.

The main building is 150ft. long and 68ft. 10in. wide and 10ft. high to the tierod, and will accommodate 30 cars. The general office, manager's office, stores, carpenters' shop, repair shop, and smithy adjoin the building, and are 15ft. wide and of varying length. Next these shops, etc., is the yard for general stores, and is 140ft. long and 20ft. wide, in which is placed the lavatory accommodation. The shed is divided into six bays, and a pit extends the whole length under each bay except a short length for door opening, etc. Each pit is drained. The steel roof is supported with steel stanchions, 24ft. apart, at each end of which is a rain-water down pipe and a stand-pipe, etc., for car-washing. The yard in front of the building is 75ft. long and 106ft. 2in. wide. The building is treated similar to the power station on the elevation.

The contractors for the various sections were as follows: boilers, condensing plant, etc., the British Westinghouse Electric and Manufacturing Company, Manchester; steam generators, dynamos, battery, etc., the International Electrical Engineering Company, London; the overhead trolley equipment, the Brush Electrical Engineering Company, Limited, London; underground feeder cables and pilot wires, Messrs. Siemens Bros. and Co., Limited, London;

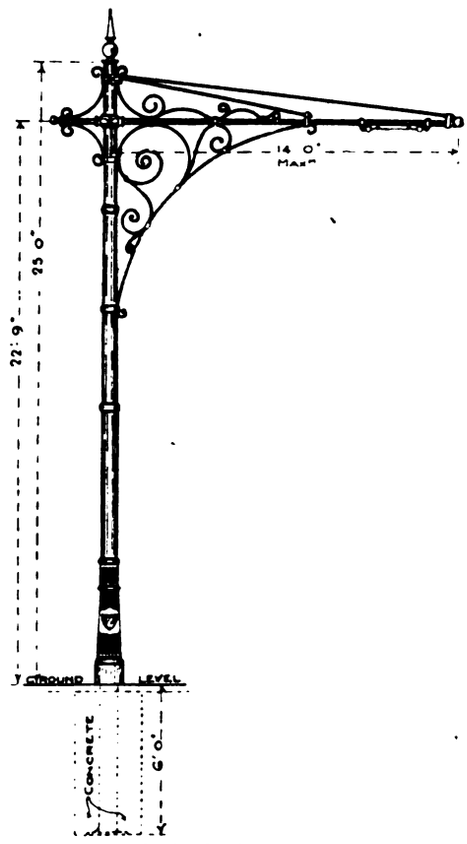
Erecting the Overhead Wires at Northampton.

cars, Messrs. Dick, Kerr, and Co., Limited, Preston; permanent way, Messrs. J. G. White and Co., Limited, London; power station, W. Beardsmore, Northampton; car-shed, Messrs. Watkin Bros., Northampton.

The scheme has been prepared and carried out by Mr. Alfred Fidler, A.M.I.C.E., borough engineer, and the following members of the borough engineer's staff have assisted in the execution of the scheme: Mr. J. McMahon, A.I.E.E, as resident electrical engineer; Mr. A. W. Ward,



Pole for Overhead Work.

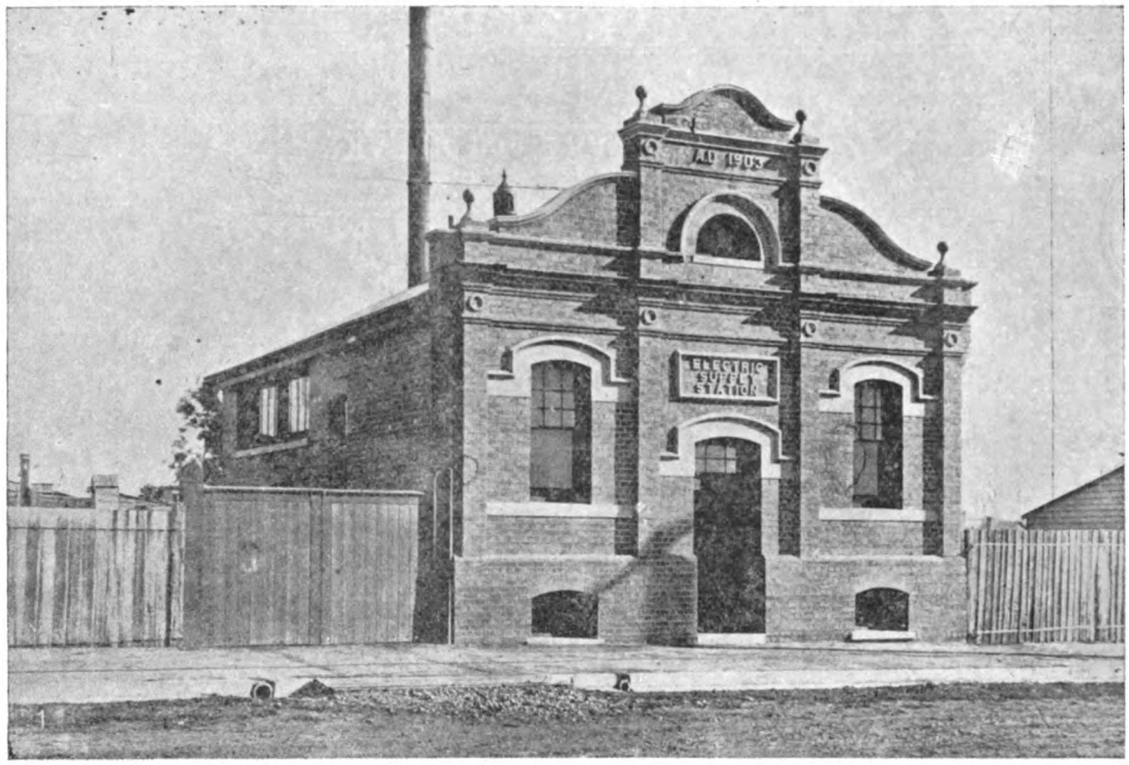
A.M.I.C.E., as superintendent of the permanent way; Mr. S. Wilkinson, as superintendent of the erection of the power station and car-shed. The whole scheme has been carried out without the aid of an outside consulting engineer.

ELECTRIC LIGHTING OF DEVONPORT, TASMANIA.

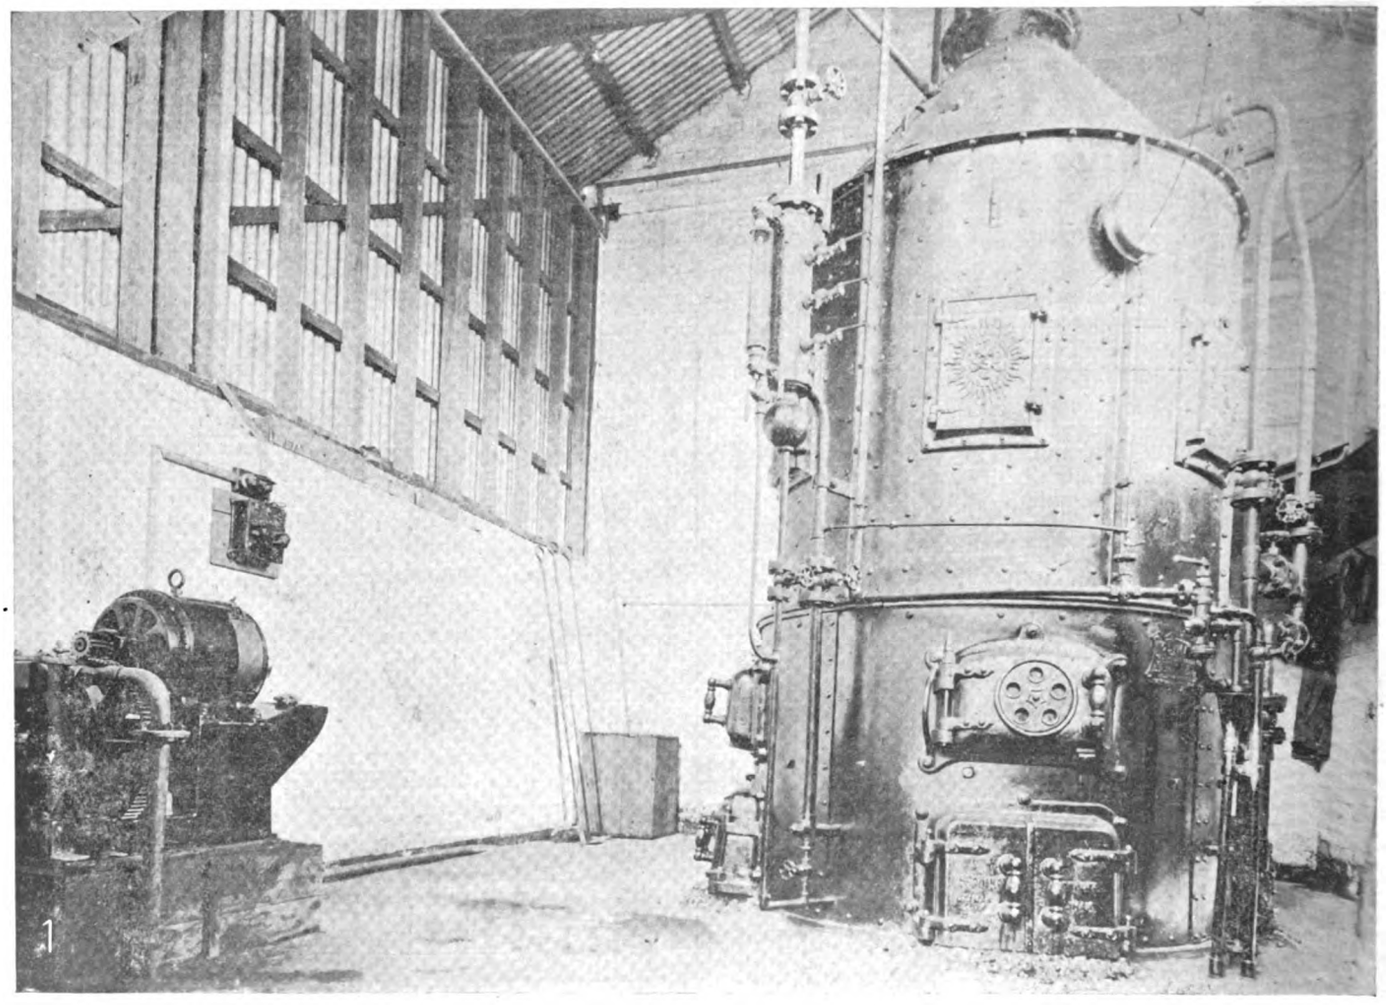
There are few towns in the United Kingdom of population less than 5,000 that can boast of an electric light supply of their own. An instance of what has been recently

Digitized by Google

accomplished in a small town in far-off Tasmania may therefore be not uninteresting to our readers. Very hazy notions exist in the minds of many English people as to where Tasmania is. It is thought to be somewhere in Australia or New Zealand; it is known chiefly by the Tasmanian apples with which the London market is regularly supplied for three months of the year; and the natives are supposed by some to be black people, by others to be the descendants of those who in days gone by were granted a free passage at His Majesty's expense, usually for some trifling misdemeanour, to Van Diemen's land as Tasmania was then called.



Exterior View of the Power House at Devonport, Tasmania.

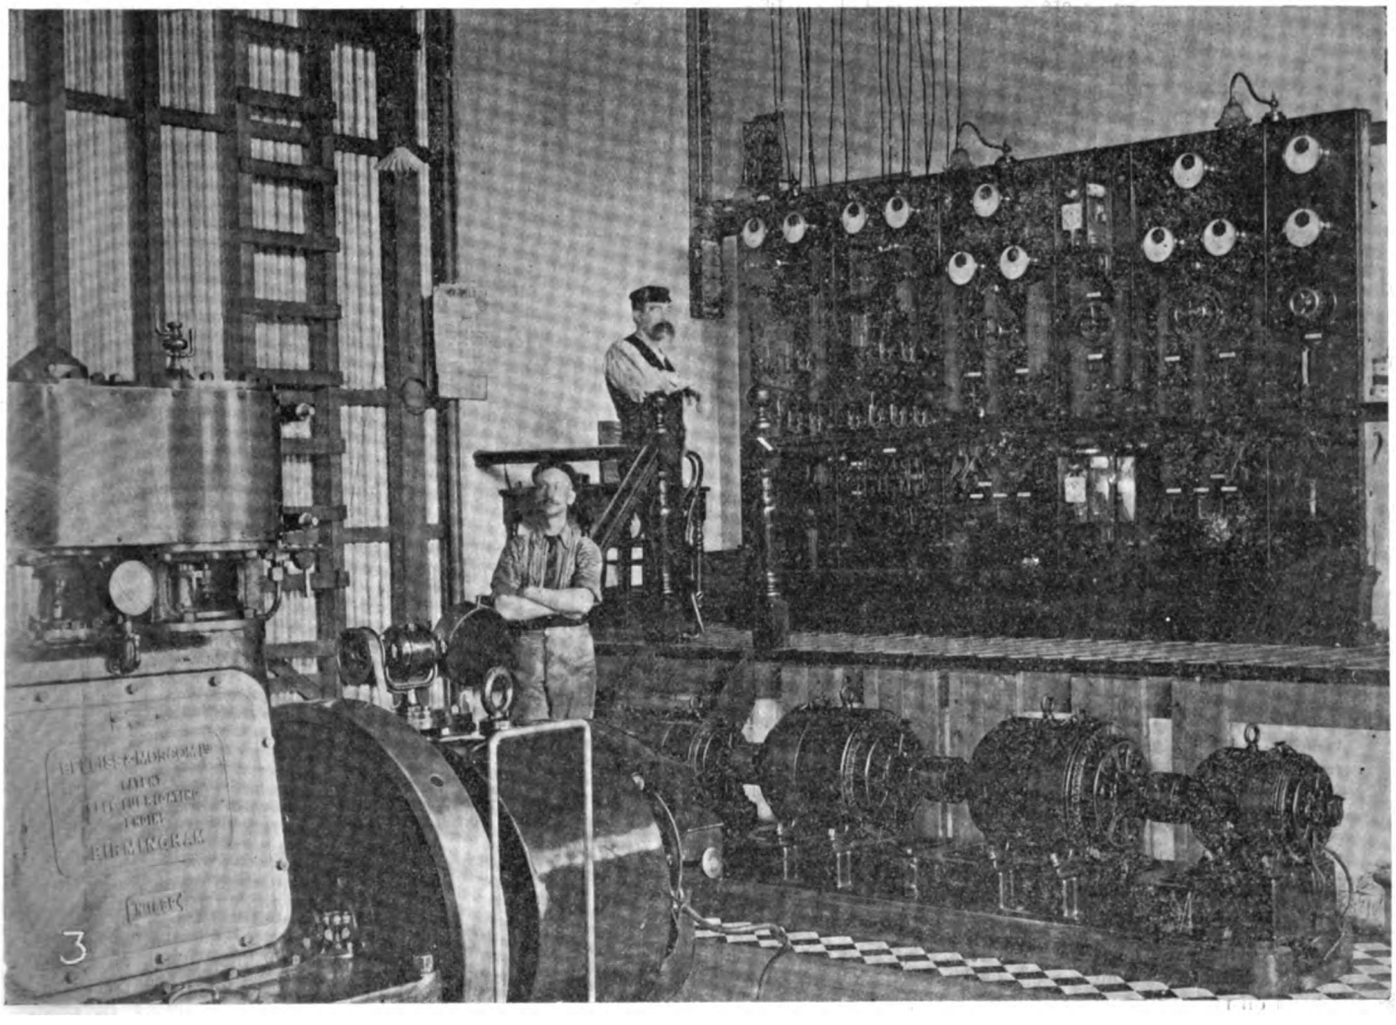


The Boiler Room at Devonport, Tasmania, with Climax Boiler.

Digitized by Google

Actually Tasmania is the smallest of the States of the Australian Commonwealth. In its insular position and its proximity to the neighbouring continent, from which it is distant about 100 miles to the south, it offers a close analogy to the parent country, that "precious stone set in the silver sea," and like it, compared with the mainland, its equable climate and luxuriant vegetation combined, proclaim it another "Eden, demi-Paradise." The P. and O. and Orient mail steamers call regularly at Hobart, in the south of the island, during the apple season, which lasts about three months, and each week there are shipped from 20,000 to 30,000 cases of apples, each holding about 50lb. Recently a movement has been set on foot for the establishment of a deep-water port for Northern Tasmania, and Devonport is now vieing with the neighbouring city of Launceston to secure the distinction.

The town is situated on both sides of the River Mersey, which affords a safe anchorage for the largest vessels afloat.



The Engine Room, with Belliss Engine, Brush Dynamos, and Dorman and Smith's Switchboard.

Five years ago the population was only 1,800, and the Town Board's annual assessment £7,000; to-day the population approaches 5,000, and last year's assessment was over £17,000. That this expansion is likely to continue is evidenced by the number of new buildings, including a handsome brick church and a large hotel, now in course of erection. The town possesses a reliable water supply, and has just been furnished with a modern electric lighting equipment.

The Town Board is composed of smart and progressive business men, and to their zeal in its interest this latest undertaking is due. Two years ago the Board, after careful enquiry and the consideration of much expert and other evidence, unanimously decided to instal a system of electric supply suitable for public and domestic lighting and for the supply of power. The Board obtained the services of Mr. William Corin, A.M.I.C.E., M.I.E.E., once with the Metropolitan Electric Supply Company, but for the past eight years city electrical engineer of Launceston, Tasmania. Mr. Corin's first scheme provided for supplying the whole of West and East Devonport, but owing to a certain amount of opposition it was thought wise to commence by driving in the thin end of the wedge, and hence a diminutive scheme for supplying only the principal streets of West Devonport was adopted. Tenders were then called and contracts let, the Brush Company supplying the main part of the generating plant, Mr. T K. Steares, representing the Tudor Battery Company, receiving the contract for the accumulator. Contracts for the building and for wooden poles and arms were let locally. The Board subsequently appointed Mr. Geo. H. Lofts as their town electrical engineer, to act as clerk of works during construction, and to take over the control when completed.

Direct-current, three-wire, 440 volts across outers, with accumulators, is the system adopted. A 70-h.p. Morin's patent "Climax" boiler, by Rowland and Co., of Reddish, supplies steam to a 48-kw. direct-coupled set, the engine being by Belliss and Morcom, and the generator being a four-pole "Universal" Brush machine, with Mordey "chord" winding. The battery consists of 240 L E 7 Tudor cells, and a balancing and boosting set, also of Brush manufacture, is provided, the four machines being direct-coupled. The switchboard, by Dorman and Smith, was supplied by the Brush Company, as also was an electrically-driven feed pump of the "Hatfield" type, by Merryweather and Sons. A complete set of Weston instruments for standardising purposes is provided.

The building was entrusted by the consulting engineer to his colleague, Mr. C. St. John David, M.S.E., city engineer and surveyor of Launceston, Tasmania. It is of Queen Anne design, and is built in red brick, with a temporary side so arranged as to allow for extensions. The whole plant is laid down with this in view, and the switchboard, perhaps unnecessarily complicated for the present small area and small load supplied, will be sufficient for supplying the whole of East and West Devonport in the

Digitized by Google

future. The building will accommodate one additional set similar to the present one, and by extending it northwards room may be provided for three more sets. But before this is necessary, if Devonport continues to grow, it is probable that a water-power transmission scheme may be adopted, which will make a large supply available, and in this respect Devonport will follow the example set by Launceston, where new plant, by Kolben and Co., to the extent of 1,200 kw. is now being erected. The consulting engineer was, however, unable to advise commencing the Devonport supply with water power, owing to the small initial demand contemplated and the heavy capital expenditure involved. With steam power, on the contrary, a balance of a few pounds to credit is shown on the first complete quarter's running.

Owing to the policy advocated by the consulting engineer, and adopted by the Board—viz., to undertake the wiring of houses on the hire-purchase system, or, if desired, to put in the wiring for 10 per cent. rental per annum—a nearly full load of 3,000 lamps was waiting for the plant before it commenced to run; and now, after eight months' running, a poll of the ratepayers has decided by a two-thirds majority to increase the loan from £7,000 to £11,000—*i.e.*, the full extent of the parliamentary powers obtained by the Board—in order to provide funds for the duplication of the plant.

The mains are all overhead, and the street lamps are suspended from ornamental iron brackets. With one exception, there is nothing particularly novel about the outdoor work; that exception is the method adopted for changing over from arc to incandescent lamps, which, so far as we are aware, has not been employed before, the idea being due to Mr. Corin. At present, in addition to 29 incandescent lamps of 25 c.p. each, there are only 10 enclosed arc lamps, 10 more incandescents being arranged to take

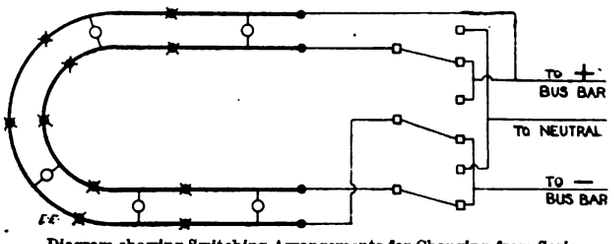


Diagram showing Switching Arrangements for Changing from Series Enclosed Arcs to Incandescent Lamps at Devonport, Tasmania.

their place when desired. The method of switching either the one or other set of these on is shown in the accompanying diagram. The arc lamp circuits are arranged as a pair, each with five lamps in series, and the alternative incandescent lamps are connected across the circuits, as shown in diagram. With the arc lamps running, the two circuits are in parallel across the outers. By means of a three-pole double-throw switch, both ends of one circuit are connected to either the positive or negative 'bus bar, and both ends of the other circuit to the neutral 'bus bar; with this arrangement, when the incandescent lamps are alight, they are all on the positive or negative side of the circuit; but with four circuits comprising 20 lamps, two would be on the positive and two on the negative, thus preserving the balance. The idea is, of course, capable of development for larger areas requiring a larger number of lamps. The fuel used is bituminous coal of a very fine quality obtained from a thin seam a few miles from Devonport.

This little scheme having been successfully launched, we shall hope in the future to place figures showing its progress before our readers. With all the disadvantages of heavy protective duties on machinery and somewhat dearer coal to contend against, it should encourage some of the smaller English towns to know that a commercial success may be made of electric lighting in such an out-of-the-way place as Tasmania.

Slight Accident at Blackpool.—One of the overhead wires on the Promenade tramway route at Blackpool collapsed on Tuesday afternoon. The front was crowded at the time, and there was an excited stampede, but the cut-off appliance worked successfully, and no harm was done beyond the dislocation of the tramway traffic for a short time.

LETTERS FROM AN OLD HAND TO A YOUNG ONE.

II.—On the Method of Training.

My Dear Young 'Un,—You have adhered to your intention of becoming an engineer, and an electrical one! I thought you would. Many ask advice: few take it. Now you want to know "the best course of training"! The problem is as difficult as the Hampton Court Maze. There are plenty of entrances: the job is to find the path that gets *there*. To make confusion worse confounded, each man has his own particular maze—no two temperaments are alike. If you want learned literature on the subject, read the discussions at the Institution of Electrical Engineers this year. There you will see how doctors disagree.

The points I should advise you to consider are, your physical constitution, your temperament, your pocket, and fortuitous circumstances. I don't know that this order is in degree of importance; you had better think them all over very carefully.

So far as I recollect, your health is normal. You did yourself credit the day we lunched at Slaters. I had to give the waitress twopence extra to save my face! Also, you are not full-back in your School Rugger team for nothing. So hard work will not hurt you. If you were a little older than fifteen, I should recommend you to go into the shops during the day and take classes in the evening. I am a trifle afraid of it at your age, however—you mustn't be an old man before you are a young one. Whether you take theory first and practice after, or *vice versâ*, is an open question—though you *must* have both. The best life to lead depends upon the liver. Above all things, you must keep fit, even if you have to go slow.

This is where your temperament comes in. If you were a very brainy man—preferring to sit down and swat rather than play cricket—I should emphatically send you into the shops right away to get some life knocked into you. The tendency for the head-work required in engineering being already strong, the aptitude for hand-work should be acquired while adaptability remains. Nothing is more pitiable than the office-man who has a horror of seeing his work through the shops; he is no more than a specialised clerk. And you should bear in mind that the ease with which technical education is now obtained, and the repugnance which exists in plunging from the College into the Shop, is turning out a glut of these paper-engineers.

But—if you will excuse my saying it as between friends—you are a trifle thick-headed as regards theory. I understand that the Binomial Theorem is rather outside your weight, and that you carelessly left the fume-chamber door open in the Practical Chemistry Class to see if sulphuretted hydrogen really was injurious to life. If you don't get some theory banged into you now, you'll never absorb it. So you had better go to a Technical College for a couple of years. And I humbly pray that patience and a saving sense of humour may be granted to your teachers. Of course, if your pater could afford it, the ideal plan would be to send you to College for, say, six months in the year, to a works as pupil for the other six, and to keep this up for three years. This would cost something, however; and I expect you would begin to grouse about losing your holidays! The ordinary college terms leave a good many gaps in the year. Why not try to get a job as odd man in a shop to fill up the time?

Fortuitous advantages may arise—you may have someone in tow who can pitchfork you into a place where experience may be gathered in armfuls. If so, haul on the tow-rope. (But don't think *I'm* on the other end of the line. I have no vacancies for beginners, and personally I think you will be a better man if you go through the rough fair and square with all the rest of them.) Don't use your influence to get salary or position. If it is a job where you are supposed to do what you *can't* do, don't touch it! There is no need to be a fool artificially—you have quite enough natural aptitude (speaking again as a friend).

Be careful not to specialise too soon. You have a lifetime before you; a long-bore gun carries further than a

Digitized by Google

short-bore. If you can spend eight years in learning with disregard for salary, so much the better for you later on. Pocket again!—the longer you can hang on to poor salary and rich experience, the better in the long run. Become a general engineer first—an electrician after. Electrical engineering can be far more easily studied from books than mechanical practice. Rub your nose into the practice while you are young; there is plenty of time later on to wear white shirts.

As a relief from engineering, study finance. An engineering firm may turn out beautiful engines, but if it doesn't pay, the shareholders will grumble. While you are in the shops, study the economic aspect of speeding-up lathes and working double gangs. If you get into a supply station, try to understand the Maximum Demand system. It is worth an engineer's while to study for some of the Institute of Bankers' exams., if he can find time.

One thing more! Don't be haughty to men of inferior education who are slogging their own way up. Engineering, above all other professions, makes a constant appeal to fact. Education and influence don't count if a man's work is not right. A fool is found out quicker in engineering than in anything else. If a man has genius, it is not safe to sneer at him even if he drops all his aitches and says "*and* et cætera." *Every* engineer carries the bâton of command in his knapsack—if he has the right knapsack.—Yours, THE OLD 'UN.

RHYMES FROM THE OFFICE.

BY PABLO.

No. 3.—The Lady Typists' Reply to the Unknown Poet.*

O poet true, O gallant, courteous knight,
Thy welcome, welcome is; thy verses sweet
Have reached our inmost hearts. Would that we might
Reach thine! Would that we could attain the height
Of poet's skill, and give thee answer meet.

Thy form eludes imagination's eye—
He's dark! He's fair! He's short! He's tall! He's thin!
He's not! Thus disagree we; vainly try
To picture (as we echo sigh to sigh)
Thy mouth, thy nose, thy lustrous eyes, thy chin.

Declare thyself, we pray thee, great unknown,
That we, who now thy highest praises sing,
May, when the bell peals forth with hideous tone,
Withhold from thee—from thee, ador'd, alone—
Our "Botheration! let the bounder ring."

TRADE NOTICES AND NOVELTIES.

Wires and Cables.

From Messrs. W. T. Glover and Co., Limited, we have received a copy of their revised catalogue of electrical wires and cables. In addition to the inclusion of the firm's well-known vulcanised rubber cables, several new features have been introduced, notably the classifying of their various types of Diatrine paper, lead-covered cables for lighting and power mains, suitable for either low or high voltages. These cables can now be subjected to Messrs. Glover's patented method of testing by hydraulic pressure, which, it will be remembered, was described in our issue for Dec. 18 last. Special attention is drawn to several types of cables recently introduced, among them being Diatrine paper, leadless cables for underground mains and mining work; bitumen insulated cables, specially suitable for solid systems; leather-sheathed cables, specially suitable for rough usage; fire-resisting, for switchboard connections for train, theatre, and ship lighting, etc. Descriptions, it may be added, are included of these cables.

Water-Distilling Plant.

The Mirrlees-Watson Company, Limited, Scotland-street, Glasgow, have sent us a copy of a pamphlet describing their "Yaryan" water-distilling apparatus. It is pointed out that in many districts the supply of water is unsuitable for use in boilers, and cannot be satisfactorily treated by any chemical system. In such cases the only remedy is distillation. Hitherto the great objection to water distillers has been the cost of fuel, but with their sextuple effect Yaryan distillers the above firm claim that the amount of fuel used has been very greatly reduced, thus rendering the distillation of water thoroughly practicable. On railways the use of sedimentary water in loco. boilers causes a very heavy expenditure in upkeep, and there are many places where a decided benefit would be obtained by the installation of an economical distilling plant. The economy of the apparatus described is stated to be such that as much as 44lb. of water have been evaporated and condensed per pound of coal used.

Electric Fans.

We note from a circular recently received that the Brush Electrical Engineering Company, Limited, Victoria Works, Belvedere-road, London, S.E., have introduced a battery fan which will run from 250 to 300 hours. These fans may therefore be introduced when there is no electric lighting supply available. The same firm are supplying a neat type of lampholder fan which can be used wherever there is an incandescent lamp fixed, by simply taking out the latter and inserting the fan.

Resistance Apparatus.

Perfecta Resistance apparatus, especially adapted for operating electric lifts, is dealt with in a price list recently issued by Messrs. Monte-Callow and Co., 6, Ludgate Broadway, London, E.C.

A Million Horse-Power.

A new publication, entitled "A Million Horse-Power," issued by the British Westinghouse Electric and Manufacturing Company, Limited, contains particulars of the more important electrical installations which have been carried out by this firm within the British Empire.

Ferranti Apparatus.

From Messrs. Ferranti Limited, Hollinwood, Lincs., we have received three publications, dealing respectively with the firm's reverse-current relay for continuous-current circuits; moving-coil instruments, 8in. round type; and shunts for moving-coil ammeters.

Fittings.

The Progress sheet issued by the General Electric Company, Limited, 71, Queen Victoria-street, London, E.C., for last month illustrates various novelties in electric light fittings which should be found exceptionally useful for showroom and window lighting. They include adjustable brackets and shelf clips. Particulars are included of "Union" steel tubing and of a new protected wall plug. A new pattern fuse and switchboard is also shown, and several new designs in pendants. We note that prices in "Champion" fuses have been reduced.

PERSONAL.

Councillor Ralph Fream (chairman of the Gloucester Tramways Committee) and Mrs. Fream were the recipients of an interesting presentation at the Guildhall, Gloucester, last week. The presentation to Mr. Fream took the form of a handsome replica of one of Gloucester's new electric cars, made in silver and polished oak, designed as a smoker's cabinet. The elegant little model, which is 17in. or 18in. in length and about 12in. in height, bore the following inscription: "Presented to Councillor Ralph Fream by the Mayor, Sheriff, Aldermen, and Councillors of Gloucester as a slight recognition of the great services rendered as chairman of the Gloucester Electric Tramways during their construction and opening, May, 1904." The present to Mrs. Fream consisted of a family silver five o'clock tea service and a gold bracelet.

The Aston (Birmingham) Town Council have decided to retain the services of Mr. R. Green, of Pritchard, Green, and Co., Birmingham, as consulting engineer upon the terms of the existing agreement in relation to the reconstruction of the tramways about to be purchased from the City of Birmingham Tramways Company, Limited.

Mr. John McGown, St. Ronans, has been appointed manager of the Bo'ness electric supply works, under the National Electric Construction Company, of London.

The Gloucester City Council have awarded Mr. R. Read, the city surveyor, an honorarium of £500 for his services in connection with the conversion of the tramways to electric traction. A sum of £200 was voted to his assistants.

The Erith Urban District Council have appointed Mr. G. W. Blake clerk of works in respect of the alterations and additions to be made to the electric lighting station.

APPOINTMENTS VACANT.

Fitter Driver, wages 36s. per week, Switchboard Attendant, wages 25s. per week, Stoke-upon-Trent Electricity Committee. Applications by Aug. 13. See advertisement.

Lecturer in Electrical Engineering in the University of Sydney, N.S.W. Salary, £500 per annum. Applications by Sept. 10. See advertisement.

* The fair sex had been recently introduced into the typing department, and the office poet had written (anonymously) some effusive verses of welcome. The ladies either had not the gift of poesy or were too shy to make use of it, and the present writer, ever the willing servant of beauty, concocted the above for the occasion.

Bound Volumes of "THE ELECTRICAL ENGINEER," *containing half-year's copies, bound in Dark-Blue Cloth, Gold Lettered, price 8s. 6d. New Volume, January to June, 1904, now ready.*

WIRELESS TELEGRAPHY.

The policy of the Government with regard to wireless telegraphy is embodied in a Bill to be passed—organised opposition permitting—during the present session. The first paragraph in a memorandum attached to the Bill says, "The object of this Bill is to give the Government control over wireless telegraphy, in order to preclude its improper use in time of war or in any other national emergency, and to regulate the working of different stations in such a manner as to secure the greatest efficiency of communication between all stations." We agree with the policy. We have read the Bill, and it is not worth the paper it is printed upon. The Bill, if passed as drafted, will be utterly useless to effect the object desired, and its only result will be to increase the number of curses hurled against Government departments. Clause 1 of the Bill reads: "A person shall not establish any wireless telegraph station, or instal or work any apparatus for wireless telegraphy, in any place or on board any British ship except under and in accordance with a license granted in that behalf by the Postmaster-General, with the consent of the Admiralty, the Army Council, and the Board of Trade." Imagine for a moment that a ship in the Black Sea has installed upon it a wireless telegraph under license of the Postmaster-General, and there is a station at Odessa, to which port the ship is bound, also that the Russian authorities take into their heads to issue licenses and regulations diametrically opposed to those of the Postmaster-General; or, further, assume that no nation with ports permits wireless telegraphy to be used in accord with the regulations in the license. What then? Is a ship in a fog going to trouble about a lot of silly restrictions, or to care one iota what a license says? It will, of course, work its telegraph to its own salvation. In time of war the Government already possesses powers amply sufficient to close every station upon shores under its control. It can with its existing powers enter into occupation and control, and, therefore, need not fear the transmission of messages that would be a source of danger. So far as war is concerned, the Bill gives no powers over and above what already exist, in that any civilised Government can and does take whatever action it pleases relative to the necessities of the case. Law takes a back seat during war. The necessity of national existence then rides rough-shod over legal forms. But while the great point made by this Bill and the memoranda accompanying it is strategical necessities, one very real question is, What effect will it have upon social and commercial relations? War can and will take care of itself. A clause in one memorandum reads: "One of the great difficulties to contend with in wireless telegraphy is interference as between neighbouring stations, and this must be met with by limitation of the number of stations and careful selection of sites." Who is to select the sites? The Government with a view to strategical requirements, or the licensee with a view to commercial wants? Similarly, who is to decide as to the limitations, and what is to be the prevailing factor? The two classes of requirements are irreconcileable. If the Government wants strategy, let it erect and equip its stations; if it wants commerce, the Government has neither the knowledge nor the experience to determine what is wanted and why it is wanted. Practically, the granting of licenses will mean the creation of another monopoly, for once in possession it will be impossible for a second company, even if it has an improvement to exploit, to come along and obtain a license when limitation is strictly adhered to. Surely the history of telephony ought to make the Government pause before creating

Digitized by Google

another monopoly. Progress is not so rapid as to warrant the cancellation of A's license because B comes along with a slight improvement—and improvements come gradually. Altogether, the Bill as it stands will give a monopoly to the company getting its license first, and those who come after will be nowhere unless the selection of sites brings about the bankruptcy of the first-comers. Can we suggest an alternative scheme? Frankly, no. Except (*a*) let the Government do the work itself, or (*b*) let commerce fight its own battle without restriction, when sooner or later natural selection will provide for the survival of the fittest.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

TELEPHONY AT GLASGOW.

SIR,—Perhaps you will allow one of the "academical arguers" to say a word on this subject. My argument at Glasgow in 1897 was that the proposed scheme provided too little plant in proportion to the estimated number of working subscribers. The Table A, printed on your p. 152, amply proves the correctness of that argument. The table shows that there are twice the number of completed instruments that the estimate provided for, and it shows that to serve twice the estimated number of instruments, there have been required nearly four times the estimated length of wire, nearly seven times the estimated amount of trenching, nearly five times the estimated length of duct, and nearly seven times the estimated length of cable. The effect of this miscalculation on the finances of the concern is that the ratio of gross revenue to capital expenditure is only just over half what the estimate showed would be attained. In other words, for a given result in gross revenue the Glasgow Corporation telephone department have spent nearly twice the amount of capital that was estimated to be required.

It strikes me as a misuse of terms to describe these results as having "successfully proved in the concrete what was academically argued to be impossible." They show, on the contrary, that there has been a miscalculation of nearly 100 per cent. Nothing academical about that!—Yours, etc.,

HERBERT LAWS WEBB.

35, Old Queen-street, S.W., July 30, 1904.

[I am sorry to disagree with Mr. Webb, but venture to say that the Glasgow figures prove nothing of his view. The old adage, "A man convinced against his will, is of the same opinion still," applies in this case, and Mr. Webb will not, perhaps cannot, see that there is absolutely no connection between estimates for one thing and costs for another. Mr. Webb claims to be a man of experience. What really is his experience in comparison with that of Mr. A. R. Bennett's? Ironically he terms himself an "academical arguer, and he hits the goal by accident, not by intention. Here is a simple problem. Given a central telephone exchange at A, any number of instruments over a circular area with radius x, with capital cost per instrument y. Now double or treble that number of subscribers over area radius $2x$. Will the cost be $2y$ or $3y$, or if not, why not; or will it be any multiple of y, or can it be connected with y in any way; again, if not, why not? Is it not a fundamental fact that the controlling factor of length of wire, trenching, and ducts is area, not instruments?—THE WRITER ON TELEPHONY IN THE *E. E.*]

REGENERATIVE TRAMWAY MOTORS.

SIR,—I have been very much interested in reading your description of the demonstration at Gravesend on Wednesday last. Your observations of the energy expended and returned to the line are exactly such as the tramway world has been waiting for, and will undoubtedly convince the most sceptical of your readers as to the reality of the regenerative effect. I regret to find that some of the information which I supplied was not so clear as it ought to have been on the subject of the size of motor required for economical and satisfactory re-generation.

The demi-car with two 28-h.p. motors is obviously over-motored, but I cannot find any cheaper or lighter motors on the market. One motor would do the work easily, but if only one axle were driven, the adhesion on the grades would be insufficient. At Devonport, which has worse gradients, and more of them, the motors are of the same size—viz., 28 h.p.—and the cars are of the same size as the large cars at Gravesend—*i.e.*, about nine tons. The Devonport motors since their conversion have been in regular service eight months, and are quite as satisfactory as they were previously. It is obvious, however, to any tramway engineer that they are rather too small for the line, which is one of the most severe in the country. Albeit these cars are daily overloaded, and have carried over 100 passengers per car.

With regard to my note to the effect that the demi-car takes less than half the energy consumed by the ordinary car, this was intended to mean energy *per car mile*, not per ton-mile. The actual figures are ·4, as against ·9, which proves my claim that the demi-car not only saves half the labour, but also half the energy as compared with an ordinary full-size series-parallel car. Therefore, when substituted for an ordinary car on a lean line, it will run at half the cost per mile, and thereby transform a loss into a profit. These lean lines exist in great numbers, to the detriment of the financial results.

I have approached these subjects from the points of view of the tramway director and shareholder. The object of the invention is to increase the value of tramway property by raising dividends and by reducing risk of accident. That they will have these effects no one who witnessed the demonstration at Gravesend can doubt.—Yours, etc.,

JOHN RAWORTH.

2, Queen Anne's-gate, S.W., Aug. 1, 1904.

P.S.—A very simple calculation shows that the saving to be effected is equal to something in excess of £450,000 per annum in Great Britain alone.

ARTIFICIAL LOADS.

SIR,—*Re* tank for artificial loads for the dissipation of electric energy which appears in the *Electrical Engineer*, July 22, 1904, there is nothing particularly original in the method of placing one iron tank inside another in order to build up an artificial load suitable for dynamo testing, as many engineering works and central stations are using at the present time similar arrangements for the above purposes. Neither is it always advisable to earth the outer tank, especially in an engineering works where large foundation plates are used for bolting down machines which are about to be tested, because by so doing you practically reduce the insulation resistance of the machine down to one-half, which may cause trouble.

I should like to ask the writer how long he proposes to run a machine under test, because he mentions the fact that he does not like the use of canal water for the above purposes, owing to it changing its specific resistance considerably during the period from winter to summer. Surely he would not run a machine for six months in order to test its efficiency or general behaviour of same. Usually from 10 to 12 hours' run will satisfy any reasonable engineer, during which time he will find that the physical properties or the conductivity of the canal water has not altered much, if any, certainly not enough to interfere with the test. With regard to the use of chemicals, such as sulphuric acid, salts, and common soda, I beg to say that these should never be used upon any account where a very steady constant load test is required. If the tank is suitably designed, with ample electrode surface (both anode and kathode), together with some convenient arrangement for varying the distance between these electrodes, also with a large supply of cold water (either canal, river, town, or even condensed water) for circulating through the tank, then, with a reasonable small tank, there is not the slightest reason why any size of machine up to at least 1,000 kw. could not be run under full load without the use of any chemicals whatever.

Digitized by Google

Some years ago I, for the first time, made it known to the engineering community (by giving analysis and specific resistances of various waters) that it was quite unnecessary to use chemicals of any kind for any waters when testing. Again, 2½ years ago, a discussion took place between myself and another well-known engineering gentleman upon the question of testing tanks, chemicals, various waters—in fact, on similar lines to this, when I gave a few particulars and dimensions of tank I had been in the habit of using. See *Electrical Review* for Jan. 17 and 31 and Feb. 7, 14, and 21, 1902.—Yours, etc., YRREB.

THE DIESEL OIL-ENGINE.

SIR,—In your issue of the 29th ult., while mentioning that at a recent consumption trial of a Diesel oil-engine of 160 b.h.p. the extremely low consumption of 0·37lb. of crude petroleum per brake horse-power was obtained, you state that "*other fuel* comes out as low as $\frac{1}{12}$d. per brake horse-power." There is apparently a slight misunderstanding here, inasmuch as it is the figure above mentioned—viz., 0·37lb. crude petroleum—which, on the basis of 42s. per ton, shows a fuel consumption cost of $\frac{1}{12}$d. per brake horse-power.—Yours, etc.,

DIESEL ENGINE COMPANY, LIMITED.

[N.B.—We are afraid that the word "other" is a stenographic error for "or the." The sentence was dictated to read, "Or the fuel comes out as low as $\frac{1}{12}$d. per brake horse-power hour."—ED. *E. E.*]

RUBBER CULTIVATION IN PARA.

A more optimistic view of the future of rubber cultivation than was given in the recent report by U.S. Consul Edward M. Conley, at Mexico City, Mexico, is held by U.S. Consul Louis H. Aymé, at Para, Brazil. In a recent report Mr. Aymé describes a rubber plantation owned by a Mr. Martins in a suburb of Para. Several years ago this gentleman cleared a property of five acres of sandy ground. He planted here a number of seeds of the Hevea brasiliensis, which have grown and flourished, chiefly on the higher ground. The success promised from these experiments encouraged Mr. Martins to plant several thousand seeds three years ago. This spring, for the first time, he tapped 40 of the best and largest trees, and from them secured a good output of rubber. Mr. Martins, when he planted the rubber trees, also planted a number of inaja palms, which furnish the nuts used in smoking the rubber. There are on this plantation to-day several hundred trees that are beginning to yield latex, and there are between two and three thousand young trees from 2ft. to 20ft. high. The usual forest "run" is about two miles long, and it is a good run that has 100 trees; but here, in a space of five acres, it is estimated there will be in 10 years at least 1,000 full-bearing rubber trees, which will produce more and better rubber than the tree on the forest runs, for it will be gathered more quickly and in a cleaner manner, and with greater care of the tree in tapping. The consul believes that there is no longer any doubt of the success of this experiment; and this would seem all the more important, as the Hevea brasiliensis trees of the great Amazon valley are being exhausted, and it is doubtful whether nature can replace them with sufficient rapidity to keep pace with the present demand for rubber. A possible reason for the unsuccessful attempts to raise these trees elsewhere is suggested. It has been found that the seeds of the tree germinate very soon after falling, but they lose the power of germinating quickly; hence it is very difficult to transport them in good condition. Consul Aymé thinks that there is an opportunity here for profitable investment of large capital, and the establishment of extensive plantations. Much study of conditions would be necessary, and it would probably take 10 years before the plantation would be yielding profitably, though, under favourable conditions, trees five years old would yield. To engage in this work a capital of not less than £10,000 would be required—preferably much more than this. We take the above from the *Electrical Review* of New York.

WIRELESS TELEGRAPHY.

BY R. G BLAINE, M.E., A.M.I.C.E., ETC.

(Continued from page 80.)

SPANISH EXPERIMENTS.

The Cervera System.—Spain has also recently added her quota to successful research in this branch of science and invention, and we find the system of Señor Cervera adopted and giving good results. In some respects this system differs from those already described, especially in the construction of the coherer. The transmitter has the usual vertical aerial with earthed connection, and the usual induction coil with spark gap, a condenser being inserted in each arm of the oscillator near the spark gap. The same antenna is used both for receiving and transmitting, there being a changing switch which cuts out the condensers and spark gap when receiving. The antenna is earthed through the primary of a small transformer, as before, the secondary of this transformer being divided by cutting out one spiral of winding at the centre of the coil and inserting a condenser between the terminals thus formed, after the manner of the Marconi "jigger." The terminals of the condenser are in turn connected to the terminals of the coherer, which consists of two small *ivory* discs, which may be adjusted by micrometer screws, having between them the conductors, which are in this case plugs of soft annealed iron with the usual powdered metal between them. The Cervera receiving apparatus has *four* separate circuits, which in turn fulfil the following functions: (1) operating the Morse machine, (2) making and breaking the coherer and relay circuit, (3) actuating the tapper, (4) interrupting the circuit of an electromagnet the function of which is to alter the sensibility of the coherer. The whole receiver, with its various circuits, is somewhat complicated, but is said to work well. The system has been successfully tried at various stations, and also across the Straits of Gibraltar, a distance of 34 km. (21¼ miles).

AMERICAN SYSTEMS.

The De Forest System.—This system is due to Dr. Lee De Forest and Prof. C. E. Freeman, of the United States. The

DR. LEE DE FOREST.

transmitter is not of the usual cell and Ruhmkorff coil type, but is much more powerful. A 110-volt continuous current from a dynamo or accumulators is transformed by a rotary transformer into an alternate current at a pressure of about 500 volts, which is further increased to 25,000 volts in an oil transformer, 3 (Fig. 70A). This high-pressure but low-frequency alternating current is used for charging a series of condensers, represented by 7, 8 in the illustration. The discharge of these condensers through the spark gap, 6, gives rise to the ether waves necessary for the transmission of the message. The aerial, 4, is connected to one spark ball or disc and the other to earth. The pressure being high, great disturbance of the ether takes place, hence long distances may be traversed and yet the effect be sufficiently powerful to give a readable message.

Digitized by Google

A key, 2, working in oil is used to make and break the circuit of the transmitter. The receiver circuit is shown diagrammatically at B (lower figure). Its circuit includes the aerial, which is connected to the primary of a small transformer, the secondary of which is in the local circuit, the latter including the responders, 1′ 1″, inductance coils, 2′ 2″, resistance, 3′ (about 5,000 ohms), the condenser, 5′, and the telephone receiver, 6′. There are keys, 9′ 9″, for relieving the responders. There is also a battery, 4′, the current from which flows through the telephone all the time the apparatus is in use.

The responder deserves special notice. It is of the anti-coherer type, as its resistance is *increased* under the influence of impinging ether waves, and thus the current flowing normally through the circuit of the responder is interrupted. The responder is really a little electrolytic cell; the electrodes being of soft metal are placed in a paste composed of metallic particles, and a liquid which can be electrolysed by the current. The current flowing normally detaches minute particles of metal, causing them to pass from one electrode to the other, the normal resistance of the cell being small. When the ether waves set up by the transmitter reach the responder, hydrogen bubbles are generated at the kathode, and form a cushion which increases the resistance of the cell, momentarily interrupting the current, causing the telephone diaphragm to be momentarily released

B, Receiver; 1′, 1″, Responders; 2′, 2″, Choke Coils; 3′, Resistance 5,000 ohms; 4′, Battery; 5′, Condenser; 6′, Telephone Receiver; 7′, Antenna; 8′, Ground; 9′, 9″, Shunt Switches.—(From *The Engineering Magazine.*)

from the pull of its magnets, and a sharp click is heard in it. A series of impulses sent at proper intervals give rise to a series of clicks arranged to convey a message in the Morse code.

The system has been very successful. On Dec. 11, 1902, the Coney Island station of this company caught messages from the "Philadelphia" when the latter was 100 miles away, the vessel having Marconi apparatus. No tuning device is used at Coney Island. The "Philadelphia" was overheard calling up the Babylon station, and later the Sagaponack station. The aerials at Coney Island are simple two-stranded copper wires 210ft. high. In the dock at New York, with miles of metal warehouses intervening, conversation was carried on with the "Deutschland," which is equipped with apparatus of the Arco-Slaby system, but it was found necessary to replace the coherer of that system by the responder of the De Forest system. Messages have been received by a De Forest pocket receiver measuring 5in. by 4in. by 3in. from a distance of 100 miles. The equipment of trains has been taken in hand, and we understand that the "Twentieth Century Limited" express on the New York Central Railroad is to be fitted with the apparatus of this company to communicate with stations near the track 100 miles or so apart. The system has now, it is said, been adopted, after severe tests, by the United States army and navy.

A photograph of a complete De Forest transmitter set is shown in Fig. 71, kindly sent by Dr. De Forest—the key to the right, variable inductance or resistance in the centre, the oil transformer and spark apparatus to the left. American papers tell us that before the possibility of Transatlantic wireless telegraphy was demonstrated, this company had completed plans for establishing stations by which not only America, but the Pacific, could be spanned. One of the latter is to be at the southern end of California,

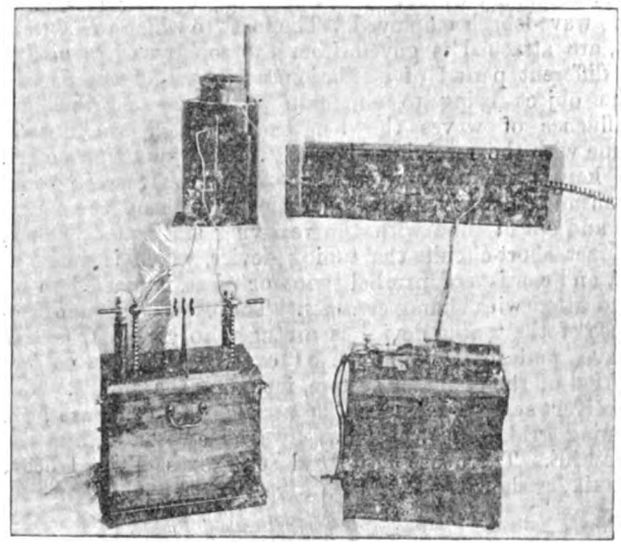

FIG. 71.—The De Forest System.

another (a relay station) at the north end of Hawaii, one near Manila, and one at Hong Kong. The towers at Manila and Honolulu are to be 250ft. high. They will support three screens of vertical wires at each station. The distance between Manila and Hawaii will be 3,500 miles, that between Hawaii and California 2,200 miles. Stations at Cape Hatteras, Key West, Havana, etc., are now being equipped or are in working order. Should Dr. De Forest succeed in negotiating these long distances, he may claim a place in the very front rank in regard to wireless invention and enterprise at the present time. Like Marconi, he is young—only 30. He is graduate (Ph.D.) of Yale.

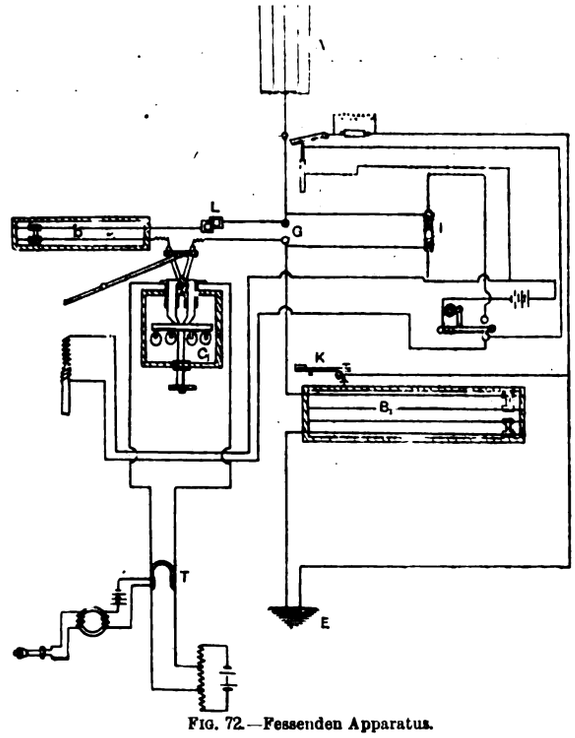

FIG. 72.—Fessenden Apparatus.

The Fessenden System.—This system has been successfully developed by Prof. Reginald A. Fessenden, of the United States Weather Bureau. Prof. Fessenden claims to use, not free Hertz waves, but "semi-free" waves. In his patent specification the professor says: "In the Lodge waves the electrical energy is a maximum when the mag-

Digitized by Google

netic energy is a minimum, and all the energy not absorbed by resistance is recoverable; with the form investigated by me the electrical energy is a maximum at the same time as the magnetic, and none of the energy radiated is recoverable except by deflection." The "aerial," A (Fig. 72), may have several wires in parallel, and there is usually a secondary conductor joined on to these, which may be carried in a horizontal direction over buildings, etc., being earthed at each end. The length of each arm of this secondary conductor is approximately one-quarter of the wave-length employed. The mast to which the aerials, A, are attached is guyed from the top by wires having a different period of oscillation from that of the aerials, the object being to eliminate as far as possible the influence of waves the lengths of which are not in tune with the receiving apparatus. The induction coil, I, is kept continually in action when messages are being transmitted, a key, K, being employed to throw the aerials in and out of tune with the receiving station. The key, in fact, short-circuits the tuning device, which is shown at B', and consists of parallel strips or wires immersed in oil and fitted with sliding contacts. The capacity and inductance of the tuning device is arranged to give a true sine wave, and to agree in period exactly with the natural period of the oscillator system, including the aerials. The receiver system includes the aerials, the condenser, L, tuning grid, *b*, electromagnetic wave detector, C, and the earth, E. There are also head telephones, T, and other details, as shown in the illustration.

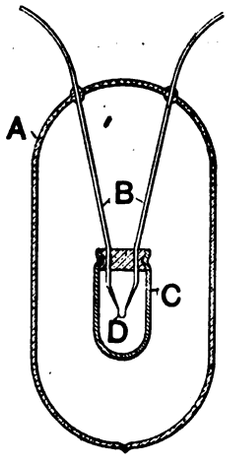

FIG. 73.—Fessenden Electromagnetic Receiver.

The electromagnetic detector or responder, C, is of special interest, and is shown in section in Fig. 73. It consists of a short loop of fine silver wire, D, ·002in. in diameter, with a core of platinum wire ·00006in. in diameter, and is fastened to the terminal wires, B, which are sealed into the glass bulb, A. The tip of the silver loop is dissolved or eaten away by nitric acid, leaving the platinum wire exposed, and to decrease the loss due to radiation, the loop is enclosed in the silver shell, C. The action of the receiver is practically that of the bolometer, and has already been referred to. The radiating or absorbing surface is here, however, very small compared with the mass. The heat capacity is therefore small, and a very small—in fact, nearly infinitesimal—quantity of heat suffices to raise, and sufficiently raise, the temperature of the wire. The glass bulb is exhausted to increase the sensitiveness of the receiver. C (Fig. 72) is a stand for a number of these detectors, it being considered best to have several, so that another can be immediately switched into circuit should the one in use fail.

Both the De Forest and Fessenden systems are said to admit of a high rate of word transmission telephones being used. They have also been subjected to severe tests during the United States naval manœuvres, and at other times, though on the occasion of the manœuvres the distances were not great. One very important phase of the Fessenden system is the possibility of syntony by the alteration of the frequency of the diaphragm in the receiving telephone. Prof. Fessenden found that a diaphragm clamped all round its circumference had a natural period of vibration, which could readily be varied, say, by altering the radius of the clamping ring. In this way the telephone could be made to respond to ether oscillations of its own frequency better than any other, and that frequency could be varied by the simple device referred to. Thus tuning or syntony, and to a certain extent secrecy of transmission, may be secured.

The Guarini Repeater and Guarini Wireless Fire-Alarm.

With a good and economical system, it may be that for land transmission, at any rate, great power and expensive stations are unnecessary; the use of an automatic repeater like that of M. Emile Guarini, of Brussels, may yet solve the problem of wireless telegraphic intercommunication. The object of the apparatus is to receive messages from a station and repeat or retelegraph them on automatically to a further station or stations. The circuits of the apparatus are shown diagrammatically in Fig. 74, where 1 is the aerial, 2 conductor connecting aerial to negative pole of relay 4, 5 conductor (placed in metallic tube) joining armature 6 of relay 4 to primary 7 of little transformer 8, 13 is a condenser, 14 the coherer, 24 tapper of same, 15 induct-

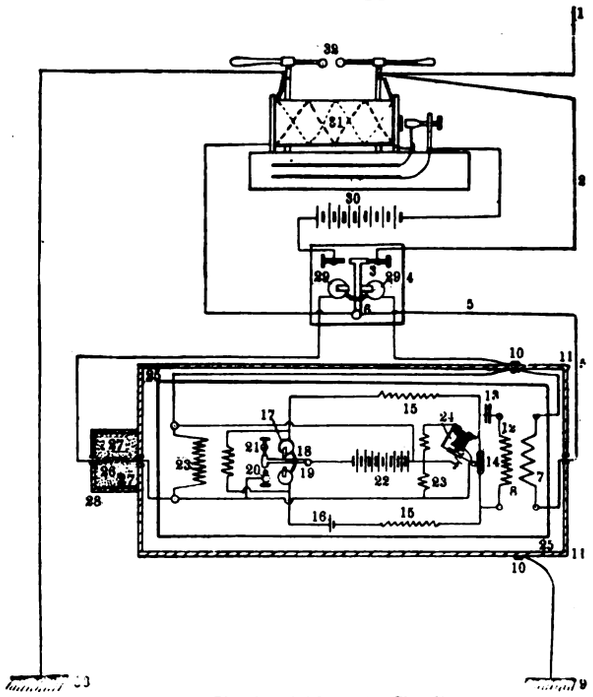

FIG. 74.—Guarini Repeater Circuits.

ance coils, 16 a cell, 17 coils of the relay 18, 20 and 21 terminals of the same, 22 source of electrical energy, 23 shunts, 25 the table on which the apparatus rests, 26 inductance, 28 a metallic box joined to the other metallic envelope 11, 29 arc coils of relay 4, 30 source of electrical energy, 31 induction coil, 32 the oscillator or spark gap, 33 the earth or a capacity. In the case where it is necessary to register the signals repeated, relay 4 works a Morse printer.

Action of the Apparatus.—Suppose that between two stations (transmitter and receiver) there is a single repeater, the Morse dot and dash code being used. At the transmitting station an electromagnetic wave of short duration is produced, say, by an oscillator like 32. This wave projected into space is too feeble to reach the receiving station, but is strong enough to affect the aerial, 1; is collected by 1, but is not able to traverse the secondary of coil, 31, and reach the earth (or capacity), 33, on account of the great impedance of the circuit. The wave, therefore, traverses the conductor, 2, the terminal, 3, of the relay, 4, the conductor, 5, of the primary, 7, of the transformer, 8, and reaches the ground (or capacity) at 9. On account of induction in the secondary, 12, of the transformer, 8, the coherer, 14, is impressed so well (the self-induction coils, 15, hindering the waves from following the circuit of the cell, 16) that the coils, 17, of the relay, 18, are energised, the armature, 19, of the relay is attracted, and leaving the position of rest, 21, applies itself against the buffer, 20; the current of the cell, 22, acting on the tapper, 24, the latter decoheres the coherer, 14, the same time that a current circulates round the coils, 29, of the

Digitized by Google

relay, 4. The armature, 6, of the relay, 4, is attracted. It leaves its position of rest, 3, and places itself against the working buffer of 4 at the same time that the armature, 6, closes the circuit of the source of energy, 30, of the primary of the coil, 31, and a spark leaves the oscillator. It will be noticed that at this instant an interruption has been caused between the terminal, 3, and the conductor, 2, going to the receiving antenna. Thus the relay, 4, sends on the signal received, and it may also print it through the agency of a Morse printer. The lower part of the apparatus, being enclosed in a metallic box, is not affected by the spark of the oscillator, hence the apparatus is again ready to receive a fresh signal. A number of dots sent in quick succession form a dash, and so on, as usual by the Morse code. There may be a number of repeaters between the extreme transmitting station and the final receiving station, but the action is the same: No. 1 repeater repeats the short and long signals to No. 2, No. 2 repeats them to No. 3, and so on, till they finally are received at the extreme station. There is no danger that the signals of one repeater may react on another, for when a signal is reproduced to No. 2, the circuit of the receiving antennæ, 1, of repeater No. 1 is interrupted. It is only when the signal arrives at repeater No. 3—*i.e.*, out of reach of No. 1—that receiver No. 1 becomes capable of receiving and retransmitting a new signal from the extreme transmitting station. In practice, all this takes place as rapidly as if there were direct communication, for by diminishing the distance of transmission, the capacity of the station, the size of the induction coils, and hence the time constant, are all reduced.

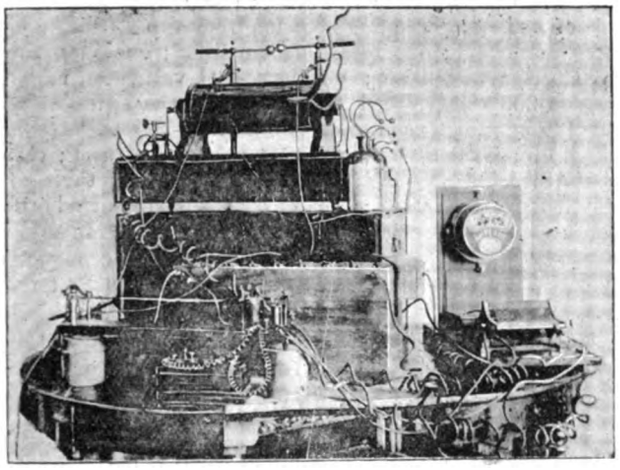

FIG. 75.

An illustration of the apparatus is shown in Fig. 75. Other forms of the apparatus which have been employed by M. Guarini need not be further referred to here. The apparatus has been thoroughly tried. Experiments were made between Brussels and Antwerp, with a repeater at Malines, in order to test the value of the repeater over considerable distances. The experiments proved very successful. An observer at Malines—Licutenant Fernand Poncelet, of the Belgian Artillery—had simply to note, watch in hand, the time of the passing of certain signals, and the printed records of these signals made by the repeater were, after the experiment was finished, compared with the records received direct from Brussels at the extreme receiving station at Antwerp, as well as with those sent out from Brussels. The printed records were found to be absolutely identical. All the messages sent out from Brussels were not received at Antwerp, but the latter station received correctly every one of the messages received at Malines and passed on by the repeater. The absolute fidelity of the repeater was thus proved conclusively.

M. Guarini has also made some experiments in the direction of securing the radiation of electric waves in any required direction only. Evidently this, if successful, will greatly aid other efforts to secure secrecy in transmission. M. Guarini attempted to do this by limiting the issuing waves to a narrow band directed towards the receiver he wished to communicate with. To effect this he carefully covered his central antenna or core with insulation, and enclosed it in a metallic sheath cylindric in form, with a vertical slit in one side, the slit facing in the direction in which the distant receiver was situated. The central core was connected to one of the oscillator or spark knobs, the outer sheath being connected to earth. It was supposed that by this arrangement only that portion of the core opposite the slit would send out Hertzian radiations into space. Considerable success attended this effort, we believe, especially when the screen was connected to earth, but it has been tried mainly for short distances. The matter, however, is of great importance, and is worthy

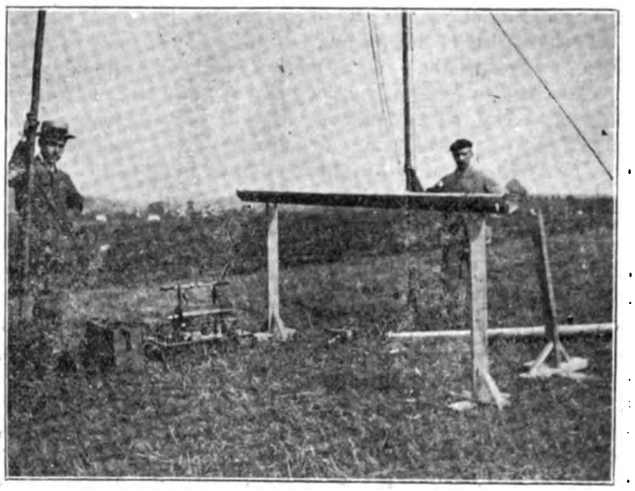

FIG. 76.—Experiments of M. Guarini on "Limitations de l'espace" (with Metal Envelopes.)

of further research. Fig. 76 shows some of M. Guarini's experiments in progress.

(To be continued.)

ILFORD ELECTRICITY ACCOUNTS.

The accounts of the Ilford electricity department for the year ended March 31, 1904, show a total expenditure on capital account to that date of £106,238. We give herewith abstracts of the revenue account and general balance-sheet.

Dr.	REVENUE ACCOUNT.	£	s.	d.
Generation of electricity		6,555	4	11
Distribution of electricity		415	12	4
Attending and repairs to public lamps		1,170	0	1

POWER DISTRIBUTION IN THE PINXTON COLLIERIES.

A most complete and up-to-date system of colliery electric power in the Midland Counties has recently been installed at the Pinxton Collieries, near Alfreton, Derbyshire. Labour saving by electric power is the essence of the system, which has been largely designed and carried out under the supervision of Mr. Benjamin Madew, the general manager of the nine collieries owned by the Pinxton Coal Company, Limited. The Pinxton pits are really amongst the oldest in the country, having been worked since the eighteenth century, and possibly longer in some form or other. Mr. Madew is this year the president of the Midland branch of the National Association of Colliery Managers, and to signalise his year of office he invited the members to hold their annual meeting at Pinxton on Saturday last, and to inspect the elaborate system of electric power now in full working order. The company assembled at noon at the colliery offices, where the visitors were received by the president. The company were conducted round the new workshops and electric station, and saw the various machinery in full operation. Everything is done by machinery, from the stitching of the horses' harness to the hammering of iron in the blacksmiths' shops, and, of course, the utilisation of electric power below ground is as elaborate as it is upon the surface. The following are the principal officials: Mr. J. Clarke, mechanical engineer; Mr. A. Lee, assistant engineer; Mr. J. F. Milnes, electrical engineer; Mr. J. Hartshorne, manager No. 3 pit; Mr. J. Jones, No. 2; Mr. Owen Houfton, No. 1; Mr. Job Smith, Nos. 7 and 9; and Mr. T. Savage, No. 8.

The following is a description of the electric high-tension three-phase power plant and workshops. The plant consists of two Lancashire boilers, each 30ft. by 8ft. diameter, 160lb. per square inch pressure; one horizontal cross compound condensing engine of 250 i.h.p.; one three-phase generator of 150 kw. capacity, rope-driven from the above engine; one Willans patent general valve triple-compound engine of 250 i.h.p. direct coupled to a three-phase alternator of 150 kw. capacity; one main and two sub-station switchboards, with switches and instruments; the necessary high and low tension cables; nine 5-h.p. motors for driving shop tools, mortar mill, etc.; 10 3-h.p. motors for similar purposes; four 1-h p. motors for driving leather-stitching and lamp-cleaning machines; four main and tail rope haulage gears with 3ft. drums; one endless rope haulage gear with 4ft. pulley; five 20-h.p. motors for driving same; two sets of three-throw pumps, each set driven by 5-h.p. motor; 10 three-core three-phase transformers, with the necessary switchgear and fuses—current for both motors and lighting is taken from the low-tension side of these transformers.

Boilers.—The boilers are two in number, and supply steam at a working pressure of 160lb. per square inch for the power plant alone. They are 30ft. long by 8ft. diameter.

Engines.—One engine is of the horizontal compound condensing type, the condenser air-pump ram being driven from the low-pressure piston tail rod. Diameter of high-pressure cylinder, 14in.; diameter of low-pressure cylinder, 25in.; length of stroke, 30in.; revolutions per minute, 107; steam pressure per square inch, 160lb.; indicated horse-power, 250. This engine is fitted with Hartnell's governor, which actuates the expansion valves of both cylinders simultaneously. A flywheel, 14ft. diameter and grooved for 10 1¼in. ropes, is fitted between the high and low pressure cylinders. In the case of the combined set the engines are of Willans's patent central-valve triple-compound type, fitted with automatic expansion gear. Number of cylinders, 6; diameter of each high-pressure cylinder, 12in.; diameter of each low-pressure cylinder, 17in.; length of stroke, 8; revolutions per minute, 375; steam pressure per square inch, 160lb.; indicated horse-power, 250.

Three-Phase Generators.—The generators are of the revolving-field type, "star" connected. The high-tension conductors are stationary and embedded in slots in the iron core. Total output in kilovolt-amperes, each, 150; current in amperes per phase, 80; volts between phases (virtual), 1,100; cycles per second, 50; revolutions per minute, rope driven 425, direct driven 375. The main shaft of the rope-driven generator runs in three bearings and carries a pulley grooved to receive the ropes from the engine flywheel and also a rope pulley for driving the exciter. Sliding bed-plates are provided so that the slack of the ropes may be taken up whilst running. The direct-driven generator is coupled to the Willans engine, and its shaft runs in a white-metal bearing fitted with ring lubricators, which render the shaft self-lubricating.

Exciters.—In one case the exciter is driven by ropes from the main shaft of the generator, and furnishes a continuous current of 30 amperes at 150 volts. In the case of the direct-coupled set, the exciter is carried on a continuation of the main shaft, and generates a current of 40 amperes at 100 volts.

Main Switchboard.—The main switchboard consists of white marble slabs supported by a framework of channel iron and placed on a gallery overlooking the engine-room, and contains the following: one synchronising panel with the following apparatus: one recording voltmeter reading to 1,200 volts; one measuring transformer with fuses; one synchronising voltmeter with lamps; two direct-current ammeters; two single-pole switches and fuses; one rotary synchroniser; two main regulating rheostats with multiple contacts and hand-wheels; one shunt regulating rheostat with multiple contacts and hand-wheels; one shunt regulating rheostat (multiple contact); two generator panels to control the circuits of two 150-kw. three-phase generators. Each panel contains the following: one high-tension three-pole oil switch; three high-tension removable tube fuses; three ammeters; one recording ammeter; one measuring transformer with fuses; one large-dial voltmeter, reading up to 1,200 volts, placed at the top of the switchboard; four feeder panels, each to carry one three-pole high-tension oil switch; three high-tension removable tube fuses; three ammeters; four feeder panels, each to carry one three-pole high-tension oil switch; four high-tension removable tube fuses; three ammeters. All the high-tension fuses are placed below their respective panels, and are mounted upon marble slabs and are protected in front by a strong steel wire grid.

Mains (High-Tension).—From the main switchboard the current is taken to No. 2 and No. 3 sub-stations by a three-core, paper-insulated, lead-covered, and steel-armoured cable, placed direct in the ground, the sectional area of each core being ·062 square inch. From the main switchboard down No. 6 shaft the cable is carried in strong pitch-pine casing specially made at the colliery workshops. The cable is a tight fit in the groove, which makes it self-supporting for the entire length. The covers are nailed on. The lighting at the pit bottom is taken from a 2-kw. single-phase transformer, which reduces the pressure from 1,100 volts to 230 volts in one phase only. This cable then leads to the motors at work on the various planes. At each point the cable is connected to a 45-kw. three-phase transformer fixed in the haulage room, which reduces the pressure from 1,100 volts to 520 volts. The low-tension side is fitted with a main triple-pole switch and four single-pole fuses. From the fuses the current is taken direct to the starting and reversing controller.

Hauling Gears and Motors.—The four main and tail hauling gears are of the following dimensions: diameter of drums, 3ft.; width of drums, 1½ft.; speed of rope, eight miles per hour. Each haulage drum is fitted with a friction brake, claw clutch, and the necessary gear for operating the same. The drums, spur gear, countershaft, and motor are mounted on steel girder bed-plates. The endless rope gear has a pulley 3ft. diameter. In each case the motor and hauling gear is fixed on the same bed-plate and drives the countershaft by means of a machine-cut spur wheel fixed on the countershaft, and a raw-hide pinion on the motor shaft. The motors are each of 20 effective horse-power, of the three-phase type at 520 volts, 960 revolutions per minute, but the motors are capable of working up to 50 h.p. for short periods. Each motor is fitted with a starting regulating, slip-ring rotor, which is completely enclosed. The rotor shaft runs in bearings of the self-oiling type.

Digitized by Google

In-by Pump and Motor at No. 3 Pit.—The pump is of the diagonal three-throw mining type, and of the following dimensions: diameter of rams, 2½in.; length of stroke, 6in.; revolutions per minute, 46. This pump is fixed with independent and interchangeable pump barrels; independent and interchangeable suction and delivery branch pipes; independent and interchangeable suction and delivery valve boxes. The rams are of gunmetal attached to substantial cross-heads, and work in slipper guides on the bed-plate. The crankshaft is of steel running in three bearings on the bed plate, and carries a spur-wheel driven by a pinion on the countershaft. The countershaft is of steel running in two bearings on the end of the diagonal frame, and carries a machine cut-steel spur wheel which is driven by a raw-hide pinion on the motor shaft. The motor for diving this pump is of the three-phase type of five effective horse-power, the speed being 960 revolutions per minute at 520 volts. The pump and motor is self-contained, and is mounted on wheels and fitted with controller complete. This pump is about 800 yards in-by at No. 3 pit. High-tension current is conveyed to a 45-kw. transformer close to where the pump works by a three-core, paper-insulated, lead-covered, steel-armoured cable trom No. 3 sub-station switchboard. The cable is placed direct in the ground, and is carried down the shaft in special pitch-pine casings, similar to No. 6 shaft. The total distance from the power station to this pump is 1,750 yards.

Engineering Shops.—The engineering shops are situated close to the power station, and all the tools are electrically driven. In most cases each machine has its own motor. The number of machines fixed is as follows: one "Cyclone" blower, 5-h.p. motor, 250 revolutions per minute; one 14in. by 20in. lathe, 3-h.p. motor, 120 revolutions per minute; one 8ft. by 4ft. by 4ft. planer, 3-h.p. motor, 250 revolutions per minute; one 10in. slotting machine, 3-h.p. motor, 200 revolutions per minute; one 6ft. radial drill, 3-h.p. motor, 200 revolutions per minute; one 2in. screwing machine, 3-h.p. motor, 150 revolutions per minute; one milling machine, 3-h.p. motor, 200 revolutions per minute; one 15lb. power hammer, 3-h.p. motor, 300 revolutions per minute; one punching and shearing, 5-h.p. motor, 250 revolutions per minute; one 200lb. power hammer, 5-h.p. motor, 250 revolutions per minute; one 6ft. plate-bending roll, 5-h.p. motor, 250 revolutions per minute; one 20in. circular saw, 3-h.p. motor, 1,440 revolutions per minute; one 30in. band saw, one tenoning machine, one mortice and boring machine, one gulleting machine, one plane knife grinder, one band-saw sharpening machine (5-h p. motor, 360 revolutions per minute); one 12in. wood planer, 5-h.p motor, 960 revolutions per minute; one 24in. wood planer, 5-h p. motor, 960 revolutions per minute; one 40in. circular saw, 5-h.p. motor, 960 revolutions per minute; one cross-cut saw, 3 h.p. motor, 250 revolutions per minute; one mortar mill, 5-h.p. motor, 250 revolutions per minute; one corn mill, 3-h.p. motor, 360 revolutions per minute; one chaff cutter, 5-h.p., 250 revolutions per minute; one Saddler's sewing machine, 1-h.p. motor, 1,440 revolutions per minute; three lamp-cleaning machines, 1 h.p, 1,440 revolutions per minute. The total effective horse-power amounts to 84. All the motors have short-circuited or squirrel-cage rotors, and are started and stopped by a triple-pole switch. These motors work on a low-tension circuit at 400 volts, three-phase. The current is taken from a 65 kilovolt-ampere three-phase transformer placed below the main switchboard in the power station.

Transformers.—Three-core three-phase transformers are used throughout. The primaries are all wound for a tension of 1,100 volts at 50 cycles per second, and are fitted with high-tension removable porcelain tube fuses with spring clip connections. The secondaries are wound for a tension of of 400 and 520 volts respectively. The 520-volt transformers are used underground and are taken as far in-by as circumstances will permit. The 400-volt transformers are used above ground, and are fitted with a triple-pole switch and four single-pole fuses mounted on a marble slab, and are "star" connected and fitted with neutral terminals, so as to get two voltages from the same windings—*i.e*, 400 volts between the phases for supplying motors and 230 volts between any phase wire and the neutral for incandescent lighting. The whole of the lighting above ground is done in this manner, frequently with "out of balance" load of 20 per cent. without any appreciable drop in voltage.

Lighting.—There are at present installed about 460 16-c.p. incandescent lamps and six enclosed long-burning arc lamps, distributed as required in the offices, various shops, engine-houses, screens Nos. 1, 3, and 6, pit bottom, and sidings.

Sub-Stations.—There are two sub-stations provided—one at No. 2 pit, distance from power station 450 yards; and one at No. 3 pit, distance from power station 790 yards. Each sub station is provided with the following switchgear and instruments mounted on white marble slabs, supported by a suitable frame of channel iron, and consists of one main feeder panel, which receives the high-tension current from the power station, and contains one high-tension three-pole oil switch, three high-tension removable tube fuses, three ammeters, three distributing panels, each with one high-tension three-pole oil switch; three high-tension removable tube fuses and three ammeters; one lighting circuit panel with six double-pole switches and fuses and three ammeters; two large-dial voltmeters fixed on the top of the switchboard, one reading up to 1,200 volts and the other reading up to 500 volts. Beneath each sub-station is fixed a 15-kw. transformer for light and power on the surface in the immediate vicinity of each sub-station.

Coal-Cutting.—Several coal-cutters of the bar type are worked from this plant, the number being increased as found convenient.

Waterworks.—One treble vertical single-acting pump, 4½in. by 6in. rams, fitted with a 5-h.p. motor working at 350 volts, supplies water to the village for domestic purposes.

The Luncheon.

After visiting the electric works, Mr. Madew entertained the company at luncheon, which was served at the George Hotel, Pinxton. Mr. Madew presided. After the health of "The King" had been honoured,

Mr. J. Mein proposed the toast of "The Pinxton Coal Company, Limited." He said they were much obliged to the directors of the company for their kind permission to see their works that day. Coal-working had been going on there since 1745, and they had seen that day an example, if he might so put it, of an old man made into a young one. He had known the company for about 12 years, and when he first knew it, it was working on the old-fashioned lines. Electricity had come to the front during the past 12 or 15 years, and the Pinxton Coal Company had not been slow to take advantage of the latest improvements and inventions. In the works that day they had seen a splendid example of enterprise, brains, and money used to cheapen the cost of production. They were much obliged to the company for having permitted them to make that visit, which had not only been interesting to those of them who were using electricity, but instructive as well as interesting to those of them who were not. He had never seen on the Continent or elsewhere in the way of electrical plant anything to exceed what they had inspected that day at the works of the Pinxton Company. They had often had it dinned into their ears that the mining men of this country lagged behind their Continental competitors. That, unfortunately, might be true, but that did not apply to the Pinxton Coal Company. Such enterprise as they had witnessed was worthy of success. He had great pleasure in coupling with the toast the name of the company's worthy and capable manager, Mr. Madew.

The Chairman, in response, said he was extremely obliged to Mr. Mein for the kind remarks he had made with regard to the Pinxton Coal Company. He could tell them that since the works were started, 18 months or two years ago, they had not had a single hitch in them. Their breakdowns had not cost them five pounds during the whole of the time. He thanked them for the kind way in which they had accepted the toast.

Other toasts of a more general character followed, and the proceedings terminated with the usual votes of thanks.

COMPANIES' MEETINGS AND REPORTS

GENERAL ELECTRIC.

The ordinary general meeting was held on the 27th ult., Mr. G. Byng presiding. Particulars of the report were given in our issue of the 22nd ult.

The **Chairman**, in moving its adoption, stated that the year's work had been difficult, as the home trade had been exceedingly quiet. The Company had maintained their turnover, and in some departments they had increased it, but they had had to expend more money in doing so. After meeting various charges, there remained a surplus which enabled the Board to propose a dividend of 7 per cent. on the ordinary shares, and a more adequate return might be anticipated when conditions improved. The Peel Works at Manchester continued to be full with orders for their manufactures. The various departments were working all the year round at high pressure in order to cope with the increased output which was necessary to maintain the old profits. The telephone department had considerably benefited by the requirements of the Government. The engineering works at Witton had justified the expectations which had been formed about them. Important orders had been secured from the War Office and the Admiralty. The position of the Company's carbon works had aroused much public interest. The Board were satisfied that they had quashed the mistaken idea that carbons could not be produced in this country. In this connection the Chairman adverted to the politico-economic aspect of the question, and expressed the opinion that a protective tariff would greatly improve matters.

The report was adopted.

ANGLO-AMERICAN TELEGRAPH.

The half-yearly general meeting was held last Friday at Winchester House, Mr. Francis A. Bevan presiding. Particulars of the report appeared in our last issue.

The **Chairman** alluded to the loss sustained through the "Minia" having to lay up for repairs. The vessel would, however, be in use again in a few weeks. There was an understanding between the stockholders and the Board that when the renewal fund amounted to £1,000,000 the directors would only add to the fund, so long as it kept at £1,000,000, the interest earned by the investments forming it. The fund at the moment amounted to £987,676, but the nominal value of the securities was £940,345, while their real value, on account of depreciation, was less than that by £33,989. From the £987,676 they ought, therefore, in order to arrive at the true position, to deduct this £33,989, leaving £953,687, of which £47,331 was held in the shape of cable stock and for working expenses, for they had no working capital. He might therefore say that their securities were worth just over £900,000, and that they had about £50,000 in stock and plant. Together these sums came to about £950,000. He concluded by moving a resolution adopting the report and authorising the directors to carry into effect the pension scheme.

Sir Gerald FitzGerald (the deputy chairman) seconded the motion, which was carried unanimously.

CITY AND SOUTH LONDON RAILWAY.

The half-yearly meeting of this Company was held on the 29th ult., Mr. C. G. Mott presiding. Particulars of the report were given in our issue of the 22nd ult.

The **Chairman** remarked that the result of the half-year's working had been better than might have been anticipated, considering that the Company had the full competition of the electric trams, with the weather all in favour of the trams. There had been a decrease in the number of passengers using the railway, but this decrease had since been partly made up by increase in the number of season-ticket holders. The 1d. fares which they had instituted had amounted to nearly one-half of the whole traffic. The directors had done their best to encourage season tickets, with the result that there were 3 339 monthly tickets issued, and there were 3,400 quarterly tickets, as against 2 500 tickets last year. The chairman observed that the tendency was in the direction of rapid travelling, and that "tubes" were not subject to speed restrictions like the tramways.

The report was adopted unanimously, and a resolution was afterwards passed sanctioning the creation and issue of £300,000 further capital, with borrowing powers to the extent of £100,000.

GREAT EASTERN RAILWAY.

At the half-yearly meeting held on the 28th ult., **Lord Claude Hamilton**, who presided, stated that in regard to electric traction the directors were watching the development of the Liverpool-to-Southport section of the Lancashire and Yorkshire Railway, besides which representatives of the Company had recently visited France to see whether there was anything to be learnt in regard to the working of the French railways. They had come back thoroughly satisfied that there was nothing in what they had seen—though a great deal that was commendable—that would prove of use to the Great Eastern Railway. They were, therefore, continuing the policy of holding their hands until they found something which they could recommend with full confidence.

DUBLIN TRAMWAYS.

The report and statement of accounts for the past half-year show increased receipts and diminished expenditure. The gross receipts totalled £128,487, being £3,322 more than the corresponding period of 1903, while the expenditure, £71,172, exhibits a saving of £2,784. The directors propose a dividend on the ordinary shares at the rate of 6 per cent. per annum, against 5 per cent. last year. This left a balance of £9,000, of which £2,000 has been placed to reserve, the same amount as last year; £3,000 has been allocated towards the cost of electric welding on the Dalkey line, and £4,015 has been carried forward, being £1,158 more than was carried forward 12 months ago.

The half-yearly meeting of the Company was held in Dublin on the 26th ult., **Mr. W. M. Murphy**, the chairman of the Company, presiding. In moving the adoption of the report, he remarked that the trouble with the rail joints on the Dalkey line had been remedied by electric welding. The tramways and equipment had been maintained in a high state of efficiency, and at the same time an economy in maintenance had been effected. The generating station had accomplished remarkable results, for though 94,587 additional units of electricity had been produced, the cost had decreased by £396. The Company were at present engaged in making a short extension of the Palmerston Park line, about 539 yards in length along the Dartry-road, and land had been acquired at its terminus for building a car-shed, which was very much wanted in the locality, as all the cars had, after their last journey at night, to return from Palmerston Gate to Clonskeagh, a distance of just two miles, and the first cars in the morning had to make a similar profitless journey. This meant a dead mileage of about 17,000 miles in the year, which would be saved by the erection of the new car-shed in Upper Rathmines. It was intended that this tramway should be continued down from Palmerston Gate to join with the Rathmines tram at the south end of Rathmines-road, but the construction of this portion was awaiting a road widening which the Rathmines Urban Council were about to carry out.

Replying to questions, the Chairman stated that the Company did not project other extensions at present, but might consider them in the future.

The report was adopted unanimously.

METROPOLITAN DISTRICT RAILWAY.

The report of this Company for the half-year ended June 30 states that the work of electrification is making rapid and successful progress. The great power station at Chelsea is virtually completed, and the

Digitized by Google

machinery is being installed. The sub-stations on the Company's lines are nearing completion. Four hundred and twenty new corridor cars, providing 60 trains, have been ordered and are being constructed. Many miles of cables have been drawn into the ducts. The litigation which has been going on for several years between the Company and the Metropolitan Railway Company, with reference to the division of traffic and the user of the western joint lines, has been brought to an end, an arrangement having been made which is believed to be mutually satisfactory. The working agreement between the two companies has been extended until such time as the railways are worked electrically, and the Company receives 57 per cent., instead of 50 per cent., of the pooled receipts, in addition to a payment for arrears. Allusion is made to the Act recently obtained enabling the Company to charge zone rates over certain sections of the railway. The three tube railways with which the District Company have interchange stations at various points—the Great Northern, Piccadilly, and Brompton Railway, the Baker-street and Waterloo Railway, and the Charing Cross, Euston, and Hampstead Railway—are being rapidly constructed, and arrangements are being made with these companies for the user of ducts through the Company's tunnels, and also for the joint user of certain sub-stations.

CENTRAL LONDON RAILWAY.

The report for the first half of the present year states that the receipts from all sources of revenue amounted to £184,962, and the working expenses to £95,126, leaving a balance of £89,836 carried to the net revenue account. After providing for interest on the debenture stock and other payments, the net revenue account shows a balance of £108,737, including £36,078 brought forward from last half-year. There was a decrease of 20,741 in the number of passengers carried on this railway as compared with the corresponding period of 1903, notwithstanding an increase of 146,490 in the number of workmen conveyed. The directors recommend a dividend at the rate of 4 per cent. per annum, and on the undivided ordinary stock and the preferred ordinary stock. After putting aside £10,468, the proportion applicable to the deferred stock—dividend on which is not payable until the result of the year's working has been ascertained—there remains an unappropriated balance of £48,737, as compared with £45,406 a year ago. This is considered highly satisfactory, having regard to the adverse conditions of the half-year. The Company is opening up a new source of revenue by letting the areas over the stations for building purposes. Only the Lancaster Gate, Notting Hill Gate, and Holland Park station sites now remain for disposal. In the certificate appended to the accounts the auditors draw attention to the desirability of establishing a fund for the depreciation of the working stock, machinery, and permanent way. Such fund has not yet been established, but a general reserve fund has been provided, which now stands at £31,262. The total number of passengers carried on the line since its opening in 1900 up to June 30 last was 169,333,806.

CROMPTON AND CO.

The report to March 31 last states that the net profits for the year amount to £14,584, and after providing for debenture interest and other items there remains, with the sum brought forward from last year, a balance of £8,054. No interim dividend was paid in January last for the half-year ended September, but the directors now propose to place £750 to the credit of doubtful debts account and to pay a dividend at the rate of 2½ per cent. for the year, carrying forward a balance of £1,221, as compared with £1,098 last year. There are now some signs of an improvement in trade. The directors have registered a company under the title of the Electric Supply Corporation, Limited, and have been engaged in obtaining business for that company. They have secured concessions or agreements in 17 towns in the United Kingdom for electric lighting and for tramways, and arrangements have recently been made for the necessary capital for carrying on the work. An agreement has been made with the new company that Crompton and Co. shall carry out all the contract work required for a period of five years at a satisfactory profit. An agreement has also been made with the Electric Supply Corporation to sell the whole of Crompton and Co.'s interest in the Chelmsford Electric Lighting Company, Limited, this company taking shares and debentures in the new company in payment. The directors have every reason to believe that the new company will be a successful one, and that the securities thus exchanged will prove a profitable investment.

CONSOLIDATED ELECTRICAL.

The report of the Consolidated Electrical Company, Limited, for the period ended March 31 last, to be submitted at the meeting on the 8th inst., states that the Anglo-Portuguese Telephone Company, Limited, in which this Company is largely interested, continues to make satisfactory progress. The Private Wire and Telephone Installation Company, Limited, which was formed to take over a branch of this Company's business, has, the directors understand, had a satisfactory year's trading. This Company holds £2,000 of debentures and a majority of the share capital of the Private Wire Company. The net revenue account of the Consolidated Electrical Company shows a debit balance of £266. The items of salaries, office expenses, etc., should show further reduction in the next accounts. For many months the efforts of the Board were devoted to the reorganisation of the Company's finances, and these eventually were placed on a comparatively satisfactory footing. The whole of the debenture debt and other heavy liabilities were paid off, and at the present moment the Company is virtually free from floating debt. The directors have also been engaged in overhauling the affairs of the manufacturing branch. Until the close of 1903 business continued fairly good, but latterly there has been a great scarcity of remunerative orders in telephone and electric lighting work, and drastic economies have in consequence been effected in the administration and general management. The office of managing director has been abolished at a saving of £800 per annum. Mr. Leonard Redmayne has succeeded Mr. E. L. Joseph as works manager, and a further saving of £500 per annum has been effected by this change. Wages and other outgoings have been largely reduced, and these economies have been effected without loss of efficiency. Their effect had not been felt at the time of closing the accounts now under review, but will be apparent in the accounts for the current year. The removal from Coventry, so long talked of, is now an accomplished fact. The extensions at Canonbury, in progress at the time the Company was reconstructed, are completed, and the factory is now in a thoroughly efficient condition.

LIVERPOOL OVERHEAD RAILWAY.

The report of the directors for the half-year ended June 30, 1904, to be submitted to the thirty-second half-yearly general meeting on 9th inst., states that the gross revenue receipts amounted to £41,927. 13s. 3d., and the working expenses to £31,739. 16s. 11d. The number of passengers carried totalled 5,624,421 against 5,514,089 during the corresponding period of last year. The traffic, both on the railway and tramway, has suffered by the decreased work at the docks owing to the small crop of cotton, but bearing this in mind, the traffic has been fairly well maintained. The traffic working expenses show a satisfactory decrease, but there has been a further outlay on renewal of the permanent way, of which £1,000 has been charged to renewal fund. It is expected that the relaying of the permanent way will be completed this year. The contract for the construction of the northern extension to the Seaforth Station of the Lancashire and Yorkshire Railway has been let, and the work is now in progress. The revenue account shows that the receipts from passenger traffic amount to £41,137. 8s. 2d., and miscellaneous receipts and interest £790. 5s. 1d—total. £41,927. 13s. 3d., which, after deducting working expenses, £31,739. 16s. 11d., interest on mortgage debentures and on calls paid in advance, £3,948. 19s. 9d., and adding balance brought forward, £4,132. 1s. 11d., leaves available for dividend, £10,370. 18s. 6d. Out of this balance the directors recommend dividends at the rate (less income tax) of 5 per cent. per annum on the preference shares, and 1¼ per cent. per annum on the ordinary shares, £3,125, leaving a balance of £4,052. 5s. 10d. to be carried forward to next half-year. The mileage worked is: train system, 6 miles 57 chains; tramways, 2 miles 40 chains. The mileage run was: trains, 366,948, against 358,757 during the corresponding period of last year; and trams 134,646, against 134,599.

WATERLOO AND CITY RAILWAY.

The report for the half-year ended June 30 last states that the gross receipts of the line, less Government duty, amounted to £17,376, and the working expenses to £8,263, being at the rate of 47·55 per cent., as compared with 46 per cent. for the corresponding period of 1903. The balance available for dividend, after providing for interest on debenture stock, is £8,521, and a dividend at the rate of 3 per cent. per annum on the ordinary stock will absorb £8,100, leaving £421 to be carried forward to next half-year. The dividend will be payable on

Digitized by Google

Aug. 13. The number of passengers carried during the past six months, exclusive of season-ticket holders, was 2,227,350, showing a decrease of 53,783 compared with the corresponding period of 1903. The season-ticket holders on June 30 last numbered 1,611, as against 1,244 at the end of June, 1903.

DUBLIN AND LUGAN ELECTRIC RAILWAY.

The report of the directors to be submitted at the forty-sixth ordinary half-yearly meeting on the 18th inst., states that the total receipts from all sources show an increase as compared with the corresponding period of 1903 of £296. 11s. 5d., being equivalent to 10¾ per cent. The total expenditure shows a decrease of £173. 6s. 8d. on the half year, being equivalent to 9½ per cent. After providing for debenture interest there is a balance available of £1,211. 1s. 8d., out of which it is proposed that a year's dividend be paid on the 5 per cent. preference shares, being 10 per cent. on the half-year, absorbing £950, and reducing the arrears on these shares to a period of nine months. It is also proposed to pay a further sum of £100 off electrical equipment (capital account), and to carry forward the balance of £161. 1s. 8d. to next half-year. A resolution will be submitted at the meeting that the sum of £2,300 now standing to the credit of reserve account, which sum has been already paid on account of electrical equipment, shall be written off the balance standing at debit of capital account. The system is seven miles in length (single track). The miles run during the half-year totalled 54,625, against 51,513 during the corresponding period of last year.

BLACKPOOL AND FLEETWOOD TRAMROAD.

The report for the half-year ended June 30 last, to be submitted at the meeting on the 26th inst., states that, including the sum brought forward from last half-year, the balance of profit, after providing for debenture interest, is £3,530, and the directors recommend a dividend at the rate of 4 per cent. per annum, writing off £500 to depreciation reserve, leaving £30 to be carried forward. The number of passengers carried during the half-year was 779,060. Receipts from all sources amounted to £10,257.

NEW COMPANIES REGISTERED.

Arnold Goodwin and Son, Limited.—Capital, £10,000. Objects: to, *inter alia*, adopt an agreement with A. Goodwin, and to carry on the business of railway proprietors, manufacturers of rails, sleepers, cables, and the like, electricians, electrical, mechanical, and general engineers, etc. Registered office: 56 and 58, Sumner-street, Southwark, S.E.

Galston Gas Company, Limited.—Registered in Edinburgh. Capital, £8,596. Objects: to purchase or otherwise acquire the business of manufacturers and suppliers of gas carried on under the name of the Galston Gaslight Company, at Garlston, Ayrshire, with all the assets thereof, and to carry on in the United Kingdom the business of manufacturers and suppliers of gas and electricity, etc.

Bastian Mercury Vapour Lamp, Limited.—Capital, £20,000. Objects: to acquire the benefit for the United Kingdom and Isle of Man of certain inventions from Bastian and Partners, Limited; to adopt an agreement with the said company and C. O. Bastian and A. E. Salisbury; and to carry on the business of mercury vapour lamp manufacturers, electricians, etc. Registered office: 39, Victoria-street, S.W.

Bowen's Electric and Motor Boats, Limited.—Capital, £20,000. Objects: to acquire the freehold yacht-building and electric works on Eel Pie Island, Twickenham; to adopt an agreement with K. Bowen; to construct and establish, in Eel Pie Island or elsewhere, a dock with patent and other slips, workshops, buildings, machinery, warehouses, and other conveniences, and to carry on the business of builders of and dealers in launches, yachts, ships, or boats of all kinds, whether propelled by electricity, steam, or other power, etc. Registered office: Northumberland-chambers, 23, Northumberland-avenue, W.C.

Empire Oil-Engine Syndicate, Limited.—Capital, £20,000. Objects: to acquire the inventions of J. Clay (for which provisional protection, No. 26,403 of 1903 and No. 11,971 of 1904 have been granted), relating to internal-combustion engines, together with the right to apply for patents in respect of the said inventions for all countries and colonies, and to adopt two agreements—(*a*) with E. R. Royston and J. Clay, and (*b*) with H. H. Perkes and W. Murray, and to carry on the business of manufacturers of and dealers in oil, steam, electric, and other engines and motors, motor vehicles, cycles, and vessels of all kinds, general engineers, etc. Office: 7, Great St. Helens, E.C.

Liens Registered.

Electrolytic Alkali Company, Limited, Middlewich.—Trust deed registered July 25 for £50,000 debentures. Trustee: Liverpool Mortgage Insurance Company, Limited; charged on freehold property in Middlewich and all other assets for the time being, including the uncalled capital.

British Electric Calibrated Fuse Company, Limited.—Issue on July 23 of £400 5 per cent. debentures, part of a series created Dec. 4, 1903, to secure £3,000, charged on the company's undertaking and property, present and future, including uncalled capital. No trustees. Total amount previously issued of same series, £1,750.

Perth Electric Tramways, Limited, London, E.C.—Liens registered July 5 for £34,900 6 per cent. debentures, part of £50,000; amount previously issued, £100; charged on the benefit of certain agreements, deposit, provisional order, and Acts of Parliament, tramways and tramway undertaking, plant, machinery, etc., in Perth, West Australia.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Manchester.—The Electricity Committee invite tenders for the supply, delivery, and erection at their Dickinson-street generating station of high and low pressure piping for two 750-kw. turbo-generators. Tenders by 10 a.m. on 9th inst.

Dublin.—The Lighting Committee of the Corporation of the City of Dublin are prepared to receive tenders for the supply of 500 alternating-current meters, single-phase and three-phase. Tenders to the Chairman, Lighting Committee, 3, Cork-hill, Dublin, by 12 noon on Aug. 23.

Plymouth.—The Corporation invite tenders for (25) steam alternator, etc.; (26) Lancashire boilers, with mechanical stokers; steam, exhaust, and other piping; ejector, condenser, valves, etc. Specifications, etc., may be obtained from the Borough Electrical Engineer. Tenders by Aug. 15.

London, S.E.—The Bermondsey Borough Council invite tenders for the wiring of the staircases and courtyards of the Fulford-street dwellings. Specifications, etc., may be obtained from Mr. Fredk. Ryall, town clerk, Town Hall, Spa-road, S.E. Tenders to be delivered at the Town Clerk's Office by Aug. 8.

Leeds.—The Corporation invite tenders for the supply of two 1,000-kw. turbo-alternators, with condensers, exciters, and high and low tension switchgear for same. Forms of tender, etc., can be obtained from Mr. J. B. Hamilton, general manager, Standard-buildings, City-square, Leeds. Tenders to the Town Clerk by 10 a.m. on Aug. 15.

Beverley.—The Visiting Committee invite tenders for various work in connection with the provision of new fire appliances at the asylum, including internal electric fire-alarm communications. Specifications, etc., may be obtained on and after 25th inst. at the office of Messrs. Maxted, Kuott, and Coles, engineers, Burnett-avenue, High-street, Hull. Tenders by 12 noon on Aug. 10.

Penang.—The Municipal Council of George Town, Penang, invite tenders for the supply and delivery of tramcars, complete with motors, controllers, trolleys, etc. Specification, etc., can be obtained at the offices of Messrs. Preece and Cardew, 8, Queen Anne's-gate, Westminster, S.W. Tenders to Mr. R. M. Christie, 4, East India-avenue, London, E.C., by 12 noon on Aug. 24.

Perth.—The Corporation invite tenders for the construction and equipment of about 4¾ miles of route length of tramways, constructed as single line with passing places—viz.: (1) permanent way and paving, including copper bonding; (2) overhead equipment; (3) cables, ducts, etc.; (4) cars and equipments; (5) car depôt building. Specifications, etc., can be obtained from the Town Clerk. Tenders before noon on Aug. 16.

Digitized by Google

Argentina.—The *Boletin Oficial* contains a notice on behalf of the Government calling for tenders for presentation by Sept. 13 for the construction of a net of electric tramways between the Plaza de Mayo, Buenos Ayres, and the suburbs of Ortusar, Devoto, and General Urquiza. The *Boletin* containing the above notice may be seen on application at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, E.C.

Greenwich.—The London County Council invite tenders for the manufacture, delivery, and erection at the tramways electricity generating station at Greenwich of the following plant: two 24in. centrifugal pumps and motors, one 3in. centrifugal pump and motor, two 8in. by 8in. three-throw air-pumps and motors, one 3in. artesian well pump, fixed and rotary strainers, etc. Specifications, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 4.

Manchester.—The Directors of the Manchester Dock and Warehouse Extension Company, Limited, invite tenders for the wiring (for power and light) and electric lighting of five transit sheds (now in course of erection) on the southerly side of dock No. 9, in the county borough of Salford. Specification, etc., can be obtained at the office of Mr. W. H. Hunter, chief engineer to the Manchester Ship Canal Company, 41, Spring-gardens, Manchester. Tenders to Mr. F. A. Eyre, secretary, Manchester Ship Canal Company, 41, Spring-gardens, Manchester, by 10 a.m. on Aug. 30.

Australian Commonwealth.—Tenders will be received at the office of the Deputy Postmaster-General, Hobart (Tasmania), until noon on Sept. 30, 1904, for the supply and delivery at the General Post Office, Hobart, of one multiple metallic branching switchboard. Specifications may be seen at, and tender forms and conditions obtained from, the General Post Offices at Hobart, Melbourne, Sydney, Adelaide, Brisbane, and Perth. Tenders should be endorsed "Tender for Switchboard," and addressed to the Deputy Postmaster-General, Hobart. Tenders may be deposited in the tender-box at the General Post Office, Hobart, or, if sent by post, must be prepaid and registered. Tenderers must state the name of the country in which the switchboard will be manufactured.

Reichenberg (Austria-Hungary).—The project for the establishment of a central distributing electric power and light plant in the Reichenberg land district has taken definite form. The territory included is about 10 miles square, and 24 towns and villages have joined in the movement and subscribed to the capital stock. Some 10 more are expected to join. The population of the district, exclusive of Reichenberg, is about 60,000. Stock is subscribed at present to the amount of £40,000, and this it is proposed to increase to £80,000. The principal purpose of the corporation will be the distribution of electric light and power, with the possibility of installing and working a system of suburban electric tramways. Tramway and light franchises for the city of Reichenberg are at present owned by private corporations, and at their expiration it has been generally supposed that the city would take over and conduct the enterprises. Negotiations are pending, however, which may change the situation in this respect. Communications regarding equipment, etc., may be addressed to directors Alfred Ginskey, Maffersdorf, and Dr. Richard Pirkl, Reichenberg.

RESULTS OF TENDERS.

Handsworth.—The order for 286 tons of bitumen has been placed with Rowland Carr and Co., through Johnson and Phillips.

Bromley.—The Borough Council have accepted the lowest tender, that of H. J. Godfrey, Balham, S.W., at £634. 6s., for the electric light at the dust destructor works.

Lancaster.—The Electricity Committee have accepted the tender of Aiton and Co., London, amounting to £229. 6s. 6d., for the new steam main to connect the old and new boiler at the electricity works.

Islington.—The Electric Lighting Committee recommend that the tender of W. J. Oakley, 9, Walbrook, at £210, be accepted for the supply of tail-rods for the three 1,000-h.p. engines at the electric lighting station.

Deptford.—The tender of the Electrical and Ordnance Accessories, Limited, Birmingham, at £340, has been accepted for the switchboard and connections at the town hall, and the tender of the Phœnix Dynamo Manufacturing Company, Bradford, has been accepted for the engines, dynamo, and booster in connection with the electric lighting.

London.—The London County Council Education Committee have received the following tenders for electric motor for propulsion apparatus at Culloden-street School, Poplar:—

Electrical Company, Limited, 121, Charing Cross-road, W.C.*	£103	0	0
J. Eason and Son, Fetter-lane, E.C.	192	3	9

* Recommended for acceptance with an addition of £9. 15s. for iron case.

Recent Orders.—We are informed by Browett, Lindley, and Co. that they have recently booked the following orders: J. Wrigley and Sons, paper manufacturers, Bury, a 430-b.h.p. two-crank compound engine; Mather and Platt, Manchester, for the Prestwich Asylum, 270-kw. engine; General Electric Company, Manchester, 33-kw. engine for Cairo Mill, also a 33-kw. engine for Cromer Mill, Middleton; Johnson and Phillips, Kent, 25-kw. engine; Mather and Platt, for the Admiralty Dockyard, Simons Bay, two 250-kw. engines; Industrial Engineering Company, Hyde, one 25-b.h.p. engine for the Magnesium Metal Company, Patricroft; Dick, Kerr, and Co., for the Gosport and Fareham trams, three 600-b.h.p. engines, each complete with surface condenser; Johnson and Phillips, for the Abosso Gold Mining Company, one 31-kw. engine; Trafford Power and Light Supply Company, one 15-b.h.p. engine; Dick, Kerr, and Co., for Bangkok, three 200-kw. engines; War Office, for the Royal Woolwich Arsenal, 500-kw. triple-expansion engine coupled to a generator by the British Westinghouse Company, complete with surface-condensing plant.

London, N.W.—The St. Pancras Electricity and Public Lighting Committee have received the following tenders for supplying and erecting a low-tension switchboard at the King's-road station:—

T. W. Broadbent	£798	0	0
Ferranti Limited (receivers and managers)	900	0	0
J. G. Statter and Co.	1,026	0	0

* Recommended for acceptance.

BUSINESS NOTES.

LIGHTING AND GENERAL.

Bilston.—The District Council have decided to have a telephone laid on at the town hall.

Swindon.—The Town Council propose to spend some £6,000 on extensions of the electric supply plant.

Birkenhead.—The electric lighting undertaking shows a net profit for the past 12 months of £1,386, as against £1,195 the previous year.

Chelsea Electricity Supply Co.—The directors have declared an interim dividend at the rate of 4½ per cent. per annum on the ordinary shares.

Hull.—An enquiry has been held into the Corporation's application for sanction to a loan of £10,000 for additional machinery. There was no opposition.

Electrical Coal-Cutters.—Electrical coal-cutting machines have ben introduced, among several Lancashire collieries, into one of Lord Ellesmere's mines.

Panama.—The National Convention is reported to have voted a sum of £325,000 for various public works, including an extension of the electric lighting system.

Swansea.—The Town Council have decided to make formal application to the Local Government Board for sanction to borrow £2,000 for extension of telephone cables.

Digitized by Google

Bideford.—The Mutual Electric Supply Corporation and Southern District Electricity Corporation have notified their intention of applying for lighting orders for Bideford.

Bexhill.—The Corporation, according to report, recently decided by a large majority to continue the electric supply undertaking themselves, instead of selling it to a private company.

Vickers, Sons, and Maxim.—The directors have declared an interim dividend for the half-year ended June 30 last of 1s. per share on the 3,689,500 ordinary shares, fully paid.

Promenade Concerts.—The Newman promenade concerts at Queen's Hall will be resumed on Saturday next, for which evening a full and interesting programme has been arranged.

Penge.—The Urban District Council have received notice from the Blackheath and Greenwich Electric Light Company of the laying of cables for electric lighting from Westow-hill to Palace-hill.

Charing Cross and Strand Electricity Supply Co.—The directors have declared an interim dividend on the ordinary shares at the rate of 8 per cent. per annum for the half-year ended June 30.

Sydney (N.S.W.).—Electric light works of sufficient magnitude to supply nearly all the streets and buildings of the city are reported to have been started, thereby opening a considerable field for electric lamps.

Strokestown (Ireland).—A new concern, entitled the Strokeatown Electric Lighting Company, has been formed to whom will be transferred the plant and undertaking hitherto conducted by an enterprising inhabitant.

Devonport Dockyard Inspection.—The annual inspection of the electrical and torpedo stores at Devonport Dockyard and Bull Point naval ordnance depôt has just been completed, a thorough examination of all the apparatus having been made.

Scothill Nether.—Owing to the high price charged for gas by the Dewsbury Corporation, the Urban District Council have enquired of the Yorkshire Electric Power Company the terms upon which they will supply electricity in bulk for lighting and power.

Maydock.—The District Council have decided to apply for a provisional order for supplying energy, the opinion being expressed that it would enable them to obtain better terms from the Lancashire Electric Power Company, who are desirous of providing energy for the town.

Llantrisant and Llantwit.—The District Council have received notice from Mr. C. V. Fowler that he intends applying for a provisional order under the Electric Lighting Act for the district of Llantrisant. The clerk was instructed to write asking him for particulars of his scheme.

Aston.—The Electricity Committee have adopted the following resolution: "That the Council delegate to the Electricity Committee executive powers for the working, management, and control of the electric power station, the committee reporting thereon from time to time to the Council."

Stock Exchange.—The date appointed for the special settlement in respect of the London United Tramways (1901) 25,000 5 per cent. cumulative preference shares of £10 each, Nos. 100,001 to 125,000, is the 17th inst. An instalment of 15 per cent. is due to-day upon the London County 3 per cent. consolidated stock.

Spennymoor.—The Northern Counties Electricity Supply Company have secured the contract for the street-lighting of the whole district for the season of 10 months at £2. 7s. 6d. per lamp. Their former contracts with the Council have been for portions of the district only, the remainder being illuminated by the gas company.

New Premises.—Messrs. A. Vandam and Co., of Johannesburg (late Vandam, Marsh, and Co., Limited, of 15, Gerrard-street, Soho), inform us that they have opened a warehouse and offices at Johannesburg, where they have a large stock of electrical supplies on show. Their postal address is P.O. Box 4,941, Johannesburg.

Hanley.—All the electric lights went out for a few minutes on Saturday, and the Chairman of the Electricity Committee remarked that the incident illustrated the importance of obtaining the new engine, now under order, so as to be ready for the winter. It appears that the lights were extinguished through an armature coil being burnt out.

Lancaster.—The Rural District Council have received an application from the Hamsterley Colliery Company for permission to erect an electric cable along certain roads. The proposed route crosses a turnpike road, and the Council have decided to instruct their solicitor to draft a clause so as to protect the Council in case of the cable causing accident to life.

Datchet.—At a meeting of the inhabitants the following resolution was adopted: "That the Parish Council be authorised and is hereby empowered to enter into a five years' contract with the Slough and Datchet Electrical Supply Company to light the parish of Datchet upon the terms quoted to the Parish Council by the electrical company—£147 per year for five years."

Stoke-upon-Trent.—An agreement has been entered into between the Corporation and the canal engineer respecting the laying of cables along the towing path, the Council to pay an annual wayleave of £1. Mr. G. V. Fowler having given notice of his intention to apply for a provisional order under the Electric Lighting Acts, the Council decided to oppose any such application.

Newhaven.—The Urban Council have instructed the town clerk to reply to the Southern District Electricity Corporation and Mr. Fowler that if they will submit draft agreements embodying the terms under which they propose to apply for provisional orders for the supply of electricity in the district, the Council will consider whether they can give their sanction to the application.

Farnborough (Hants).—The Urban District Council have received a letter from Mr. G. Vaughan Fowler, with reference to the electric lighting order, enquiring if the Council were prepared to negotiate for the transfer and a lease of the order. The Council are not disposed to entertain the proposal.

Longside.—The Electricity Committee, after making enquiries into the question of letting motors on hire, recommend that the motor hire-purchase system be adopted, and that an agreement be entered into with the British Thomson-Houston Company to supply their motors in accordance with terms submitted, and that descriptive booklets be distributed among likely users of motive power.

Caerphilly.—The Bill to confirm the provisional order made by the Board of Trade to confer electric lighting powers on the District Council, which has passed the House of Commons Committee, was again opposed by the Rhymney, etc., Gas Company when the Bill came before the House of Lords Committee on Wednesday, but after a very brief deliberation it was allowed to proceed.

Stoke.—The Buildings and Estates Committee of the Guardians have considered the question of the substitution of electric motors for steam-engines at the school, well, and hospital laundry. They point out that the cost of the electricity would be practically nil, as the dynamo would run full load instead of half load as now, and that £100 a year would be saved. The cost of the motors is estimated at £150.

Tiverton.—Messrs. Suter and Co., contractors for the electric light under the Town Council, have issued a circular to householders and traders setting forth the advantages of electricity both for lighting and motive work. The price proposed to be charged for lighting is 5½d. per unit. The cost of installing electric light in a house will be 12s. 6d. per lamp, and a charge of 10s. per annum will be made for meters.

Bermondsey.—The Borough Council have agreed to the recommendation of the Electric Lighting Committee that an additional feeder in connection with the Rotherhithe extensions be purchased at a cost of £3,100, the money to be raised by loan and charged to the capital account. The Guardians have approved an agreement with the Borough Council for the supply of electricity to the infirmary at the rate of 3½d. per unit.

Poplar.—A recommendation of the Finance Committee, that the sum of £3,908. 0s. 8d., being the credit balance on profit and loss account of the electricity undertaking at March 31, 1903, be transferred to a reserve fund account, in order to provide for renewal of plant, has been referred back, a councillor desiring to know what had become of a sum of £4,000 which was to have been placed to the electrical reserve account.

Electricity and Lighthouses.—The Bournemouth and Poole Electricity Supply Company, Limited, having written that the charge for installing an electric light of 200 c.p. in the Lilliput Lighthouse would be £13. 10s., and that the charge for current would be at the rate of 3d. per unit, which would amount to £55 per annum, the Lighthouse Commissioners have replied that the cost would be too high to justify them in adopting the proposal.

Luton.—At the last meeting of the Electric Light and Power Committee the electrical engineer reported that the Council now had a total of 174 consumers with 10,990 lamps and 53 motors of 179 h.p., and that at the present time over 648 additional lamps and five motors of 18½ h.p. were being wired. He also reported that the number of units generated showed an increase of 37 per cent. over the number generated during the corresponding period of last year.

Belfast.—At this week's meeting of the Electricity Committee the electrical engineer (Mr. V. A. H. M'Cowen) presented a summary of the electric light rental for the six months ended June 30 last, which showed that the amount received for current was £13,887. 4s. 7d., as compared with £11,940. 2s. 8d. at the corresponding date last year, or an increase of 16·3 per cent. The average price per unit for the six months was 2·767d., as compared with 3·066d.

Wrexham.—The Guardians have adopted the suggestion of the electrical engineer that an electric alarm be fixed to the flood gates in the river bed adjoining the electricity works as an experiment. The Electricity Supply Committee reported that during the month 27,940 units had been consumed, compared with 29,094 last year. The committee fully discussed the extension scheme, and it was decided to send a committee to inspect the Chester scheme.

Bo'ness.—The Town Council have signed the agreement with the National Electrical Construction Company, Limited, the contractors for the electric lighting of the burgh. The agreement provides that the works are to be completed within the next nine months, and that the Town Council are to pay to the contractors a sum of £24,689, subject to deductions, amounting to over £1,200, for, among other things, a site for the generating station recently purchased by the Town Council.

Southwark.—The accounts of the electricity department for the year ending March 31 show a total income of £12,231 against working expenses of £7,279, leaving a gross profit of £4,952—an increase of £1 343 over the previous year. Interest and sinking fund absorb £4,728, leaving a net profit of £224. The units sold numbered 793,418, of which 538,832 were taken by private consumers, the remainder being used for public lighting. The public lamps now supplied total 582, the majority of which are Nernst lamps.

A.E.G. English Manufacturing Co.—We are informed by the company that they are now starting business at 4, New Compton-street, Charing Cross-road, where a large stock will be kept. This company has acquired the English Nernst lamp patents from the A.E.G. of Berlin, and will look after the Nernst lamp business in England. All lamps and burners will in future be marked "Aegma." Owing to the rapidly increasing demand for Nernst lamps it is intended to build a factory in this country. A price list containing many novelties will be issued in a few days' time.

Digitized by Google

Keighley.—The Local Government Board has held an enquiry into the application of the Corporation for sanction to borrow an additional £11,500 for electricity purposes. The statistics put in showed that the estimated population at the present time is 43,250, the assessable value £134,296 and the outstanding loans £229,599. The expenditure already made on electrical works and plant has been £39,356. During the year ended June 30, 184,307 units had been sold, 70,008 being for motive power. There was no opposition.

Trade Notice.—We are informed by Mr. A. H. Hunt, of 115-117, Cannon-street, E.C., that the agency which he has conducted for the Walsall Electrical Company has been determined by mutual consent, though he still represents Messrs. Webb, Shaw, and Co., of Stourbridge, and also Messrs. Geoffroy and Delore. Mr. Hunt intimates that he has made arrangements by which he can still supply promptly and at favourable prices such appliances as dynamos, motors, arc lamps, switches, switchboards, instruments, circuit breakers, and iron-cased goods for high-tension and power work.

Dodworth.—Pursuant to a resolution passed by the Urban District Council at a special meeting held on the 11th ult., a public meeting of the ratepayers of the township was held on the 27th ult. "for the purpose of considering the question of the proposed public lighting of the urban district of Dodworth, and also of deciding what steps, if any, should be taken in regard to the said matter." Ultimately a proposal that gas should be used was negatived, the majority favouring the chairman's suggestion that electric lighting might be obtained in due course from the Yorkshire Electric Power Company.

Burnley.—At its meeting on Wednesday the Town Council had before them a recommendation by the Electricity Committee that the charges for meter rents should be reduced. For meters up to and including 50 amperes it is proposed to charge 6d. per quarter, and for meters over 50 amperes 1s. per quarter. Hitherto the charge has been 2s. 6d. per quarter for all sizes of meters. This movement is attributable to the action of the chamber of commerce and the tradesmen's association. The Electricity Committee were unable to entertain at present a request that the general electricity charges should be reduced.

Underground Telegraph Cables.—The following is the Postmaster-General's reply to a question by Sir Thomas Dewar as to what point the present system of underground telegraph cables to the North has been advanced, and whether the area which has suffered specially through storms in former years has now been passed: "The pipes in the underground system to the North have been laid as far as Carlisle, and also over Beattock incline. Wires in the pipes have been provided as far as Liverpool, Manchester, and Leeds, and are now being provided in the Warrington-Carlisle section. The original section—viz., that between London and Birmingham—traversed the area which had suffered especially through storms in former years."

Cork.—The following letter has been received from St. Martin's-le-Grand by the hon. secretary of the Cork Incorporated Chamber of Commerce and Shipping: "I am directed by the Postmaster-General to acknowledge the receipt of your letter of the 23rd inst., in which you forward a copy of a resolution of the Cork Incorporated Chamber of Commerce and Shipping relative to the extension of the trunk telephone system to the principal towns in the South of Ireland, and in reply to say that a scheme for providing telephonic facilities in the district in question is now under consideration. Estimates of the cost are being obtained, and steps taken to ascertain what support will be forthcoming at several of the towns mentioned by you."

Wolverhampton.—An enquiry has been held by Colonel A. G. Durnford, R.E., on behalf of the Board of Trade, into an application by the Corporation for sanction to borrow £13,000 for the purpose of electric lighting. Evidence was given by the town clerk, the borough accountant, and Mr. C. E. C. Shawfield, the borough electrical engineer. The sum of £3,000 was required for the provision of an electric generating plant at the new refuse destructor in Crown-street; £2,800 would be spent on feeder and distributing mains to deliver the electric current into the existing network of mains to supply a large manufacturing district in the vicinity of the destructor; and the balance of £7,200 would be utilised for the extension of mains throughout the borough.

Grimsby.—At a meeting of the Grimsby Electric Lighting Committee last Friday it was reported that there had been an increase of 3,212 units for traction during June as compared with last year, and 8,606 units for private consumers. In the first quarter of the year 16,570 units were sold for power purposes, as compared with 16,519 during the whole of the year 1903-4. The Chairman, in moving the adoption of the annual report, pointed out the rapid progress that had been made. From the report they anticipated that the thing would pay its way. They had thought if they sold one million units they would be master of the whole thing, and they had now got within a hair's-breadth of that. He considered the small coal bill a subject for congratulation. The report was adopted.

Inverness.—A largely-attended meeting of consumers of electric light was held last Friday in reference to a circular received from Claud Hamilton, Limited, who supply the current, and who, it appears, have intimated that the current will be discontinued unless the consumers comply with a certain demand. The consumers agreed not to take any notice of the demand made by the company. It was agreed to petition the Town Council with reference to the matter, and to ask them to take public action. The curious position of the consumers and the company has excited considerable interest in the town, and as the 10 days have now expired, the question is discussed whether the intimation in the letter, that the electric current will be cut off, will be given effect to. The subject, it is understood, will be considered by the Town Council.

Sheffield.—The Electric Light Committee having considered a report by Mr. S. E. Fedden, the general manager of the electric supply department, decided to recommend the Corporation to reduce the charges for electrical energy for power purposes as from Dec. 26, 1904, as follows: for all power used in motors, driving hoists, cranes, passenger lifts, and similar machinery, 2d. per unit; for other motors, 1½d. per unit; to consumers satisfying the general manager as to the continuous running of their motors throughout the whole of the working hours of each day, whose consumption does not exceed 5,000 units per annum, 1½d. per unit; and to consumers complying with the preceding clause whose consumption exceeds 5,000 units per annum, 1d. per unit. Discount on a graduated scale will be allowed.

Southampton.—The accounts of the electric supply department for the year ended March 31 show that the gross receipts amounted to £27,639, with an expenditure of £14,124, the gross surplus being £13,515. Interest and sinking fund take £8,704, leaving a net profit of £4,811, part of which has been applied to meeting the cost of re-erecting at the new station the plant removed from the old works, which is running satisfactorily. Latterly the tramways have been partially supplied from the new works. The committee pay a tribute to the work of Mr. H. F. Street (the borough electrical engineer) and his staff. The units sold totalled 1,298,013 against 1,752,013 in the previous year. Private consumers accounted for 654,034 units, public lighting took 137,353 units, while the tramways were responsible for 1,298,392 units. The number of consumers continues to increase.

Belfast-to-Londonderry Telephone.—At the meeting of the Londonderry Chamber of Commerce the subject of the trunk telephone service from Belfast to Londonderry, *via* Ballymena and the local service in Londonderry, was discussed. A trunk telephone service is being laid by the Post Office authorities from Belfast to Londonderry; but when the line reached Londonderry it would be almost useless, one of the members remarked, unless the local service in the city was changed by the National Telephone Company into a loop-line service. If this change be not made, subscribers will have to go to the post office when they wish to communicate with Belfast, whereas if the city local service were made into a loop line, subscribers could communicate with Belfast from their own offices. It was suggested that the chamber should request the Corporation in any negotiations they had with the National Telephone Company to insist upon this loop-line service in the city being made.

Stourbridge.—At the meeting of the Urban Council, the Electric Powers Committee reported that the Board of Trade had intimated that they would defer consideration of the question of revoking the Council's electric lighting order for 12 months. Notices under the Electric Lighting Act, 1882, of intention to apply to the Board of Trade for provisional orders to supply electricity within the Council's area had been received from two London companies. The committee would take the necessary steps to safeguard the interests of the Council. Notice had been given to the Bromsgrove Rural Council of the Stourbridge Council's intention to ask for a provisional order to confer extended powers on them under the Electric Lighting Acts. A draft agreement had been submitted by the Midland Electric Corporation for Power Distribution, Limited, for the proposed supply of electricity in bulk to the Council. Nine tenders for the laying down of electric mains had been received by the committee, who recommended the acceptance of one of these conditionally on the sanction of the Local Government Board to a loan for the purpose. The clerk read a letter from the Government Board with regard to a further public enquiry on the subject of loans for the supply of electricity, the Board intimating that the Council should be prepared to show there was such a demand for the electric light as would justify them in carrying out the work.

Croydon.—The Corporation have reduced the price for current supplied to places of public worship to 4d. per unit. The price hitherto charged has been 4½d. per unit. The committee are obtaining particulars with a view to considering the practicability of making some concession also to private consumers. The borough electrical engineer reported: Current sold this year for private lighting, 72,611 units (corresponding period last year, 51,141); public lighting, 26,629 (24,948); traction, 103,426 (92,080). A 200-kw. motor-alternator is to be bought for use during the hours of light load for the alternating-current supply, to save running an extra engine, so reducing the running costs during this time. By the use of this machine it is estimated there will be a saving in coal consumption of not less than £300 per annum. The estimated cost of motor-alternator and switchgear and cables is £1,350. The following is an estimate of capital expenditure required during 1904-5: For works—one direct-current generator, £7,000; foundations, etc., for same, £400; switchgear for new generator, £250; contingencies (10 per cent.), £765; motor-alternator, £1,100; switchgear for same, £250—total, £9,765. Of the foregoing estimate, £8,415 is part of the sum of £70,950 adopted by the Council on July 27, 1903 (of which sum of £70,950 sanction has already been received to the borrowing of £27,975), the remaining £1,350 representing the cost of the motor-alternator referred to above.

London Gazette.—The partnership between James Carson and Herbert Francis Borman, carrying on business as engineers at Hooper-street, Spring Hill, in the city of Birmingham, and trading as Carson, Borman, and Co., has been dissolved by mutual consent. The partnership between Lewis Percy Brenchley, Arthur Brenchley, and Harold Frederick Holman, carrying on business as general, electrical, and mechanical power engineers, at 36 and 38, New-street, Ashford, trading as Brenchley Bros. and Holman, has been dissolved by mutual consent. A general meeting of the members of the Electric Construction Corporation, Limited, will be held at 109, Dashwood House, New Broad-street, London, E.C., on Sept. 29, 1904, at 12.30 p.m., for the purpose of having an account laid before them, showing the manner in which the winding up has been conducted and the property of the corporation disposed of. A receiving order has been made out on creditors' petition in the estate of Warner and Co., builders and electricians, 12, Holbein-place, Sloane-square, London. The first meeting will be held at 12 noon on Aug. 11, 1904, at the Bankruptcy-buildings, Carey-street, London. A receiving order has been made out on debtor's petition in the estate of John William Thomas, engineer,

Digitized by Google

trading as Spetch and Thomas, and carrying on business at West End Mills, Longside-lane, Bradford. The first meeting will be held at 3 p.m. on Aug. 12, 1904, at the Official Receiver's Chambers, 29, Tyrrel-street, Bradford.

Annual Outing.—The first annual outing of the engineering staff and employés of the Ealing Corporation electricity department was held on Saturday last. The party, numbering 33, made an early start from Ealing for Windsor by the Great Western Railway, proceeding thence by steam launch to Marlow, where they arrived at 11 a.m. A cricket match was commenced between the "inside" and "outside" staffs, an adjournment being made at 1 o'clock to the Crown Hotel, where the company did justice to an excellent repast provided by Mr. J. Douglas Knight (borough electrical engineer) and Mrs. Knight. At this function the chair was occupied by Mr. Knight, with Mr. A. E. Pullen as vice-chairman. The greater part of the afternoon was taken up with the cricket match, a good game resulting in a victory for the "outsides," for whom Messrs. A. E. Pullen, Ablee, and Stockley showed good form with the bat, while on the other side Messrs. Payne and Hudson were most successful with the willow. In the tug-of-war which followed, however, the "insides" turned the tables after a keen contest, twice hauling their opponents over the line. The party returned to the Crown Hotel at 5 o'clock for tea, and at 6.30 p.m. a start was made for home. During the journeys out and home an excellent entertainment was furnished by the musical section of the party, Mr. Hudson presiding at the piano, while Messrs. Gordon, Watts, Payne, J. House, and others contributed to the harmony. Ealing was reached shortly before 11 p.m., a thoroughly enjoyable day having been spent by all.

Erith.—The Electric Lighting Committee's report recommends that a lamp be placed at the entrance of the passage way near Bedonwell-hill. The whole of the quarter-ampere Nernst burners on the street lamps have been replaced by two incandescents of 8c.p. each. The committee having considered the resident electrical engineer's report upon the distribution system, endorse his recommendation that an additional transformer of 100-kw. capacity be installed, and that the estimate of the British Electric Transformer Company be accepted. The committee have fully considered the question of the extension of the mains for private lighting in Lower-road, Belvedere, and also in Mayfield-road and Poplar-mount. The resident engineer's estimate for these extensions, including the necessary transformer station, amounts to £461. 19s. 5d. As a number of applications for the supply of current have been received from the owners or occupiers of houses in Lower-road and Mayfield-road, including the Education Committee for their offices and the pupil teachers' and cookery centres at Picardy, the committee recommend that supply mains be laid in these roads and the necessary transformer station provided. The committee will also be prepared to recommend the laying of a main in Poplar Mount and other roads in the vicinity upon receiving sufficient applications for the supply of current to justify the expenditure. The resident engineer has applied to have certain alterations made to the offices at the electric light station, and the committee have approved of the engineer's suggestions. The contractors have been instructed to commence the additions to the generating station.

Islington.—The following reports and recommendations of the Electric Lighting and Finance Committees respectively will be considered at to-night's meeting of the Borough Council: (1) "The electrical engineer has informed us that a supply of electricity will probably be required at the postal sorting office which is being erected in Goodwin-street, Foothill-road, but before making the actual application, the Post Office authorities desire to be informed whether in the event of their requiring the current, the Council would be prepared to make the necessary extension of mains at their own cost and to dispense with the usual statutory requisition. The cost of laying the requisite main is estimated at £300, and the probable revenue at at least £125 per annum. We recommend that the Post Office authorities be informed that in the event of their requiring a supply of electricity for the premises referred to, the Council will lay the necessary mains and will dispense with the usual statutory requisition." (2) "We have had under consideration a letter from the London County Council intimating that they are prepared to accede to the Council's application for sanction to the borrowing of the sum of £15,636 for electric lighting purposes, upon an undertaking being given that during the currency of the loan all replacements and renewals of plant, machinery, and works purchased by money raised under the sanction shall be defrayed out of the sinking fund to be provided for that purpose, or from maintenance account. We recommend that in the event of the London County Council sanctioning the borrowing of £15,636 for electric lighting purposes for a period of 42 years, the Islington Borough Council hereby undertake that during the currency of the loan no further loans will be raised to replace any of the plant, machinery, and works the cost of which is to be defrayed out of such loan, and that any renewals required during the period thereof shall be provided out of a sinking fund to be created for the purpose or from maintenance account."

Insurance.—The following are details of the revised rules issued by the Associated Fire Offices for electromotors, and dynamos used in connection therewith, employed in textile and corn mills and other buildings where motors are exposed to dust, to which we referred in our last week's issue: "(1) Motors when not in an engine-room or in a separate compartment expressly set apart for their use and built of or lined with incombustible material must be completely enclosed in an efficient metal case forming part of the designed construction thereof. Ventilation by direct communication with the outer air or by openings in the vertical portion of the metal case protected by two thicknesses of approved wire gauze is allowed. Induction motors may have unprotected ventilation openings in their metal cases, the superficial area of each opening not exceeding ¼in. and the openings being at least ¼in. apart. Slip rings and brushes or any other sliding contacts must be completely enclosed in metal cases. Inspection holes fitted with plate glass are allowed. (2) No unprotected woodwork or combustible material must be within 18in. of any motor, and wood flooring beneath any motor must be protected by a sheet of metal. (3) The motor pulley (or other mechanical device for transmitting power from the motor) must be external to the metal case enclosing the motor. Only the shaft and the connecting conductors may be carried through into the metal case or through the wall of the compartment. No belts, ropes, or other corresponding gear may be so carried. (Note.—Holes in the case to admit connecting conductors must have proper bushings, and exposed terminals must have proper protecting caps fitted to prevent short-circuiting; each connecting conductor must be provided with a proper switch and proper cut-out.) (4) Dynamos must be treated as motors. (5) Resistances and starting transformers must be similarly situated, and must be enclosed as required for motors. (6) All metal cases, tubes, etc., must be efficiently connected to earth. (7) Motors must not be supplied with current from dynamos or conductors having an earth return."

TRACTION.

Bradford.—The receipts from the electric cars on Bank Holiday amounted to £1,379.

Bournemouth.—The electric tramways achieved a record on Bank Holiday, over £500 being taken.

Dover.—After a long sitting the Town Council decided to settle the question of Sunday running by *plébiscite*.

Scarborough.—The laying of the tramways on the approach road to the Marine Drive has been deferred until the autumn.

Salford.—The Corporation have adopted a resolution directing the Tramways Committee "to furnish the cars with an efficient system of ventilation."

Erith.—It is expected that the engineer's report on the tenders for the tramways will be received in a week or two, when a special meeting will be held to consider them.

Aston.—The Board of Trade have approved the reconstructed tramway between the city boundary and Aston Cross, and sanctioned a maximum speed of 10 miles an hour.

Ipswich.—The receipts on Monday amounted to £210, the number of passengers approximating to 52,500. The receipts on Sunday totalled about £110, making £320 in two days.

Belfast.—The notices which had been put on the order paper of the House of Commons of resolutions to refer the Corporation's Tramway Bill to a hybrid committee have been withdrawn.

Gosport.—Good progress is being made with the reconstruction of the tramway system, and the High-street section has been commenced It is expected that all the rails will be laid in two or three weeks' time

Halifax.—At the monthly meeting on Wednesday the Corporation were asked to authorise the laying of tramlines between Calder Bridge and the coal yard on the West Vale route, at an estimated cost of £1,762.

Hartlepool.—It is reported that, commencing on Monday last, the steam-driven trams of the North-Eastern Railway Company between Hartlepool and West Hartlepool have been entirely superseded by a new service of electric motor vehicles.

Accrington.—It is reported that the Corporation have submitted plans for the laying of a tramway along Market-street and Union-road, which scheme they propose to embody in the Tramway Bill they will submit for parliamentary sanction.

Waterloo and City Railway.—The directors recommend a dividend on the ordinary stock at the rate of 3 per cent. per annum for the half-year ended June 30, carrying forward a balance of £422. A year ago the dividend was at the rate of 3¼ per cent. per annum, with £170 forward.

Huddersfield-Halifax.—The Greetland District Council have received a letter from the solicitors to the promoters stating that the plans of the proposed system would soon be prepared, and that when running powers were obtained the scheme would be carried out expeditiously.

Birkenhead.—The year's working yielded an increase of some £3,600 in the receipts, the expenses being proportionately heavier. The gross profits amount to £21,198, and after appropriating £19,314 in respect of the debt, there remains a net profit of £1,883, which has been placed to the renewals fund.

Paisley.—The sections of the Paisley District Tramways Company's systems from the Cross to Potterhill (south) and to Johnstone (west) were inspected last week by Colonel Yorke on behalf of the Board of Trade. He was accompanied by members of the Paisley and Johnstone Town Councils and officials of the company. The inspection proved satisfactory.

Liverpool.—The Corporation tramways show an income during the past 12 months of £531,483, an increase on the previous year of £18,058. The total expenditure was £341,463, an increase of £1,652. After meeting charges for interest and sinking fund there remained a net surplus of £96,242, of which £64,000 was apportioned to reserve, renewal, and depreciation fund, and £32,000 to the relief of city rates.

South Shields.—The amended tender of the British Electric Traction Company was considered at a meeting of the Town Council on Wednesday. The new tender, upon which the Tramways Committee has resolved to base further negotiations, proposes to omit that portion of the authorised line between the termination of the present system at Tyne Dock and the end of Stanhope-road, and as an alternative the company agrees to apply at once for powers for the construction of a line from Bertram-street to the entrance of Tyne Dock, and in addition a line from Westoe to Harton. After a long discussion the matter was referred back to committee.

Digitized by Google

Stretford.—The Urban District Council Bill has passed the House of Commons Committee, and has been ordered for third reading, power being given to the Council to run a service of omnibuses as a connecting link between the Stretford and Withington tramways.

Stockport.—The Stockport and Hazel Grove Tramways Company, for the purchase of whose undertaking abortive negotiations took place lately with the Corporation, have made a profit for the last half-year of £630. 16s., which, with the £898. 4s. brought forward, permits of a dividend at the rate of 10 per cent., after carrying £891. forward.

Derby.—The opening of the first two sections of the Corporation tramways, alluded to in our issue of last week, was celebrated by a banquet given by the Mayor at the Derby Royal Hotel, which was attended by most of the councillors and officials. The toast given by the Mayor, "Success to the Undertaking," was received enthusiastically.

Bristol.—The Bristol Tramways (Extension) Bill, which has already passed the House of Lords, came before the Select Committee of the House of Commons on Unopposed Bills on the 28th ult., Mr. J. W. Lowther presiding. Mr. J. Clifton Robinson tendered evidence in support of the Bill. The Bill passed the committee, and was ordered to be reported to the House.

Gloucester.—It was reported at last week's meeting of the Corporation that the work at the Barton-street level crossing had been carried out to the satisfaction of the Midland Railway Company, and that the Board of Trade inspector would probably meet the railway officials on the spot in a few days, after which, if sanction were given, the cars would run over the crossing forthwith.

North Metropolitan Tramways Co.—The accounts of the company for the half-year ended June 30 last have been submitted to the Board, and, subject to final audit, the directors will recommend a dividend at the rate of 3½ per cent. per annum, carrying forward about £200 to next account. During the half-year the number of miles run were 6,943,973, and passengers carried 64,301,765.

London Traffic.—Mr. Stephen Sellon has been instructed by the Royal Commission on London Traffic to make a report upon the tramway undertakings in the principal cities and towns of the United Kingdom, and investigate the traffic and operative results obtained in connection therewith, and the conditions in regard to tramway transportation existing in such cities and towns as compared with London.

Railways and Electrification.—The report of the Barry Railway Company (South Wales) states that, as the result of the enquiry undertaken by the directors and officials into the question of electrification, in the course of which they investigated a detailed account of the working of electric railways on the Continent, the directors are of opinion that under present conditions the application of electrical power to railways which deal with a heavy mineral traffic is impracticable.

Southampton.—The tramway accounts for the year ending March 31 show a net profit of £6,206. The revenue amounted to £53,501, the total working expenses to £36,640, and interest and sinking fund charges to £10,654. The local rates will be relieved out of the profits to the extent of £5,000. The car miles run during the year amounted to 1,144,350, and the passengers numbered 9,890,952. The Town Council have decided upon extending the tramways by continuations of four existing lines.

Bath.—Good progress is being made with the repair of the tramway track. At the meeting of the Rural District Council last week there was an hostile expression of opinion in regard to the company's proposed loop line at Batheaston, to which the District Council have already refused consent, one councillor intimating that he should, if necessary, organise a petition against the project. The inhabitants, he stated, strongly objected to a double line. The Council have decided to communicate with the company representing that it would be desirable not to run the trams on Sunday before 1 p.m.

Exeter.—It is reported that there is considerable likelihood of a *modus vivendi* being arrived at between the Corporation and the Heavitree Urban Council in regard to an extension of the tramway system to Heavitree Park. As stated in a former issue, the Corporation stipulated that the Urban Council should first consent to the Corporation obtaining a provisional order for electric lighting in Heavitree, whilst the Urban Council stated that if the tramway system were constructed to their town they would then consider the question of the electric lighting order; and so the matter remained in abeyance. The Urban Council, however, are now desirous of reopening negotiations.

Swansea.—At its last week's meeting the Town Council again had before it a letter from the tramways company as to the approximate date when the Council would be prepared to pay the company the sum of £6,640, being the agreed price for the Morriston overhead electrical equipment. Eventually the following decision was arrived at: "That this Council will be prepared to take over the electrical equipment on the Morriston section on Oct. 1 next, and to let the same to the tramways company at a rental equivalent to interest, sinking fund, and depreciation on the sum paid until such a date as the Corporation are able to supply current to the tramways company."

Swindon.—The question of taking a *plébiscite* in regard to a proposal that the Corporation trams shall run on Sunday has been referred to committee. At last week's meeting of the Corporation a report was adopted with regard to the grant to be made by the Wilts County Council for the maintenance and repair of the main roads in the borough for the 12 months ending March 31, 1905, having regard to the disturbance caused to a considerable section of the main roads owing to the construction of the tramways, recommending that the County Council be informed that the Corporation will be prepared to enter into an agreement with the County Council for the payment by the County Council to the borough of the sum of £4,880 (being £240 less than the amount claimed by the Corporation) subject to its being clearly understood that this figure is for the current year only, and that in accepting this figure no question of principle such as might arise out of the construction of the tramways should be raised by the County Council.

Hythe-Sandgate.—The authorities at these towns are considering a project for an electric tramway between the two places. At a meeting of the General Purposes Committee of the Hythe Town Council last week, the question of an electric tramway service, upon which Mr. Sellon had been invited to report, was discussed. The following resolution was adopted: "That the Council are prepared to favourably entertain the promotion of a light railway order for a system of tramways between Hythe and Sandgate, and up the hill to the boundary near the Hotel Metropole, such order to be promoted in the ensuing session of Parliament by Mr. Sellon. Details as to road-widening, the routes, and other matters incidental thereto to be hereafter agreed to by the promotors and the Council."

Baker-street and Waterloo Railway.—Presiding at a meeting of the company on the 27th ult., Mr. Theodore J. Hare stated that all the tunnelling had been driven in the section between Waterloo and Melcombe-place. On the Elephant and Castle extension only 960 lineal yards of the main-line tunnel remain to be driven. One tunnel has now been driven right through from close by the Elephant and Castle Station site to the Marylebone Station of the Great Central Railway. At the depôt site the siding tunnel has been completed, and there only remain about 187 lineal yards of the branch line tunnel to be driven. On the extension of the company's line west of Baker-street possession has been obtained of the land for stations at Edgware-road and Lisson-grove, adjoining the Great Central terminus. The Edgware-road site has been cleared, and the shafts are about to be commenced. The up running tunnel has reached Lisson-grove, and the shield to enable the down running tunnel to be proceeded with is in course of erection, and will be finished shortly. The works generally are being pushed on as rapidly as possible, and the line is likely to be opened some time in the course of next year, though at present it is impossible to fix a precise date.

Aberavon.—At last week's meeting of the Town Council Mr. Lewis, of the firm of Messrs. Lewis and Fletcher, electrical engineers, Cardiff, attended on behalf of the syndicate which is promoting a scheme for the construction of an electric tramway from Briton Ferry to the sea beach at Aberavon. Mr. Lewis stated there would be a connection with the Neath trams at Briton Ferry, but the syndicate would not have running powers over the Neath lines. Two-thirds of the proposed line would be within the Aberavon area. It was not intended to run out Margam way, as it was not considered worth while. The main road along which the tramway would run could be lighted from the pillars of the electric system at a cheaper rate than the Council at present paid for gas. The Council would have the option of purchasing under the Tramways Act, and the promoters would also be prepared to offer other terms. The Council's provisional order expired last month, but had been renewed for 12 months. Mr. Lewis said the syndicate could not get their order until August of next year, and it would then take 18 months or so to complete the tramway. A resolution that the Council approve of the scheme, subject to satisfactory conditions, was carried unanimously, and it was arranged that Mr. Lewis should meet the Highway Committee to discuss terms.

Newcastle.—The annual report of Mr. Thomas Bowden, auditor to the Corporation, deals at some length with the question of depreciation. Alluding to the contention that the repayment of borrowed capital over the authorised term is a provision for depreciation, Mr. Bowden quotes the opinion of experts that the periods for which the loans have been obtained (permanent way 30 years, electrical equipment 20 years, cars 15 years) are considerably longer than the "life" of those assets, apart from the question of any exceptional renewals, and he emphasises the recommendation in his last year's report that the matter should receive serious consideration. It may be mentioned that in March of last year the tramways manager and the city engineer presented a report, in which they expressed the opinion that depreciation should be provided for by the investment and accumulation of £24,700 annually, in addition to the repayment of loans. At Wednesday's meeting of the Corporation a resolution was submitted that the consideration of the Tramway Committee's estimate of income and expenditure for the year ending March 25, 1905, be deferred, in order that the opinion of the town clerk, after consultation with counsel, if necessary, may be obtained as to whether the Newcastle Tramways Act of 1899 renders it compulsory to insert a definite sum in such estimates for depreciation.

Manchester.—An unusual accident occurred on the Heaton Park route last week. A few hundred yards from the park the roadway only permits of a single track. A bogie car returning from the park reached the loop, where the trams pass each other, before an advancing outward car of a smaller type had arrived at the points. Instead of waiting for the smaller car to get into the loop, the bogie car continued its progress, with the result that just as the other car was about to enter the loop the bogie car collided with it. The front of each car was knocked out of shape, and the windows were shattered into splinters. The cars recoiled with the impact, but remained on the rails. The passengers were precipitated from their seats, and some of them sustained severe cuts and bruises, while many of the female travellers naturally exhibited nervous symptoms. Both drivers appear to have escaped uninjured. The tramway officials on duty did everything possible to ensure prompt care for the injured, doctors being immediately telephoned for. An enquiry will be held into the collision in due course. It is stated that the driver of the bogie car asserts that the track was "greasy," and that the wheels skidded when he applied the brake. The Improvements Committee have adopted a proposal that a return be compiled showing the amount expended by the committee in connection with the tramways, the object being to demonstrate that the Tramways Committee, in showing large profits,

Digitized by Google

were largely indebted to the Improvement Committee for street widenings.

Colchester.—The opening ceremony of the Corporation tramways was performed, as intimated in our note of last week, on the 28th ult. The proceedings commenced with a reception at the town hall by the Mayor and Mayoress, and a luncheon given by the chairman of the Tramways Committee, the numerous company including several councillors, Mr. R. Sillar (the borough electrical engineer), Mr. R. C. Bullough (the tramways manager), Messrs. A. M. Conmett, Craufurd, and Tracey (representing Messrs. J. G. White and Co., the contractors), and Mr. H. Scholey (representing Messrs. Dick, Kerr, and Co., who supplied the cars). At this function compliments were interchanged between members of the Corporation and the contractors. A car containing several officials subsequently made a run to Lexden, the journey being performed quickly and smoothly. Later in the afternoon a five minutes' service was opened to the public, and was extensively patronised. The steep gradient of North-hill was easily surmounted by cars bearing the full legal complement of passengers. The total length of the line is 5 miles 1 furlong, of which 1 mile 7 furlongs is double. The contracts for the system, which is on the overhead principle, amounted to some £29,000 in the case of Messrs. White and Co., and to £16,298 in the case of Messrs. Dick, Kerr, and Co., making, with the cost of street widening, a total of about £55,000, which is well below the original estimate of £63,500. The cars are fitted with the Newell magnetic brake. The tramway receipts on Sunday amounted to £81. 10s. 3d. For Bank Holiday the receipts are estimated at nearly £120.

Brighton.—The tramcars are now running to the Brighton Central Railway Station. The opening of this latest addition to Brighton's system of tramway routes on the 27th ult. followed within a couple of hours on the official Board of Trade inspection made by Colonel von Donop. A car carrying the inspector, the Mayor (Alderman E. M. Marx), Alderman Stafford (chairman of the Tramways Committee), several members of the Corporation), and the tramways engineer (Mr. Holliday), ran smoothly to the top of Gloucester-road, where the double lines commence. The curve from Queen's-road into North-road was admirably negotiated. Then the car took the single rails to Gardner-street, where the double lines restart. Much interest was next evinced in the meeting of the new route with the old one at the bottom of North-road, where overhead there is quite a network of wires. The points here worked perfectly. The car then ran round the Pavilion terminus, circling the Victoria-gardens till the rails branched out from the up route to the station. Only a short distance of North-road was re-traversed, the car soon returning for the testing of other points on this "cross" system. Colonel von Donop expressed every satisfaction with the route, observing that he would have no hesitation in recommending the Board of Trade to grant the necessary certificate, on which assurance the route was opened the same evening. It is proposed to run a 10 minutes' service morning and evening, and a five minutes' service every afternoon. Both the Tramways Committee and the tramways engineer (Mr. Holliday) are to be congratulated on the rapid completion and the opening of the new route.

York.—It is reported that the question of the provision of electric tramways is likely to engage the attention of the city at no distant date. During the past year the City Council have insisted on the tramway company carrying out certain repairs to their permanent way, which has involved the company in considerable outlay; and it appears that the company have found the conditions imposed on them to be of an onerous and irksome character. The requirements of the Corporation have resulted in a letter from Mr. J. Kincaid, chairman of the York Tramways Company, which was read at a meeting of the Streets and Buildings Committee. The terms of the communication have not been disclosed, but it is understood that they may facilitate action by the Council in regard to taking over the system, substituting electric traction, and extending the system to other parts of the city. The further consideration of the matter was deferred to a special meeting of the committee to be held in September. The Corporation have the right to take over the lines by arrangement at any time by agreement, but they cannot promote a Bill to obtain compulsory powers within seven years of the promotion of the last Bill, February, 1902, when the proposal was defeated by a poll of the inhabitants. Since that time the company have proposed to extend the system from Blossom-street by way of Holgate-road to Acomb, but the Corporation refused to sanction the scheme. Public opinion in the city has, however, since undergone a decided change in favour of the acquisition of the tramways and the provision of electric traction, while it appears probable that the company would be quite prepared to sell. The extension of the Corporation power station has, it will be remembered, just been completed. It is stated, however, that there is little likelihood of the Corporation promoting a Bill in the next session of Parliament.

London United Tramways Co.—At the meeting of the Surrey County Council held last week, it was reported that Mr. Clifton Robinson had been interviewed as to the intentions of the London United Tramways, Limited, with reference to Hampton Court Bridge. Under the company's Act the tramway over this bridge is to be completed by the present month, but the company have applied for an extension of two years. It has been agreed that the County Councils of Surrey and Middlesex and the representatives of the company shall hold a conference in two or three months' time. In regard to Kingston Bridge, it is understood that the company desire also to exercise their powers of running over this bridge. The present width of the bridge is 25ft. Mr. Robinson submitted a scheme providing for a widening to 41ft. The two county surveyors reported upon the scheme, and recommended that the bridge should be widened to at least 50ft., and the Surrey County Council have adopted this view. With reference to Kew Bridge, the company have intimated their intention of promoting in the next session of Parliament another Bill for power to construct tramways over the bridge, a clause for this purpose contained in the Bill promoted by the company during the present session having been withdrawn. In the meantime the company are desirous of coming to terms with the two County Councils. The bridge, which was originally designed to be 45ft. wide, was ultimately constructed, at considerable extra cost, with a width of 55ft., so that there will be sufficient space for the tramways. The company are under an obligation, when electrifying the tramway between Kew Green and Richmond, to adopt some system which will obviate the use of overhead wires, and the County Councils consider that the same system should be used in the tramway over the bridge. Subject to this, an annual rental of £2,000 (£1,000 to each Council), and a few more conditions, the County Councils are prepared to consent to the scheme. On Monday some 300 cars carried 345,000 passengers, 107,000 going to Southall and Uxbridge, and 238,000 to Kew and Hampton Court. The whole of the traffic passed off without a hitch. Last year 315,000 passengers patronised the cars, but at that time the extension to Uxbridge was not opened.

Liverpool.—At Wednesday's meeting of the Corporation the question of applying for a provisional order to include the township of Fazakerley in the city area was down for discussion. The draft of the agreement with the Sefton Rural District Council (the authority for the Fazakerley district) provides, *inter alia*, that the Corporation shall within three years extend the electric tramway from the present terminus in Longmoor-lane to the Fazakerley station of the Lancashire and Yorkshire Railway. The report of the city engineer, the consulting electrical engineer, and the general manager on the permanent way, wheels, and overhead equipment of the tramways states that considerable benefit is expected to arise from the continuous welding of the rails. The life obtained from portions of the heaviest traffic lines had already exceeded the city engineer's original estimate, and it was probable that from such lines a life of 7½ to 10 years would be obtained. The durability both of the permanent way and of the car wheels depended on the relative suitability of the materials used and the care taken to maintain accurate adjustment not only of the rails, but of the rolling-stock. The cost of maintenance also depended very largely on the care taken by the drivers in approaching curves and crossings, and in the judicious use of brakes. As a result of experiments carried out for the last two years, a steel-tyred wheel was now being assembled and finished at Lambeth-road works which would cost 50 per cent. less than the price at which such wheels could at present be bought, and which it was believed would afford a life considerably in advance of the average of these wheels, which might be estimated at 60,000 miles, the average mileage of chilled wheels in Liverpool being 35,000. It was hoped that on trial this new wheel would be found suitable for general adoption. As to electrical equipment, the system adopted had proved satisfactory in work. The only alterations which it had been found advantageous to make had been in small matters of detail in some of the overhead fittings, by which the durability of these parts had been increased and replacement facilitated, with consequent reduction in the cost of maintenance. At the meeting of the Corporation Tramways Committee last Friday, it was reported that the traffic receipts for the past fortnight were £25,938. 19s. 10d., an increase over the corresponding fortnight last year of £4,423. 5s. 6d., attributable to the Royal visit. The passengers carried numbered 5,487,944, an increase of 865,992; the mileage was 493,725, increase 40,001 miles; cars running 462, increase 47. It was decided to continue the service on the Park-lane route for another three months, there having been a substantial improvement in the traffic on that route. The Traffic Subcommittee recommended that, having regard to the width of Edge-lane, a single line of tramway with passing places, and a double line where possible, be laid in Edge-lane, and that the necessary estimates be obtained by October in time for an application for powers to Parliament. An amendment that the recommendation be not confirmed was defeated by a large majority, and the proposal was adopted.

PROVISIONAL PATENTS, 1904.

JULY 25.

16393. A new or improved automatic electric cut-out switch. Emile Julien Javaux, 18, Buckingham-street, Strand London.

16395. An improved combined electric switch and lamp-holder. Charles Ernest Hunter, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

16396. Improved method of producing zinc from sulphate solutions by electrolysis. Charles Denton Abel, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Actien-Gesellschaft, Germany.) (Complete specification.)

16408. Improvements in and relating to electric circuit controllers, especially applicable in connection with the governing of elastic-fluid turbines. The British Thomson-Houston Company Limited, The Warwick Machinery Company, Limited, and Frederick Samuelson, 83, Cannon-street, London.

16409. Improvements in and relating to electric measuring instruments. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

16410. Improvements in and relating to electric measuring instruments. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

Digitized by Google

16411. Improvements in pneumatically-operated signalling devices. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

16418. Improvements in electrically-driven winding engines. Anton Raky, 77, Chancery-lane, London.

16422. Improvements in the manufacture of electrical resistances. Electric Equipment and Securities, Limited, and Charles Ruzicka, Clun House, Surrey-street, Strand, London.

16423. Improvements in the manufacture of electrical resistances. Electric Equipment and Securities, Limited, and Charles Ruzicka, Clun House, Surrey-street, Strand, London.

16424. Improvements in the manufacture of electrical resistances. Electric Equipment and Securities, Limited, and Charles Ruzicka, Clun House, Surrey-street, Strand, London.

16425. Improvements in the manufacture of electric incandescence bodies. Electric Equipment and Securities, Limited, and Charles Ruzicka, Clun House, Surrey-street, Strand, London.

16426. Improvements in and relating to contact breakers for induction coils. Frederick Rowland Butt and Harry William Charles Cox, 70, Chancery-lane, London.

16447. Improvements in electric switches for use in pole changing. James Yate Johnson, 47, Lincoln's-inn-fields, London. (Voight and Haeffner Aktien-Gesellschaft, Germany.)

JULY 26.

16461. An improved electric locomotive. David Liddell Crawford, 26, Queen-street, Dunoon, Scotland.

16479. Improvements in telephone repeaters. George Washington Kretzinger, 46, Lincoln's-inn-fields, London. (Complete specification.)

16483. Improvements in or connected with electric arc lamps. James Brockie, 33, Chancery-lane, London.

16489. Improvements in or relating to apparatus for controlling electric ignition currents of internal-combustion engines. Humber, Limited, and Samuel Henry Halford, 111, Hatton-garden, London.

16509. Improvements in telephone directories. Frederick Drowns, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Jan. 29, 1904, being date of application in United States.) (Complete specification.)

JULY 27.

16573. Improvements in Morse telegraph transmitters or instruments for transmitting telegrams by means of Morse signals. Richard Wolters, 37, Essex-street, Strand, London. (Complete specification.)

16579. Improvements in incandescent electric lamps. Richard Aloysius Gill, 6, Lord-street, Liverpool.

16581. Improvements in electrical binding screws or terminals. Maurice Bouchet, 53, Chancery-lane, London. (Date applied for under Patents Act, 1901, Feb. 15, 1904, being date of application in France. (Complete specification.)

16595. Improvements in and relating to supporting devices for electric fans. Sidney George Leach and Edward Bergtheil, 1, Queen Victoria-street, London.

16601. Improvements in telephone central-station systems. Gustaf Lambert, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Aug. 18, 1904.

1903.

14172. Systems of electrical distribution. Le Tall. (Cooper Hewitt Electric Company.)

17662. Electric lighting of trains. Hill.

17871. Electric arc lamps known as flame arc lamps. Oliver.

20137. Electric arc lamps. Ewart.

20522. Electric switches. Eckstein and Krause.

20620. Dynamo-electric machines. Chitty.

23192. Dynamo-electric generators and motors. Jones and Jandus Arc Lamp and Electric Company, Limited.

25905. "Frog" or plate for making connections between the ends of line wires, at junctions, or crossovers, or any place where the line is not continuous in conductors used in overhead wiring for electric tramcars and the like vehicles. Perkins and Massey.

26811. Multiplex telephony. Fairweather. (Miner.)

1904.

9236. Continuous-burning arc lamp with amalgam electrodes. Hoffmann.

9914. Magneto-electric igniting device. Hauptmann.

10618. Device for winding up clocks automatically by means of an electric motor. Barile.

10906. Apparatus for electrically stopping railway trains. Lichtenfels.

11272. Electrical safety apparatus for signalling on railways. Mackenzie. (Soc. Cousin and Co.)

14026. Electrostatic apparatus for measuring electrical potential differences. Marchant and Worrall.

14231. Electric sparking plugs for internal-combustion motors. La Force. (Date applied for under International Convention, June 24, 1903.)

14545. Thermo-electric couples or apparatus. Bristol.

NOTES.

Electric Railway Accidents.—Mr. R. Bell, M.P., the general secretary of the A.S.R.S., has again officially approached the Board of Trade with a view to compelling the railway companies to adopt some protection for the newly-electrified railways.

Lucknow Tramways and Lighting.—The concession for the building of the tramway system for Lucknow and also for the supply of electric light and power has been obtained by Messrs. Kincaid, Waller, Manville, and Dawson. We understand that the terms offered by the Municipal Board have been substantially accepted by this firm. The larger portion of the scheme is the tramway undertaking, but there is no doubt that a considerable demand will arise for light and power.

Electricity in Railway Carriages.—We understand that the Great Northern Railway Company are now equipping, at their Doncaster works, a number of the luxurious dining cars used on the East Coast Scotch expresses with electric lights, fans, etc. This step has doubtless been taken so that the East Coast Scotch trains may, in this respect, conform with those of the rival routes, the latest types of coaching stock of both of which were some time ago equipped with electric illuminating apparatus.

Wireless Telegraphy Control in the States.—President Roosevelt has approved the report of the Evans Commission, awarding the control of the Government's coastal system of wireless telegraphy to the Navy Department, on the ground that it is part of the country's defence, and of more importance to the navy than to the army, with the exception of the stations necessary for communication between army posts. The report recommends legislation to prevent private companies from interfering with the Government's coastal system of wireless telegraphy.

Personal.—We are informed that Mr. W. B. Esson, having held the position of manager of Messrs. Johnson and Phillips's Electric Light and Power Works for the past 10 years, retires from Charlton at the end of the present month. During the above period many large and important contracts have been carried out by the firm at home and abroad, for all the designing in connection with which Mr. Esson has been responsible. We trust that Mr. Esson's technical knowledge will still be applied to the advancement of the profession.

British Science Guild.—The committee engaged in organising an institution under this title are circulating a memorandum in all parts of the Empire amongst those likely to be of assistance in conducting the scheme, inviting their co-operation in promoting the objects of the movement, the chief of which is to secure the application of scientific methods to every branch of the affairs of the nation by means of conferences, lectures, publications, etc. The active supporters of the scheme include a number of influential names in scientific circles. All British subjects, men or women, are eligible for membership of the guild, the subscription to which will be of a nominal character.

Electric Traction in Sweden.—The Swedish Government is, says the *Scientific American*, thinking seriously of using electric traction on the State railroads, the current to be obtained from the numerous waterfalls which are found in that country. To this end Parliament has been asked to vote a large grant for the transformation of the system. Preliminary trials are to be carried out on a section of the Varta railroad, also on a portion of the line running from Stockholm to Jarfra. The current for this purpose will be furnished by the Stockholm central station and from a temporary plant which is to be installed at Tomteboda. Four large electrical firms have already submitted plans for the trial of their systems—the Siemens-Schuckert, Allgemeine, Oerlikon, and British Westinghouse Companies.

Telephone Sketching Chart.—We have received from Messrs. W. T. Glover and Co. an interesting sketching chart to be used in connection with telephonic communication, which will be of great service when ordering special work in a hurry. The idea of the chart is that both the sender and receiver shall have before him a piece of squared paper with the ordinates and abscissæ numbered to correspond. On this chart at the sending end there is sketched the article which is required. The sender then instructs the engineer at the receiving end of the line to draw lines from point to point on the squared paper until the drawing is complete. The idea has been worked out by the manager at Messrs. Glover and Co.'s works, and we can quite see that in certain cases it will be of very great value to engineers. A boy could take down the instructions as to drawing, which could then be handed over to a draughtsman to prepare on the receiving chart. These charts are being supplied free to the friends of Messrs. Glover and Co., and seem likely to come into general use.

Open Arc Lamps and Ice.—Mr. W. A. Thomas, of the Abingdon Electric Company, Illinois, communicates to *Electricity* of New York a "wrinkle" for obviating the difficulty encountered in street-lighting when sleet and ice are prevalent. Mr. Thomas's company use open arc lamps for this purpose, and during the earlier part of last winter, which was a very severe one, great trouble was experienced from these sources. Whenever the carbons started to coat with ice, pieces of rather stiff manilla paper, about 4in. square, folded cone shaped, were placed, after removing the ice from the ends of the carbons, above the top of the lower carbon and fastened in place with a small piece of magnet wire. This makes a complete break between the carbons and prevents the ice from forming on the upper end of the lower carbon. When the current is turned on the paper burns out, and the lamp is seen to be unaffected by the ice. As the result of this experiment the problem was solved so satisfactorily that the company were relieved from all further trouble, while neighbouring plants were unable to run.

Electrical Standards.—Elsewhere in this issue will be found in full the interim report of the Engineering Standards Committee on the question of the use of standards for electrical machinery. This report reached us too late for comment this week, as it deals with such a wide range of subjects. It will be gathered, however, from the introduction that the sub-committee appointed for the purpose have gone most carefully into the matter, and have had done for them a considerable amount of original work, which renders their decision more valuable. We are sure that all interested in the electrical profession will do their best to adhere to the standards now fixed. The fact that the Admiralty, the War Office, the Crown Agents for the Colonies, and the National Physical Laboratory were all represented on this committee is worthy of special note. The first three departments are large purchasers of plant, and their custom alone will do much to secure the adoption of standard electrical machinery. It will be of great assistance to English manufacturers if the number of types of machines they are called upon to supply can be reduced to those included in the committee's schedule.

Faraday House.—We have received a copy of the August issue of the *Faraday House Journal*. The articles from students and old students include papers upon "The Theoretical Consideration of the Steam-Turbine," by H. W.

Digitized by Google

Swann; "The Advisability of Earthing the Middle Wire in Three-Wire Installations," by D. M. Hutchison; "The Method of Reducing the Pressure Drop in Rails of Electric Tramway Systems," by A. Murray Coombs, and upon "Electricity in Use in Gold Mining," by G. M. Dyott. It also contains an interesting article upon the Reading Electric Supply Company, which is affiliated to the institution. The opening paragraphs deal with the appointments obtained by former students, and also refer to the new establishment which is being erected in Southampton-row, which will afford about twice the accommodation provided by the existing premises. The journal also contains notes from a number of affiliated companies connected with this institution, covering a great variety of work in electrical and mechanical engineering. It is evident that this institution, which was the first to combine instruction in scientific knowledge with practical engineering training, has met with considerable success.

Discrimination of the Demand upon Individual Transformers.—The *Western Electrician* of Chicago gives an account of a simple method for the determination of the demand upon individual transformers, which was described by Mr. G. S. Haley at the last meeting of the National Electric Light Association. Mr. Haley states that the easiest way to determine the demand is to measure the primary current passing through the transformer. The author used the insulator-type primary cut out supplied by the General Electric Company. A duplicate plug was made of hardwood, with an extended handle 6in. long and 2in. in diameter. Two of the brass clips from an old plug were placed upon the wooden one, and through two holes in the handle two No. 6 rubber-covered cables were connected to the clips, the cables being about 8ft. long and connected to a 30-ampere Wright discount ammeter mounted upon a board about 8in. by 12in. Upon the back of the board are two pieces of wrought iron of suitable size to hook over an ordinary cross-arm. To test the transformer it is only necessary to place the ammeter upon a convenient cross-arm, pull out the plug in one of the transformer cut-outs, and insert it at the end of the cables. Mr. Haley states that he usually leaves the plug in service for two nights, and then removes it to some other transformer.

Wireless Telegraphy and Meteorology.—It will be remembered that a few weeks back the committee appointed to consider the working of the Meteorological Office recommended that wireless telegraphy should be experimented with for obtaining advance news of atmospheric conditions in the Atlantic. Pending the adoption of this suggestion officially, the *Daily Telegraph* has arranged with the Marconi Company and the Atlantic steamship companies for a temporary service, the vessels to transmit messages as soon as they come within range of the signalling stations. The distance from which the vessels can transmit messages to the land is at present limited to about 100 miles, but the messages will report not only the weather conditions at the moment of dispatch, but those of the previous days, during each of which the vessel may have travelled 400 or 500 miles. This excellent idea was inaugurated at the end of last week, three messages received from the "Tunisian" appearing in Saturday's issue of the *Telegraph*. Greatly improved apparatus is being devised for the vessels—and will be installed on the new Cunarders—with a view to the transmission of messages from mid-Atlantic, so that practically the whole area of the ocean west of Ireland—so momentous to the meteorology of this country—may be under observation. It is somewhat early yet to speak of the efficacy of the system, especially considering its present limited scope, but one can see that it may prove invaluable in heralding the approach of storms.

American Institute.—We have received a copy of the *Transactions* of the American Institute for June, which contains the discussions on the following papers: "Theory of the Regulation of Alternators," "The Mechanical Construction of Revolving-Field Alternators," "European Practice in the Construction and Operation of High-Pressure Transmission Lines and Insulators," "The Conductivity of the Atmosphere at High Voltages," "The Relative Fire Risk of Oil and Air Blast Transformers," "Group Switches in Large Power Plants," "Oil Switches for High Pressures," "Terminals and Bushings for High-Pressure Transmission." A summary of the proceedings at the annual meeting is given, with abstracts of the following papers read on that occasion, and of the discussions thereon: "Predetermination of Sparking in Direct-Current Machines," by W. L. Walters; "Effect of Self-Induction on Railway Motor Commutation," by E. H. Sanderson; "The Calculation of Line Batteries," by W. E. Winship; "Data and Tests on a 10,000-cycle-per-second Alternator," by G. B. G. Lamme; "Notes on Flywheels," by H. H. Barnes, jun.; "The Single-Phase Induction Motor," by W. S. Franklin; and "Wave-Form Variations on a Long-Distance Line," by G. H. Rowe. There is also a paper on the "Operation of Synchronous Converters," by S. C. Lindsay.

Electrical Machinery for Panama.—Mr. G. E. Walsh, in the *Electrical Review* of New York, prophesies that there will be some splendid contracts for electrical manufacturing firms in connection with the completion of the Panama Canal. He assumes—and we are afraid he is correct in his assumption—that only American firms will have a chance to get this work. In the earlier history of the enterprise, when French engineers were responsible for the work which ended so disastrously, English firms had a good share of the contracts, and we think that even now they should be allowed to compete. Of course, if protective duties in favour of American firms are enforced, it will be a waste of time to attempt to secure contracts for this country. Mr. Walsh adds that electricity will play a large part in the excavation and equipment of the canal, and that there will be hardly a machine, repair shop, or operating plant which will not have electric power in some portion of it. He further states that within six months the designs and specifications for the first part of the machinery will be completed, and that the delivery of certain machinery may even be required this year or in the early part of next. After considering the local conditions, he is inclined to favour oil as the cheapest fuel, owing to the high cost of transporting coal or wood to the sites where power will be required. The article concludes with a prediction that the American plant used in the construction of this canal will do much to secure for the United States the electrical orders from South and Central America which heretofore have come to England or Germany. May he prove a false prophet!

The Operation of Textile Mills Electrically.—An address was delivered by Mr. S. B. Paine to the members of the British Association of Managers of Textile Mills at Manchester on Tuesday, the subject being "Electrical Centralisation of Power: The Operation of Textile Mills from a Central Power Station." Mr. Paine said that in the United States the electric drive in textile mills had passed the point where its utility and advantages could be questioned. Its many points of superiority were very generally admitted. The advantages of the electric system included greater reliability and facility for enlargement or rearrangement. The cost of power was

Digitized by Google

generally the first objection raised to the purchase of current. It was assumed that the station could not compete with the mill in that respect. That, however, Mr. Paine contended, did not follow necessarily—in fact, the reverse should be true. Wherever the electric drive had been used, he said, by manufacturers who had previously used the mechanical system, they had, without exception, remarked upon the steady and uniform speed which resulted. That steady speed must tend to greater production, improved quality, and less repairs to the machinery. In the present age of competition, the provision of a central power station freed the manufacturer from the consideration of all questions connected with the generation of power, and to that extent enabled him to devote his energies more efficiently to his business. If he purchased his power from a central station, fluctuations in the price of coal and kindred questions caused him no anxiety. Mr. Paine expressed the view that there should be but one power plant in each community, local conditions determining whether that power plant should be owned by the mill or by the central station. A discussion followed the reading of the paper.

British Association.—In our last week's issue we outlined the general programme of the meeting to be inaugurated at Cambridge on the 17th inst., and we now give the provisional programme of the branch devoted to engineering—Section G: Thursday, Aug. 18—11.30 a.m., address by the Hon. C. A. Parsons, president of the section; 2 p.m., lecture by Mrs. Ayrton, "The Origin of Sand Ripples." Friday, Aug. 19—Mr. C. Dugald Clerk, "Flame Temperatures in Internal-Combustion Motors"; Prof. B. Hopkinson, "Some Tests on a Small Gas-Engine" (to be followed by a general discussion). Monday, Aug. 22—Mr. C. H. Merz, "The Use of Electricity on the North-Eastern Railway and on Tyneside"; Mr. A. A. C. Swinton, "Electricity from Water Power"; Mr. W. M. Mordey and Mr. A. G. Hansard, "Energy Losses in Magnetising Iron"; Prof. J. A. Fleming, "Large-Bulb Incandescent Lamps as Secondary Standards of Light"; Mr. Clifford Paterson, "Investigations of the Harcourt Pentane Lamp." Tuesday, Aug. 23—Major Sir Hanbury Brown, K.C.M.G., "The Control of the Nile"; Mr. J. H. Wicksteed, "A Universal Testing Machine of 300 tons for Full-Sized Members of Structures"; Mr. S. Cowper Coles, "A New Process for the Protection of Iron and Steel from Corrosion"; Mr. J. W. Hayward, "The Effects of Receiver Drop in a Compound Engine." Other papers: Dr. W. E. Sumpner and Mr. R. W. Weekes, "The Hopkinson Method applied to Induction Motors"; Mr. Killingworth Hedges, "The Action of Lightning Strokes on Buildings"; Prof. E. Wilson, "The Electrical Conductivity of certain Aluminium Alloys as affected by Exposure to London Atmosphere, and a Note on their Microstructure"; Mr. A. H. Peake, "Superheated Steam: throttling and other experiments"; Prof. J. O. Arnold, "The Effect of Rapidly Alternating Stresses on Structural Steels."

Electricity in Coal Mines.—A paper on electricity as a motive force in the working of collieries was presented on Tuesday to the members of the Manchester Geological and Mining Society by Mr. Philip C. Pope and Mr. Norman D. Cameron. Colonel Hollingworth presided. The title of the paper was "On Practical Comparisons of Direct-Current and Polyphase Systems as applied to British Collieries." The authors put aside the question of the suitability of electricity as a means of transmitting power about a colliery. That was a well-worn subject, they said, which had been thrashed out many times over, and on the whole they believed that the balance of decisions was in favour of the newer power agent. It was rather their purpose to elicit such a discussion as would be likely to assist a colliery manager who had already decided to adopt electrically-driven machinery, in settling which of the two electrical systems he should employ at his own pit. A few years ago there was only one practicable system for use in a mine—continuous current—but more recently electrical engineers had brought the three-phase alternating-current system to such a state of perfection that its practical utility could no longer be questioned. That it was thoroughly reliable and practically economical was amply demonstrated by the fact that the large power supply companies had decided without exception to generate three-phase current only. In deciding which system to adopt at a colliery, one must consider their relative advantages under three main heads: first, which would give the greatest freedom from breakdowns, and consequently the maximum economy in maintenance expenses; secondly, which would be most efficient in transmission, distribution, and transformation of energy; and, thirdly, which was cheapest to instal, given equally good material and workmanship in each case. All these points were considered, and the conclusion was in favour of the three-phase alternating-current system. The paper will be discussed at a later meeting.

Earth Shields in Transformers.—In one of the papers read before the American Institute of Electrical Engineers at its June meeting in Chicago by Mr. J. S. Peck, the advantages and disadvantages of ground shields in transformers is discussed. The general conclusion of the paper is that in all transformers to some extent, and particularly in large transformers, the grounded conducting shield between the primary and secondary windings does not convey adequate protection without marked additional expense. It is suggested that a cheaper and better substitute for the ground shield is a grounded secondary circuit. The above conclusions appear very sound. It is not as though the ground shield within the transformer dispensed with the inconvenience and expense of establishing a reliable ground connection on customers' premises. Whether a grounded shield or a grounded secondary circuit is used, the ground has to be made near the transformer on installation. If the ground wire is properly connected to the secondary circuit, a permanent and reliable protection for the latter should be secured. If, in order to secure insulation for the secondary circuit, a grounded shield is interposed, extra insulation must be used and valuable space sacrificed to the detriment of the transformer's behaviour. From every standpoint a permanently grounded secondary circuit seems preferable. Moreover, as the paper points out, even if the ground shield may be regarded as forming a perfectly reliable safeguard against accidental crosses between the primary and secondary circuits within the transformer, it is powerless to protect against crosses between the primary and secondary circuits occurring in the leads emerging from the transformer, or in the neighbouring wiring. There can be no doubt, however, that the proper point at which to ground a secondary circuit is the neutral point of the transformer secondary winding. We are indebted to the *Electrical World* for the above interesting summary of Mr. Peck's paper.

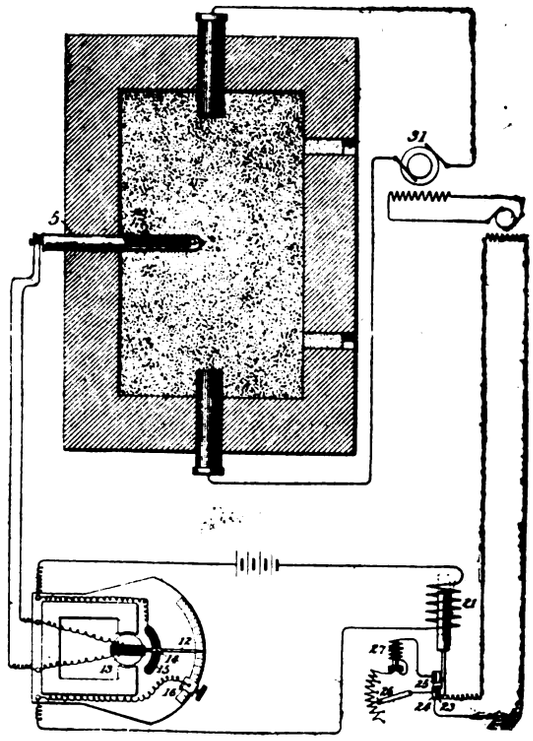
Worship by Telephone.—Another example of the Protean uses of electricity is given in the *American Telephone Journal*. It occurred to a well-known Philadelphian pastor, whose daughter was confined to her room by illness, that, as the telephone had been employed for such a variety of purposes, it might be utilised for transmitting a sermon or a hymn to a distant audience. Accordingly, a megaphone fitted with a telephone connection was placed in the church, which possesses favourable acoustic qualities, and the patient was enabled to follow the entire course of the sermon and to hear the hymns distinctly. This result

Digitized by Google

encouraged the cleric to carry out the idea on a larger scale, and half a dozen megaphones were suspended in front of the pulpit, enabling the service to be transmitted to a hospital in the city. For those too weak to hold the receiver head attachments were provided. The experiment was so successful that other hospitals are reported to be arranging for similar telephonic connection. It appears that this innovation is not unique, for, curiously enough, an idea of the like nature was put into practice almost at the same time in Texas, though in this case the absent votaries were not invalids, but "stay-at-homes." The Citizen's Telephonic Company of that State have installed a telephonic connection at a Presbyterian church, such members of which as subscribe to the company being now able to perform their devotions at home. The idea is attributed to the manager of the telephone company, who claims to have projected it for some years. This new mode of worship prompts our contemporary to advance an observation which seems to offer a way out of the "empty church" problem. The suggestion is a no less sweeping one than the church—*i.e.*, the church building—should be dispensed with altogether. Thus: "One might almost fancy that if the idea should be extended much farther, the entire necessity for a church building would be obviated, and that the congregation could follow their rector, and even join in chorus singing, in the privacy of their homes, while the pastor sat talking into a large megaphone in the retirement of his study." As our contemporary adds, that the "congregation" would be able to select their favourite preacher or to change from one sermon to another.

Electrical Progress in Italy.—A recent report by Mr. A. P. Bennett, commercial attaché to the British Embassy at Rome, refers at some length to the remarkable increase in the utilisation of electric power in Italy since 1890. At the present time a total motive force of over 200,000 h.p. is provided in that country electrically, while in 1890 it is improbable that the total electrical energy available exceeded 20,000 h.p. Milan alone disposes of 20,000 h.p., and the large new hydro-electric station at Vizzola, near Milan, distributes 18,000 h.p. to various points in the provinces of Milan and Como. Other stations of importance in Lombardy are those of Calvagese, Varese, and Campodolcino. In Piedmont four plants belonging to the Societa Alta Italia were erected between 1890 and 1901 at Lanzo, Bussoleno, Stambinello, and Germagnano, generating a total force of 12,000 h.p. Other important plants erected since 1890 are those of Cossogno, in the province of Novara, and of the Company Casalese, in the province of Alessandria. Further, in Lombardy and Piedmont, especially in the provinces of Turin, Novara, Bergamo, Brescia, and Como, numerous plants have been erected, which distribute a total motive force of over 5,000 h.p. The central station at Genoa generates and distributes over 8,000 h.p., and those of Rome and Naples over 10,000 h.p. respectively. The new plant at Celina will shortly be in a position to distribute a motive force of about 18,000 h.p. to the provinces of Udine, Treviso, and Venice. In Umbria there are two big plants utilised by local factories distributing over 15,000 h.p. In 1890 electric traction was only utilised on the Florence-Fiesole line; to-day, in addition to the complete urban and suburban lines at Milan, Naples, Rome, Genoa, Florence, Leghorn, Palermo, Perugia, and Varese, there are the electric lines of Milan-Monza, Milan-Callarate-Varese, Lecce-Colico, Terni-Collestatte, Lecce-San Cataldo, and some few lines on the Italian Riviera. In the aggregate there are some 320 miles of railway in Italy served by electricity. In 1890 there were about 400 communes in Italy either partially or totally lighted by electricity. To-day electric light is general in at least 600 communes. The development of electricity for industrial purposes in Italy has been very marked, and the water power with which the country is so richly provided offers scope for still greater progress.

Temperature Control of Furnaces.—A patent has been granted in the United States to Mr. W. McA. Johnson relating to a method of controlling the temperature in an electric furnace, of which a description is given in the *Electrical World* of New York. We reproduce a diagram showing a furnace of the resistance type, the energy being supplied from dynamo, 31, to two electrodes. Inserted in the furnace is the pyrometer, 5, of the Le Chatelier type, connected to a galvanometer with a movable coil, 13, the needle, 12, indicating on a graduated scale the temperature within the furnace. This needle is made of platinum, and is insulated from the movable coil, 13. It is provided with the metallic contact, 14, which dips into mercury, 15. The second contact, 16, which is also made of platinum, is secured to a movable block, which is placed on that point



of the galvanometer scale which corresponds to or slightly exceeds the temperature desired in the furnace. As the furnace temperature rises to this degree, the needle, 12, makes contact with the point, 16, thereby completing a circuit in which is inserted a battery and a solenoid, 21, which attracts a soft iron core, shifting the contact, 23, from 24 to 25, thereby introducing into the field of the exciter the variable resistance, 26, and the electromagnetic cut-out, 27. These devices are so constructed and adjusted that the electromagnetic cut-out will break the circuit only in case the resistance proves insufficient to reduce quickly the furnace temperature.

Live-Wire Testing Devices.—The *Western Electrician* of Chicago describes some apparatus for determining whether current is flowing in a cable, which apparatus is designed for use on alternating-current lines, but has also been found satisfactory for direct-current work, provided the current is supplied from a generator. The apparatus, which is manufactured by the Minerallac Company of Chicago, consists of a telephone receiver and a small current transformer with a hinged core. The secondary wiring of the transformer is connected to the telephone

Digitized by Google

receiver, and the hinged core is clamped around or against the cable to be tested, the cable forming the primary of the transformer. This device will be found very sensitive. We reproduce two diagrams illustrating an electroscope designed to afford a simple means of determining the presence of a dangerous potential in an electrical conductor. The device consists of a glass tube, in which is hermetically sealed a copper plate carrying an indicating leaf similar to that in the ordinary gold-leaf electroscope In using, the

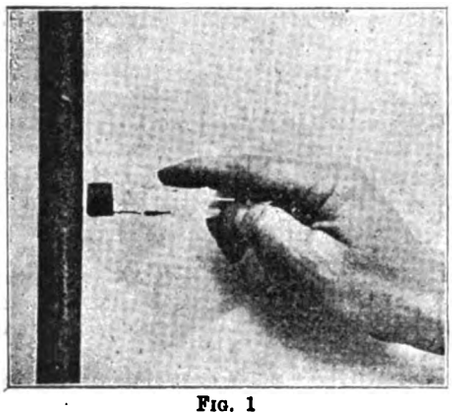


FIG. 1

end of the electroscope is held in close proximity to the conductor to be tested. It will indicate positively all potentials in excess of 500 volts. If the conductor is "dead," the indicating leaf will remain flat (as in Fig. 1). If the conductor is "alive," the indicating leaf will tend to take a position at right angles to the tube (as in Fig. 2).

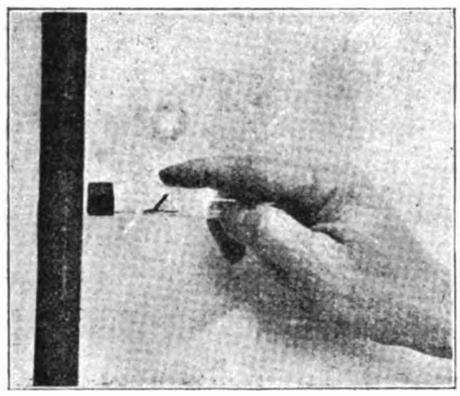

FIG. 2.

It will not, however, work on a grounded conductor, or a conductor surrounded with a lead sheath.

Baltimore and Ohio Third-Rail System.—About a year ago we referred to the sectional third-rail system installed on the Baltimore and Ohio line. The locomotive used on this system has recently been improved by an alteration in the collecting device. It will be remembered that the sections of the third-rail only became alive when the locomotive was over them. The system employed was that of a Hopkinson switch, using a high-voltage pick-up coil and a series holding-up coil. There has evidently been a certain amount of trouble with this arrangement, owing to the failure of the high-voltage supply, or to the reduction in pressure when heavy loads are on. In consequence of this a small dynamo driven by compressed air has now been added to the car, to energise the high-voltage pick-up coil The *Street Railway Journal* of New York illustrates this new apparatus, the air motor being a reversed air compressor. It is controlled by means of the arrangement shown in Fig. 1, and operates as follows: Assume the engine to be resting on a third rail, which is disconnected from the power-house or dead; that the tanks are full of air, and that the compressor also is at rest. Air is admitted to the compressor, and the magnet, E, being de-energised, the valve is at once shifted to engine position, the machine starts as an armature, and rapidly builds its dynamo up to voltage. The circuit connecting the compressor to the electric line is then closed. As the air pressure reduces, due to the demands of the compressor upon the tank, the pump governor closes its circuit also. This completes a circuit of the compressor from third rail to ground, and raises the potential of the third rail to 550 volts, and immediately picks up the sectional track switch. As soon as this occurs, current from the third rail enters the compressor system and proceeds to drive the machine as a motor. The magnet, with its additional excitation, now readjusts its sliding valve, and the valve shaft now moves to compressor position, and the machine now compresses air. This it continues to do until the tanks have been pumped up to 90lb., or to whatever pressure the pump governor is set. At this instant the

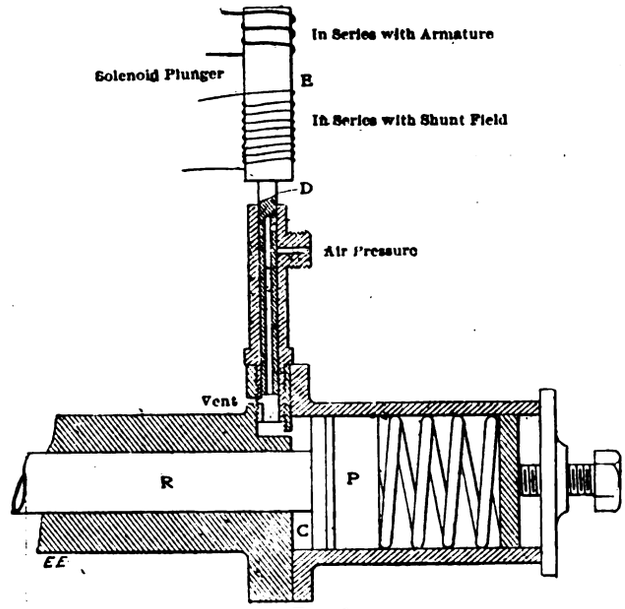

FIG. 1.

pneumatic governor flies open, the sliding valve drops, and the machine becomes an engine, and runs as such for a brief period until the cycle of operation is repeated. If the locomotive is running, the sectional track switch will, of course, not drop, for it is held up by the locomotive current in the series coil, but this will make no difference in the behaviour of the compressor, whether it be on a permanently live or on a sectional rail. When the locomotive is drifting over sections it is highly important that the current shall always be available to the motorman; therefore, the sectional switch must be kept up, and for this purpose the compressor is sufficient. If for any reason the switch should happen to drop, due to jar, it will instantly pick up again, because the compressor keeps the rail at a voltage equivalent to that of the line. In order to control the compressor from the motorman's stand, it is necessary that he have complete control of both the air supply and the electric supply. The latter is easily provided for by means of a switch at his station. The air supply, however, is controlled electro-pneumatically. An automatic air-valve is placed on the tank. On the right and left of this air-valve are two bobbins, which open needle valves which control a piston which operates a main valve. The needle valves are controlled by a dry battery, operated by two buttons at the motorman's stand, one of which will open and the other close the main valve. If the motor is resting on a dead section, and the motorman desires to start, he presses the starting button. This brings the compressor to rest, having cut off both of its sources of energy, and leaves him with air in the tank for starting purposes again.

THE DERBY ELECTRIC TRAMWAYS AND ELECTRICITY SUPPLY.

This week, through the courtesy of Mr. T. P. Wilmshurst, we have had an opportunity of looking through the whole of the electrical work at Derby which is under his control. We had hoped to do so during the meeting of the

MR. T P. WILMSHURST, BOROUGH ELECTRICAL ENGINEER, DERBY.

Incorporated Municipal Electrical Association, of which Mr. Wilmshurst was president. The exceedingly full programme, however, prevented this, and we deferred our visit until now, when the first two sections of the tramways are opened and at work. It was in February, 1893, that we last went through the Derby electricity works, which had then commenced supplying only a few months. We were interested, therefore, in seeing what proportion of

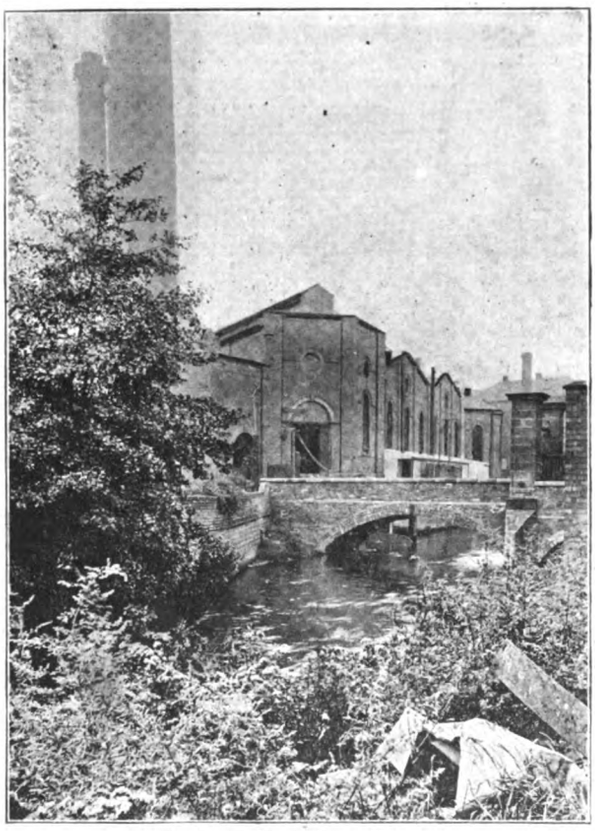

FIG. 1.—The Derby Power House.

the plant then installed is still in use. The first station might well be compared to an amphitheatre, the switchboard platform serving as raised seats for the spectators. The engine-room floor was then somewhat like an amphitheatre in plan, and it was covered with a variety of small units, which were of three different types. The basement, with its one point of ingress and egress, was like a prison, where steam and oil were applied to the unfortunate staff responsible for the steam-pipe joints. Amongst the plant there were the alternators directly coupled to their steam-engines. These were of the Siemens type, and they had the low frequency of 40 complete cycles per second. The exciters were also steam driven, and the arc lighting dynamos, again, had separate steam-engines to drive them. These arc-lighting dynamos were of the continuous-constant-current type made by Messrs. Siemens Bros., and the current was kept at a uniform value by means of brush rocking gear, which varied the point of collection on the commutator. These machines, which were then of a new type, have done remarkable service, and they are the sole survivors of the generating plant we saw in 1893. For economical reasons they are shortly to be replaced, and hence we have pleasure in illustrating in Fig. 2 one of these interesting dynamos.

In Fig. 3 we show the plan of the station as it now is with the new machinery in position. The extreme left-hand corner is the original site, and it has since been extended by the addition of a new boiler-house and the triangular engine-room, which now contains two out of the three Parsons turbo-alternators of 300 kw. each, two of the three 700-kw. Ferranti sets, and the two 150-kw. Siemens-Browett-Lindley sets. Even now the faults in design of the old station hamper progress to a certain extent, but under Mr. Wilmshurst's able supervision this is likely to be corrected in the future. The Corporation have obtained a large new site on the other side of Silk Mill-lane, which has nearly three times the superficial area of the present central station. When this site has been cleared there will be ample space for thoroughly up-to-date works, equipped on the most economical lines with direct-current machinery. At present the only building which has been put on the site is the accumulator house, one floor of which we illustrate in Fig. 4. In this there are two batteries of the Chloride Company's make, one being used for lighting and one for

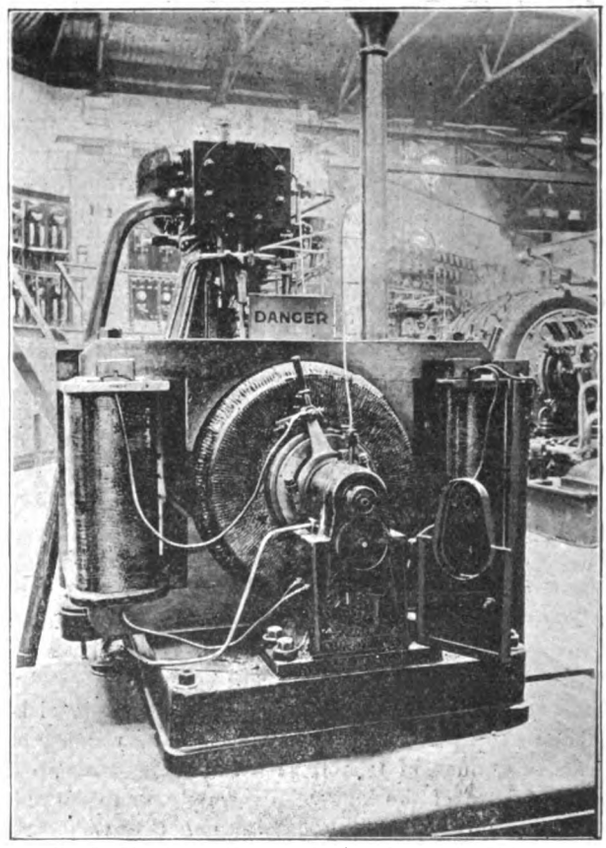

FIG. 2.—The Siemens 10-ampere Constant-Current Arc Lighter..

traction. Each battery consists of 240 cells of the R type in lead-lined teak boxes. The capacity of each battery is 350 ampere-hours on a one hour's discharge, or 600 ampere-hours when discharging over six hours. These two batteries will normally be quite independent of each other, but should necessity arise they can be coupled together in parallel and connected to either the lighting or the traction load. No regulating cells are used on either battery, so that no difficulty arises from the fact that the accumulators are at a considerable distance (about 100

Digitized by Google

yards) from the switchboards. The extension of the station from time to time has been accompanied by the usual increase in the size of the generating units, and has involved the scrapping of a number of small units. Thus, when Mr. Wilmshurst first went to Derby, they were working 13 different steam sets in parallel when the winter peak was being supplied, and now there are only five steam alternators in the station.

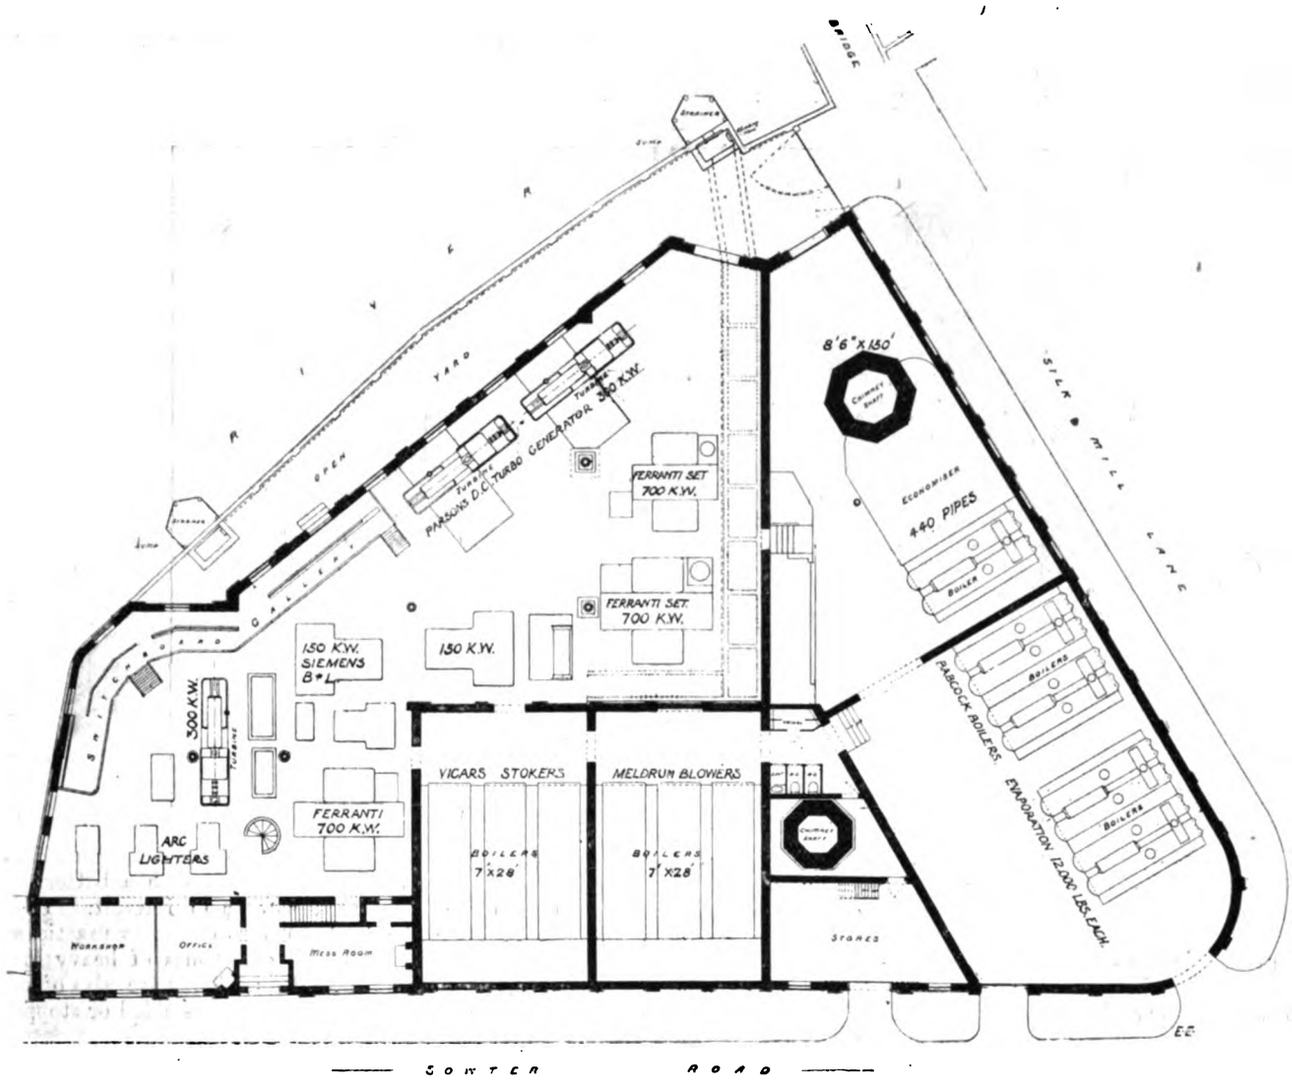

FIG. 3.—Plan of the Derby Power House.

With the introduction of tramways there has arisen a need for continuous current, which is also being introduced for lighting in the area within a half-mile radius from the station. This current is now being supplied from the three

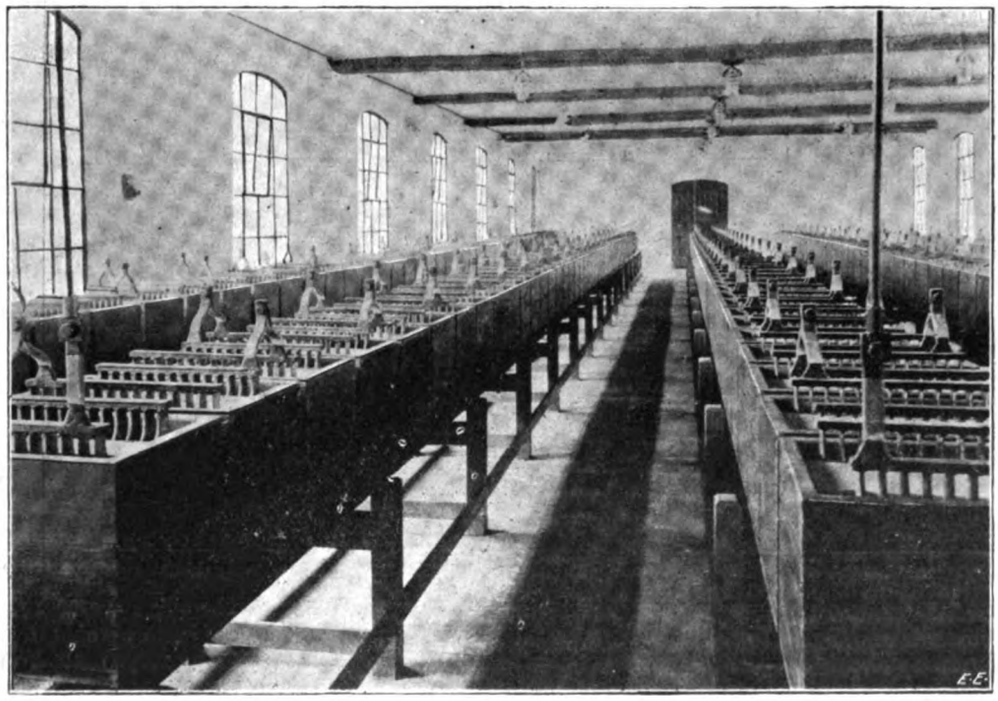

FIG. 4.—The Traction Battery (Chloride type) at Derby.

Digitized by Google

300-kw. Parsons turbo-generators. Two of these machines can be seen in Fig. 5. The direct-current generators driven by these turbines are provided with series compensating windings in the field cores. These windings enable a fixed lead of the brushes to be maintained at all loads. The brush gear is of the usual gravity type, with gauze brushes pressing against a corrugated commutator. The dynamos can be worked either as shunt or compound machines, and the voltage can be varied from 480 up to 620 volts. When running as compound machines, they are arranged to give about 560 volts at full load and 500 volts at no load. These turbo-alternators run at 3,000 revolutions per minute, and the noise made by the ventilating vanes at the end of the armature core leaves no doubt as to which of the turbines is running. In connection with the battery for the tramway circuit a reversible booster is used of a new type. This booster was supplied by the Lancashire Dynamo and Motor Company, and is constructed under the Turnbull and McLeod patents. A view of this machine is shown in Fig. 6, which gives a good idea of the present appearance of the old station This booster is designed for a working current of 200 amperes normal, and 300 amperes for one hour, and to supply 70 volts for prolonged periods and 120 volts as a maximum. The machine runs normally at 800 revolutions per minute. The field magnets are laminated throughout, including the yoke, giving the quick reversal so necessary for traction work.

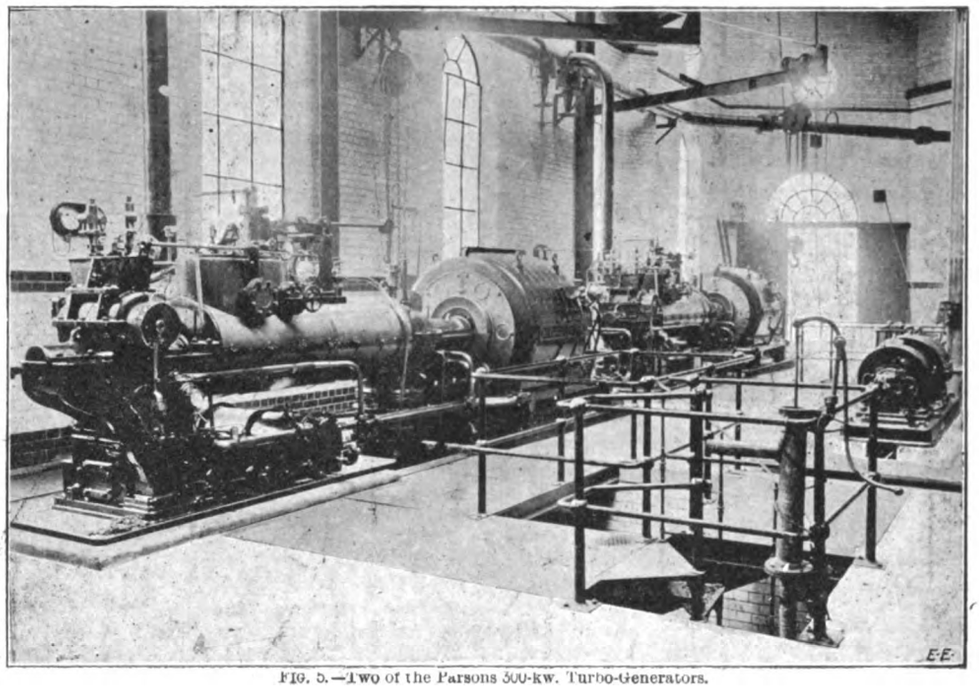

FIG. 5.—Two of the Parsons 300-kw. Turbo-Generators.

The following details of these boosters, which are chiefly used for working on traction systems with a battery in parallel with the generators, will be of interest. Their object is to keep the load on the dynamos practically constant, the battery discharging at times of heavy load and charging at times of light load. They are also of use in works where the motors are large, and started or stopped frequently, or in any other place where the load is of a varying character. Taking into account the large variations in the voltage of a battery (not only with varying current, but with the same current at different times), it is evident that the first requisite is an exciting coil which shall always make the sum of the battery and booster voltages practically equal at all times to the bus-bar voltage. This is accomplished by putting on a coil excited by the

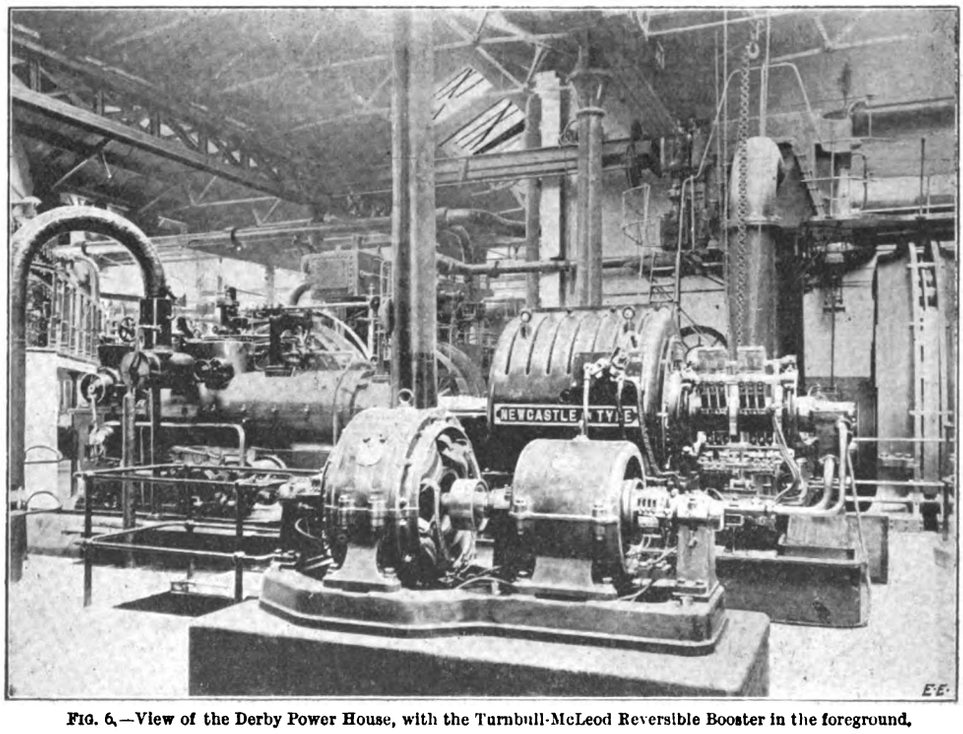

FIG. 6.—View of the Derby Power House, with the Turnbull-McLeod Reversible Booster in the foreground.

Digitized by Google

difference between the battery and 'bus-bar voltage (Fig. 7, coil A). If the booster is worked on the straight part of the characteristic, it will be seen that this coil can be made to give a voltage on the booster armature always equal to the difference between the battery and dynamo

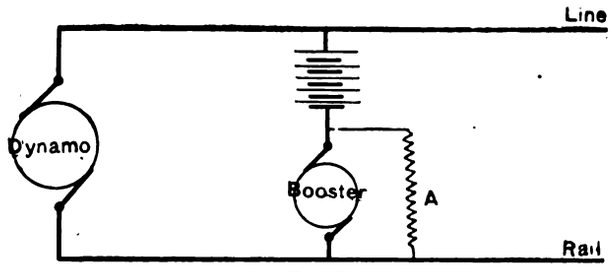

FIG. 7.

voltage, so that no matter what the state of the battery, the booster always brings the battery up or down to the 'bus-bar voltage. If, now, another coil is added, a very small current in this will cause a very large difference in the booster voltage. For instance, a shunt coil across the 'bus bars, B,

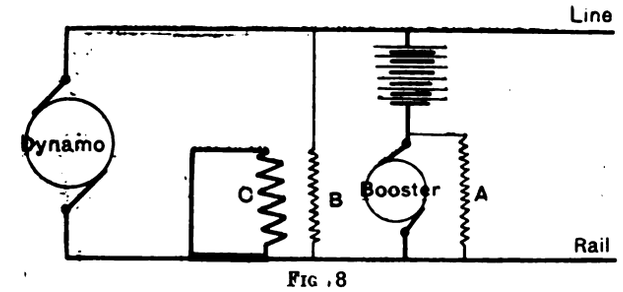

FIG. 8

(Fig. 8), would increase the voltage on the booster, which again would increase the strength of coil A, and the battery would heavily charge. If, on the other hand, instead of B, a coil is put on wound in the opposite way, the voltage of the booster would be altered so as to produce a heavy discharge. This last coil is a series coil, C, arranged to carry the whole or part of the dynamo current, and is arranged so as to oppose the coil B. Then any increase in the ampere-turns of B above C will cause the booster to build up so as to heavily charge, and any decrease of B below C will cause the battery to discharge. A few series turns are usually added in the battery or feeder circuit to make up for the armature reaction and C R drop of the booster itself. To take the case of the booster on a traction system, if the dynamo tries to take an overload, the coil C would overpower B and the battery discharge until equilibrium was restored. On the other hand, if the dynamo current tries to reduce on light load, B overpowers C and the battery charges until they are balanced. As the booster depends for its control on the dynamo current, and not on any balancing of voltage depending on the dynamo characteristics, compound machines can be used as well as shunt, and all trouble from hunting and kindred causes is avoided. Most boosters which do not depend on the falling characteristic of a shunt dynamo rely on the drop in volts on the battery and booster in discharging, which is balanced by a series coil in the feeder. If this coil is not exactly of the right strength, the battery discharges too much or too little, usually varying with the state of the battery. The particularly valuable property of a coil in the dynamo circuit consists in the fact that it can be made as strong as desired and always balanced by a regulator on the shunt coil to fix the dynamo current at anything required, and if the current *should* vary, acts with very great force to bring it back to the normal again, thus making the booster very stable and greatly facilitating

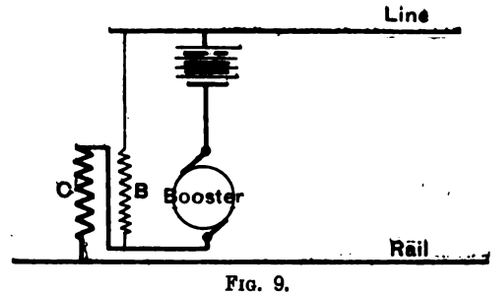

FIG. 9.

paralleling. If it is desired to use the battery and the booster on the line without the generators, coil A is disconnected and coil C connected to help B, giving the battery a constant voltage with varying load (Fig. 9).

The Lancashire Dynamo and Motor Company have also supplied to Derby a three-wire reversible shunt-wound booster for use on the lighting battery, having a capacity of 100 amperes continuously, 200 amperes for one hour, with a maximum boost of 70 volts per side; also two balancers, each made up of two four-pole machines of their standard make.

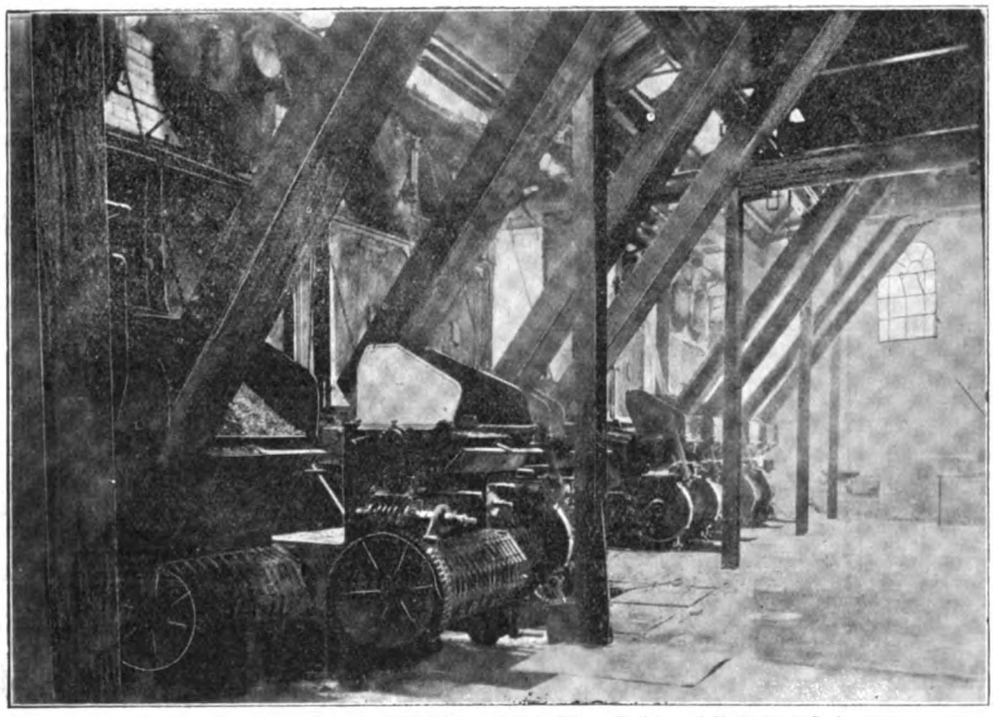

FIG. 10.—The New Boiler House at Derby—Babcock-Wilcox Boilers and Chain Grate Stokers.

In Fig. 10 we give a view of the new boiler-house, which contains five Babcock and Wilcox boilers, each able to evaporate 12,000lb. of water per hour. These boilers are

Digitized by Google

fired by means of chain-grate stokers, which are fed from overhead coal bunkers. The coal supply for the works is not brought by water up the River Derwent, but it has to be carted through the town. The river is, however, exceedingly useful for condensing purposes. Owing to the fact that independent condensing plants are placed in the basement under each generator, it is possible to obtain a high vacuum, and 28in. is quite a common vacuum on the turbo sets.

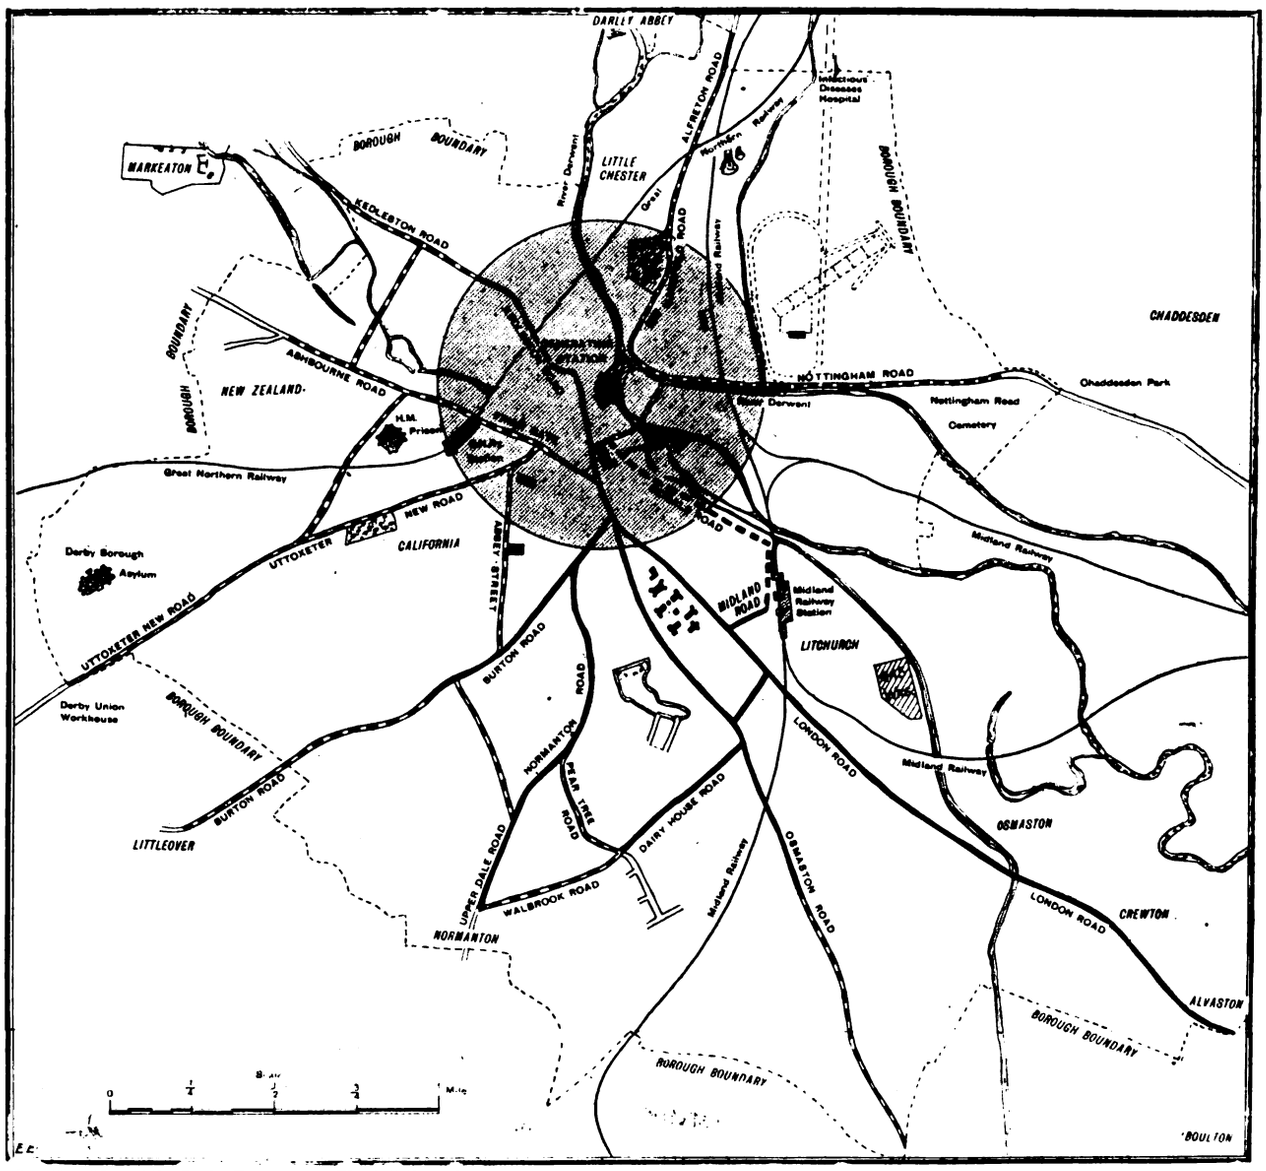

FIG. 11.—Map of the Derby Tramways. The full lines show tramways running or nearly completed. The dotted lines are authorised routes to be added when the sewers are completed. The shaded area denotes the portion of the town in which continuous-current supply is to be given

Steam is supplied superheated both from the Babcock and Wilcox boilers and from the older Lancashire boiler. This superheat, however, is not carried to an excessive point, as 120deg F. is about the limit.

Coming now to the load on the station, this has shown a steady increase, and is remarkable for the large number of motors supplied. Thus, in the year ending March, 1903, no less than 1,264,432 units were sold, and for the past year this has gone up to 1,490,611. These figures are independent of the tramways, as it is only during the past two or three weeks that tramcars have been regularly at work. The aggregate horse-power of the single-phase motors now being supplied is 1,350. These are giving great satisfaction, and are largely the property of the Corporation, let out to the consumers on the hire-purchase system. Out of this aggregate some 280 h.p. are used in one timber yard, in which there are some motors of 40 h.p. each. There is also in this yard a 6-h.p. Heyland motor

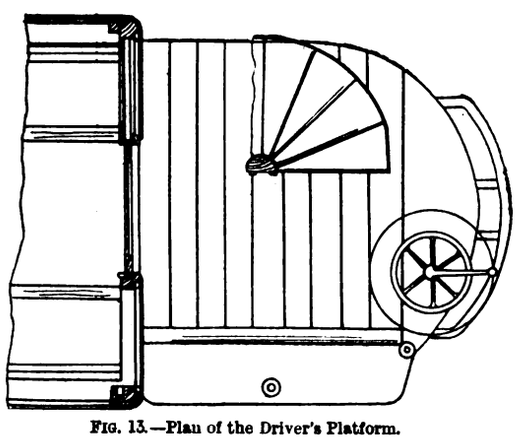

FIG. 13.—Plan of the Driver's Platform.

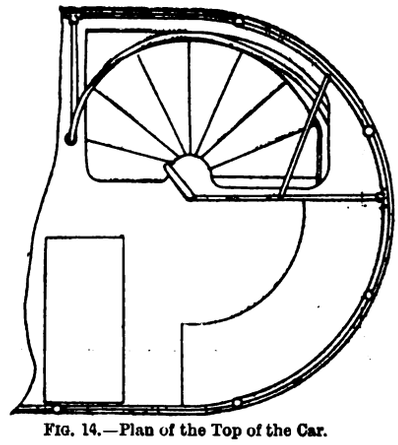

FIG. 14.—Plan of the Top of the Car.

Digitized by Google

coupled on to a lift, which is giving great satisfaction. Some ironworks also take supply for motors at an ggregate of 270 h p.

The tramways at Derby are being constructed at the same time as the reorganisation of the sewers, and in consequence the lines cannot be laid in any street until after the new sewers have been put in. The map (Fig. 11) shows the routes which have been authorised and for the

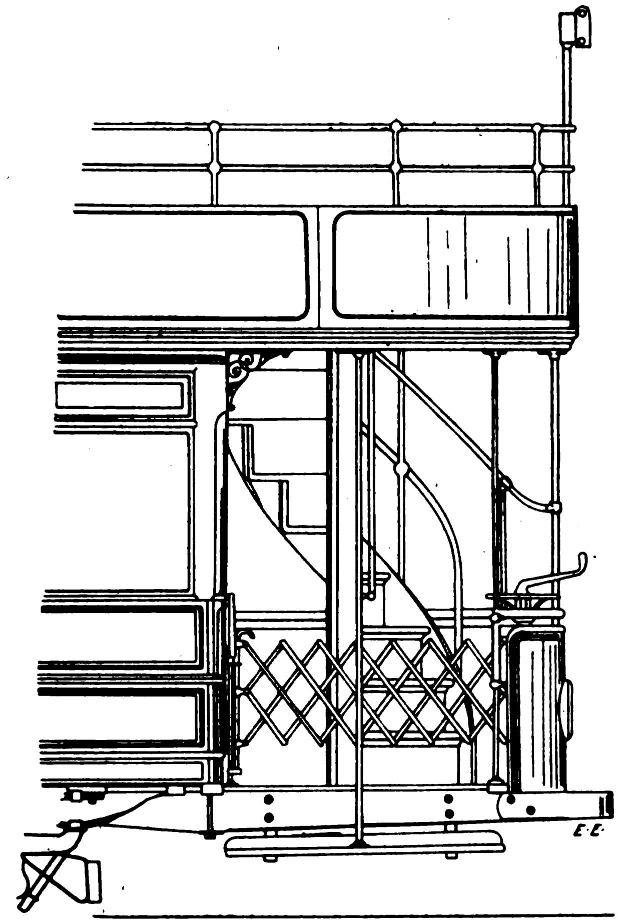

FIG. 12.—End of the Derby Car, showing Semi-reversed Stairway.

construction of which powers have been obtained. Those routes represented on the map by full black lines are either opened or in course of completion. The dotted lines represent routes which will be equipped as soon as possible after the new sewers have been laid. The tramways in the London-road and Osmaston-road, with their branch lines,

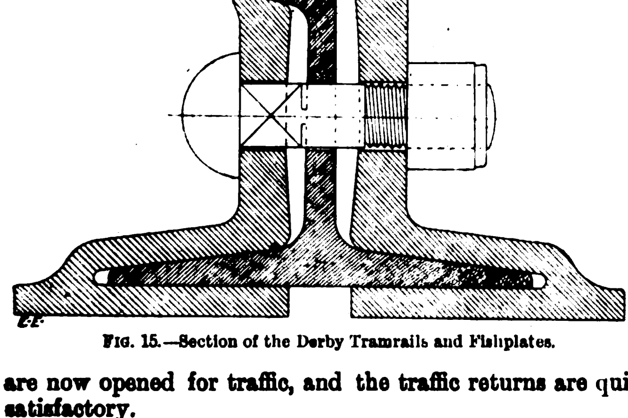

FIG. 15.—Section of the Derby Tramrails and Fishplates.

are now opened for traffic, and the traffic returns are quite satisfactory.

The car-sheds now completed in Osmaston-road can house 30 cars, and are complete with cleaning pits, repair shop, stores, etc. Eventually another car-shed will be constructed at the other end of the town. The cars now running are of the Brush make with Brush trucks and the B.T.H. K10 equipments. They have three brakes—*i.e.*, electric, hand, and slipper. One noteworthy feature of these cars is the semi-reversed stair shown in Figs. 12, 13, and 13. The advantage of this stair is that the view of the driver is not obstructed by the stairs, as is the case with the reversed stairs. The pitch of the stairs is, however, rather greater if compared with the tread in this new type of stair than is generally adopted. The car-shed was designed by and erected to the approval of the borough engineer, Mr. J. Ward, M.I.C.E., who also was responsible for the track work. This work, and also the overhead equipment, for which Mr. Wilmshurst was responsible, were carried out by Messrs. J. G. White and Co. Fig. 15 shows the section of rail adopted and also the special fishplate for securing a stiff joint. The wheel details are shown in Fig. 16.

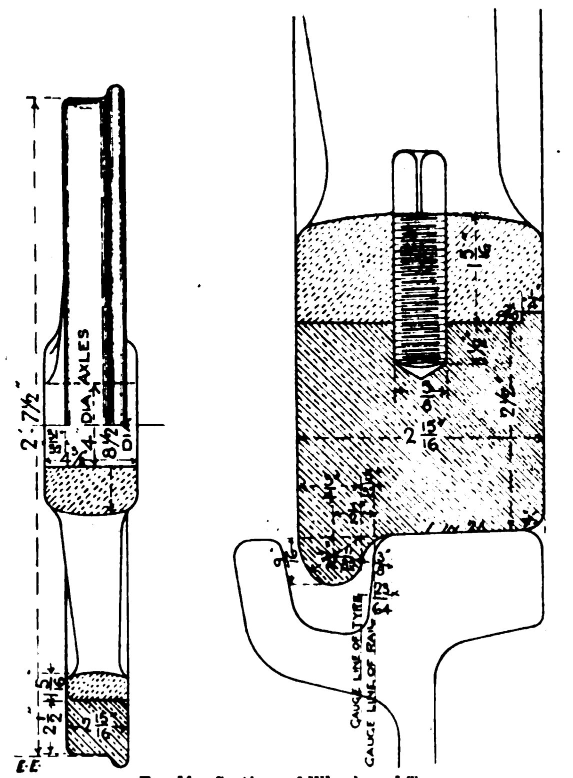

FIG. 16.—Sections of Wheels and Tyres.

It will be seen from the above that Derby will in the near future have a complete system of electric tramways, which is much needed in the town. The introduction of these will help the electricity supply in many ways, and hasten the conversion of the central portions of the supply to the direct-current system. We have to thank Mr. T. P. Wilmshurst and Mr. T. Knatchbull-Hugessen, the mains superintendent, for their kindness in showing us the works on Monday last.

WIRELESS TELEGRAPHY.

BY R. G. BLAINE, M.E., A.M.I.C.E., ETC.

(Continued from page 203.)

Wireless Fire-Alarm.—The importance of automatic fire-alarm systems, especially in centres of population, is obvious. That this importance is recognised is evident from the high prices at which shares in some companies owning patents for apparatus of this kind stand. But an ordinary fire-alarm fails to indicate exactly the position of the fire. That of M. Emile Guarini, using the known laws of ether-wave signalling, accomplishes this very important function, at the same time being automatic.

The principle of M. Guarini's system is that of most automatic fire-alarms, in that a mercurial thermometer acts as the basis of the alarm. Two platinum contacts fused into the glass walls of the thermometer tube are in a circuit including a battery and relay. The circuit is completed by the expansion of the mercury in the thermometer when exposed to the increasing heat of the fire. The circuit may be arranged so that the alarm shall act when the temperature reaches any fixed limit, which, of course, must be above that of any ordinary summer temperature. The

Digitized by Google

novelty of M. Guarini's system, however, lies in the fact that communication between the thermometer in the premises protected and the fire station is accomplished by Hertz-wave telegraphy. Thus no connecting wires are necessary, and the distance up to 20 or 30 miles is of little consequence. The alarm circuit includes a battery and relay, the armature of which acts as a detent, preventing, under normal circumstances, a contact wheel driven by clockwork from acting. When the circuit is completed, through the expansion of the mercury, the armature of

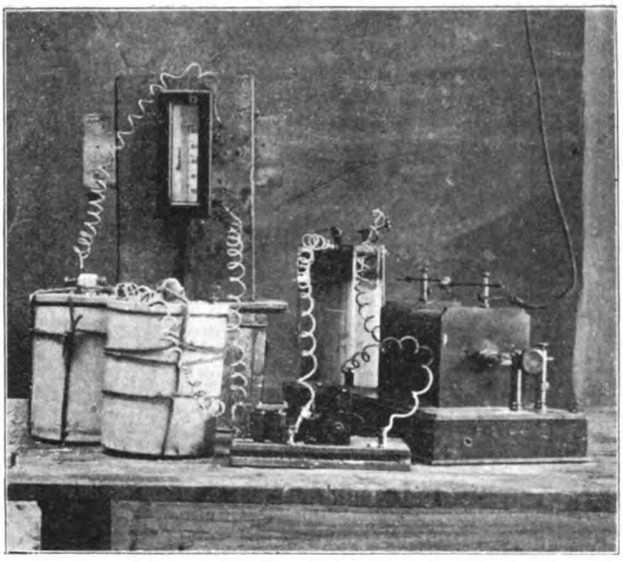

FIG. 77.—Guarini Wireless Fire-Alarm Transmitter.

the relay is attracted; this wheel is released, and the latter revolving makes a series of contacts with a fixed brush which is connected through a battery with the primary of an induction coil transmitter. The induction coil secondary is connected with the usual oscillating circuit and aerial with earth connection. The transmitting apparatus is shown in Fig. 77. The apparatus, it will be seen, are well protected, so that the alarm may have a considerable time in which to act before the temperature is so high as to destroy the transmitter itself. The receiver is shown in Fig. 78, which has the usual coherer battery, Morse

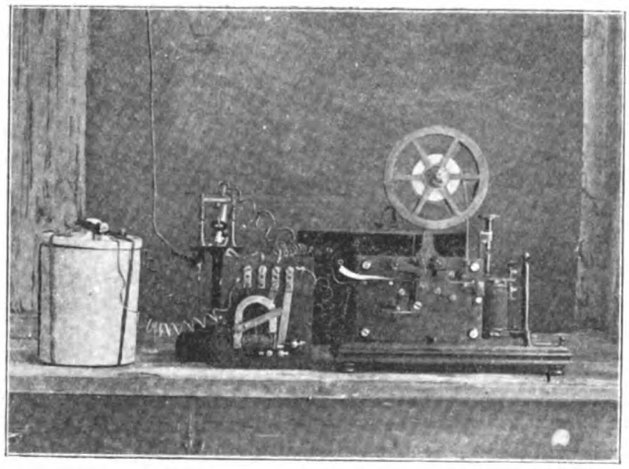

FIG. 78.—Guarini Fire-Alarm Receiver.

printer, etc. The first incidence of the ether waves rendering the coherer conducting, closes a circuit including a call bell. The contacts on the wheel of the transmitter determine the signals, and thus not only an alarm is given, but the name and address of the premises or even the *room* protected by a given instrument are repeated again and again and registered by the receiver. The same receiver can be made to serve for different thermometers placed in distinct buildings or in different rooms of the same building.

This up-to-date application of wireless signalling appeals to all who wish to avail themselves of the most recent advantages resulting from scientific research. As fires are more numerous and more dangerous by night than by day, it is as well to remember also that wireless signalling can be carried on with more certainty at night than in the daytime, and over longer distances.

THE NEW GERMAN SYSTEM—"TELEFUNKEN."

This system of wireless telegraphy arises from the amalgamation of the two systems already described—the "Braun-Siemens" and the "Slaby-Arco"—the one owned by the Gesellschaft für drahtlose Telegraphie, and the other by the Allgemeine Electricitäts-Gesellschaft. This fusion of systems took place in the summer of 1903, the apparatus of the new system being constructed in the workshop of the two companies, but for alterations and repairs required on short notice, and for the production and *testing* of new models, a special workshop employing about 100 carefully trained workmen and assistants has been established. For outdoor experiments with aerial conductors, and in relation to syntonising and carrying distance tests, six stations in and around Berlin have been established.

The two systems have over 20 patents in Germany alone. Amongst these may be mentioned that of 1898 for the transmitter arrangement, in which an oscillation circuit with condensers and a spark-gap with a large amount of energy excites the aerial conductor slightly deadened to self-oscillations. A similar arrangement for the receiver was patented in 1901, consisting of a closed oscillating circuit, which by a clear and pronounced self-period renders the receiving apparatus sensitive to a definite transmitter frequency only, thus eliminating to some extent disturbances emanating from foreign transmitters. A patent reserving to the company the resonance arrangements of four oscillation circuits of transmitter and receiver for certain modes of mounting has been followed by others, granted or applied for, in connection with transmitter arrangements for reducing loss by deadening in the spark-gap—the first successful attempt, it is claimed, made by any company to deal with this hitherto chief cause of loss of energy. The patent electrolytic wave-detector or coherer (Schloemilch) already referred to (see p 630 *ante*) is, no doubt, one of the chief sources of success. It is claimed to be the simplest and most reliable receiver yet produced.

The fact that 250 stations on this system are (according to information supplied to us from Berlin) now working, and that the number is rapidly increasing, shows the importance of the system. The annual cost of working in warships amounts, we are told, to about £20 (we presume this means £20 per ship). A great feature of this system is the portable station (see p. 79, July 15, 1904). Concerning the reliability of these stations and their use in war, an officer of the general's staff, referring to the manœuvres in an article in the *Militär-Woehenblatt* of November, 1902, says: "The telegraphists employed the Braun-Siemens system of spark telegraphy, which worked exceedingly well. The transportable station was daily in great requisition: it transmitted orders and reports between the general in command of the fifth army corps and the cavalry division. . . . With the Morse printer the stations worked reliably at a distance of two days' march, with other operators at a distance of three or four days' march."

Distance of Signalling. — The distance of successful signalling is determined by the size of the aerial conductor net and the magnitude of the source of electric energy necessary for radiation into the ether. As early as 1902 some experiments by the company were made from the Oberspree works of the Allgemeine Elektricitäts-Gesellschaft. Four chimney stacks, each 70m. (229½ft.) high, were used to support a square aerial net consisting of about 100 wires running down in funnel shape to the generator. An alternating-current supply of about 15 kw. was taken from the engine-room. This current converted to a pressure of about 50,000 volts supplied the exciting system. The enormous oscillations with a frequency of about 900,000 per second excited the aerial net. On the very first day of the reconstructed trials legible messages were transmitted to Karlskronain, Sweden, 450 km. (about 281 miles), the receiving wires being only 35m. (82ft.) high. The company now guarantee communications over distances

Digitized by Google

of upwards of 1,000 km. (625 miles). Especially in summer it is, however, a well-known fact that the distance of successful signalling varies much with the state of the atmosphere. Hence a large *factor of security* is necessary to ensure successful communication at all times. Thus to cover successfully a distance of 100 miles under all conditions, it may be necessary to utilise energy sufficient to cover 300 miles under favourable conditions.

The Province of Wireless Telegraphy.—The owners of this system have made many experiments, and give it as their opinion that in the immediate future neither absolute exemption from disturbance nor complete secrecy—at least for comparatively long distances—is to be expected. Even if this be true—and it is disputed by some authorities—wireless telegraphy has in numberless cases already done excellent work. The first primitive contrivances of wireless apparatus were sufficient, and various navies introduced them on their ships. Now, however, an important problem presents itself. A company supplying such apparatus as are used on board, say, the ships of a large navy, is required to make the range of all the instruments as nearly alike as possible; in other words, they are all to be as nearly alike as possible in the time period and wave-length adopted, so that intercommunication may be easy and interference from outside workers, to some extent, at least, secured. To do this a wave-meter becomes a necessity, and this the system here referred to supplies. This apparatus has already been described in these articles, and by its use a station may be erected in any part of the world with apparatus suitable to receive messages from any other given station. Further, if it were desirable, this apparatus could be used to determine the wave-length employed by any other rival station, or station in the hands of an enemy. The necessary alteration being made in the receiving circuit of the station supplied with the wave-meter, the messages from the rival or enemy could easily be read if dependence were placed merely on the security given by resonance effects. Of course, a code might be employed to get over this difficulty, but apart from this suppositious case the utility of the wave-meter is evident.

This very weakness of wireless telegraphy—viz., the fact that it is necessary to radiate into space, and hence all within a given distance may read who care to suit their stations to the radiations—proves, in some cases at least, its most desirable feature. In army work, for instance, the fact that a telegram may be *simultaneously read by many receivers*, is of the greatest value, as the orders of a commanding officer can thus be received *simultaneously* at many quarters, and combined movements of large bodies of troops in scattered positions may thus be made with the greatest precision. This feature has been fully worked out in Germany, and the excellent portable sets there used testify to the ingenuity displayed in taking advantage of the above peculiarity of wireless signalling. Light military wagons have been constructed to carry not only the whole apparatus of a station, but also the necessary supply of current, kites or balloons being used to carry the aerial wires. The use of wireless signalling to and from railway trains in motion has been advanced by this company. With horizontal aerials on the trains and the ordinary telegraph wires on the line the military railway from Berlin to Zossen has been equipped for wireless telegraphing, and it has remained in uninterrupted use since the close of 1903.

The use of the system in the Imperial and commercial navy is very striking, the shores of the North Sea and Baltic being netted by an unbroken series of stations belonging to the German navy. *All* telegrams are taken up and sent off within a range of 150 km. (93⅔ miles) at the low tariff of 9½d. per 10 words, irrespective of the nationality of the dispatching vessel or of the system employed on it. The shores of the United Kingdom are surrounded by many similar stations, but we may have some disquietude as to whether these stations will soon be under State control, and whether State resources will be used to further commercial enterprise as in Germany.

There is another little disquieting statement that one may mention. The owners of this system in their pamphlet, now in the press in Germany, say that "On Sept. 26, 1903, their Lloyd-Hall station at Bremerhaven exchanged telegrams with the Marconi station on the fast steamer 'Kronprinz Wilhelm,' 257 km. (161 miles) away." They also say, "In like manner we can catch up, on the North Sea coast, telegrams which the Marconi apparatus at Poldhu strives to fling across the Atlantic. Similarly, we can force the Marconi receiver at Poldhu to take up our telegrams together with the messages coming from America, so that when the two arrive simultaneously . . ." The writer desires to avoid controversial matters, so prefers not to give the remainder of the sentence, and distinctly desires to state that he has no knowledge of the truth or otherwise of the statement. The first part of the pamphlet ends with the pregnant words, "all we need is to work with a like wave." The disquieting part of this matter is that as our navy is equipped with Marconi apparatus, one cannot help wondering whether our German friends are as successful in connection with the reception of our naval messages as they say they are of the messages referred to, and whether a code would be of much use in time of war.

(To be continued.)

PRESSURE DROP IN ALTERNATORS.

BY WILLIAM CRAMP.

The Heyland diagram for polyphase motors shows clearly all the effects observed when one field produces upon closed conducting circuits by its rotation a second rotating field. It states that the currents induced in the closed circuits by the rotation of the first field follow what is now known as "the semi-circle law"—*i.e.*, their values are given by the length of lines drawn from one extremity of a diameter of a semi-circle to the circumference.

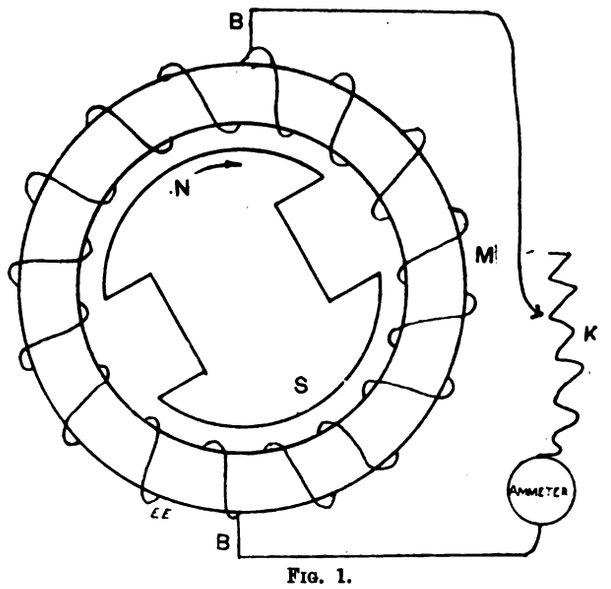

FIG. 1.

Now, an alternator consists of a series of rotating fields and a number of closed circuits upon which these fields act. One of the simplest forms of alternator is that shown in Fig. 1, where N S is a revolving permanent field, B B a ring armature connected to the external circuit, K, at the points B B. B B are, therefore, not brushes—*i.e.*, there is relative motion between them and the field N S, and they are fixed with respect to the windings. We shall assume that the distribution of the field set up by N S is sinusoidal around the armature, B B.

Now if N S revolve at a uniform speed in a direction, say clockwise, it will set up in the coils of the ring and in the external circuit an alternating current, which current will in turn set up an alternating field along the line B B. This field may, by the method of Prof. Ferraris,* be resolved into two equal magnetic fields, rotating about the armature in opposite directions, each field of half the maximum strength of the resultant or actual field. These two fields pass one another on the line B B. The reaction of one of these—viz., the one which rotates in the

* Galileo Ferraris, *The Electrician*, p. 110, 1894.

Digitized by Google

same direction as the field N S—may, by the laws of the Heyland diagram, be easily taken into account. The reaction of the other may be considered as follows: Imagine the two similar component rotating fields, I. and II., starting from B (Fig. 2) and rotating with equal velocity about the armature, C, which, for the sake of simplicity in this figure, is drawn with a simple drum winding, the obvious equivalent diagrammatically of the ring armature in Fig. 1. The field II. revolves clockwise—*i.e.*, in the same direction as the original field, N S. Suppose that at the moment which we are considering the sense of this field is north at N. The sense of field I. is, therefore, north at N_1. As field II. proceeds in the direction of the arrow head it will produce upon reaching the conductor, A, a current in the

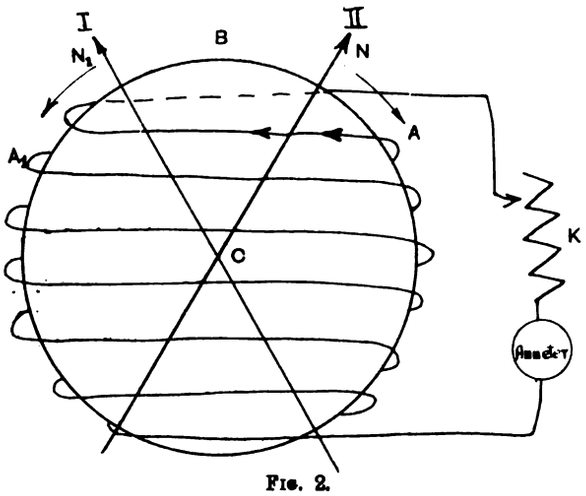

FIG. 2.

direction shown. Field I., by this time arrived at A_1, will be found by Fleming's hand rule to be producing a current *in the same direction in the same coil.* That is, though each field exercises upon the armature a tendency to turn (or torque) in an opposite direction to its fellow, each produces a current in direction and time about the armature, C, exactly similar. But the reaction upon the field N S is produced or transmitted by means of the current in the armature coils; thus it is clear that, so far as reaction upon the field N S is concerned, the result of field II. is just to double the influence of field I.—that is to say, both fields produced by N S may have their reaction upon N S represented by a similar constant field rotating in the same direction as N S.

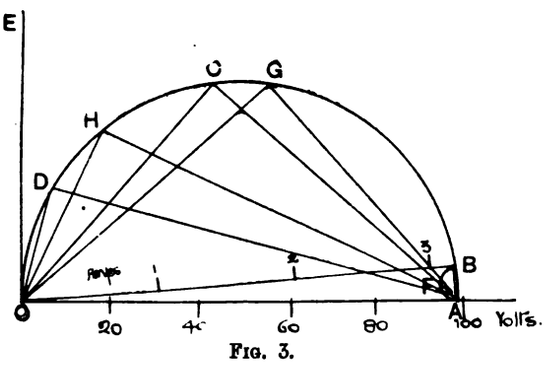

FIG. 3.

The problem, therefore, is exactly that dealt with by the Heyland diagram, for, by reference to Fig. 1, it will be seen that the E.M.F. produced in either half of the ring is a maximum when N arrives at M. If there is very little self-induction in the circuit, the current will at the same instant be a maximum, but there will be no field (or practically none) along the line B B. This is only possible when the resistance of the circuit is extremely large, and the current, therefore, practically zero, thus corresponding to the starting point, O, of the semi-circle diagram (Fig. 3), where O E represents the alternator E.M.F., and lines from O to the semi-circle give the alternator current. The other extreme position—*i.e*, when the alternator current is equal to O A—though it can never be realised in practice, corresponds theoretically to the condition when in Fig. 1 the lag of current behind the E.M.F. is 90deg., so that, though the E.M.F. is still a maximum when N arrives at M, the current is a maximum when N arrives at B. Under these conditions the resistance of the circuit is zero, the current is entirely a magnetising (rather a *de*-magnetising) current, and since it is as great as it can ever be, it must be just balancing the field N S—*i..e*, the ampere-turns of the armature when the armature current is a maximum are exactly equal to the field ampere-turns.

It must be well understood that the Heyland diagram only answers to those cases in which the coefficient of self-induction of the circuit considered is practically constant, a state of affairs usually existing in polyphase motors because the magnetic densities employed are relatively low, and thus every increase of current produces a corresponding increase of armature field. This, however, is not the case with single-phase alternators; the induction in the teeth of the armature is frequently high, as also that in the pole-faces, and it becomes necessary sometimes to take this into consideration in the diagram. First of all we will show by a small test case that the alternator follows the law given above if the saturations are low. We must bear in mind that the resistance to which the diagram refers is the *total resistance in the circuit*, the E.M.F., the *total E.M.F.*, generated by the alternator. The table below gives details of a test of a small *Crypto* alternator (built for experimental work and kindly put at my service by the Crypto Works Company, 29, Clerkenwell-road, E.C.) run at a constant speed of 2,500 revolutions per minute, and with a constant exciting current of 0·7 ampere, this exciting current being selected as showing all the points of the construction before saturation sets in.

READINGS OF ALTERNATOR.

Exciting current	0·7 amps.
Short-circuit current	3·15 ,,
Volts, open circuit	99
Load, 93 volts	0 8 ,,
86 ,,	1·35 ,,
68 ,,	2·05 ,,
60 ,,	2·35 ,,

We proceed to set out the readings as follows: Choose a scale for the voltage so that the line O A (Fig. 3) represents the open-circuit reading. Now, on O A describe a semi-circle O D A, then if the *load* is non-inductive, as it was in this case, O D, O C, etc., are values of the current in the circuit corresponding to A D, A C, etc., which represent the product of current into the total resistances of the circuit, which is here $R_a + R_x$ = resistance of armature + external resistance. If, as in this case, the alternator is to be used upon a non-inductive load, and with normal excitation the short-circuit current is not too large for the armature winding, and the magnetic saturation does not rise to high values in the alternator, we can predict the performance of the alternator on varying loads with only the open-circuit and short-circuit readings. For having set out the semi-circle upon O A as above, we calibrate the current line as follows: the short-circuit current is 3·15 amperes and the resistance of the armature is 2·4 ohms, therefore on short-circuit the C R drop in the circuit is 7·56 volts. To the same scale of volts to which O A is drawn, take a length equal to 7·56, and from the point A cut the semi-circle in B, then O B represents 3·15 amperes, so that the current scale is fixed. For any current, then O C, the external voltage, is A C – [O C . R_a].

Now, since the C R drop in the armature is proportional to the current, and always in phase with or forming a portion of such lines as A C, A D, and since it has its maximum value when the current is a maximum, it follows that we may show the C R_a drop corresponding to any current represented by O C by describing a semi-circle upon A B, when A F (that portion of A C which is cut off by the semi-circle A F B) is seen to represent the C R_a drop corresponding to the current O C. Thus, C F is the actual terminal voltage corresponding to current O C, and so on. For the particular alternator given above I have plotted these readings by ordinary rectangular co-ordinates, and have marked by crosses on the same diagram the theoretical readings, while dots give the actual readings of the alternator taken upon load as given above. The letters in the two diagrams correspond (Figs. 3 and 4).

So much for the case of non-inductive load. In predicting the fall of pressure upon an inductive load, we have

Digitized by Google

to remember that the densities used in alternate-current apparatus, such as transformers and induction motors, are low, resulting in the coefficient of self-induction being constant over working loads. We have then simply to consider a circuit made up of apparatus which increases the self-induction of the original circuit by a definite amount. This is only equivalent to multiplying the armature leakage by a definite amount, and, therefore, it is clear that the current and voltage in the total circuit will follow the same general law. The only difference is that now to get the actual short-circuit current, we must obtain that current which would flow when the *resistance* of the inductive apparatus connected to the alternator is reduced to a minimum.

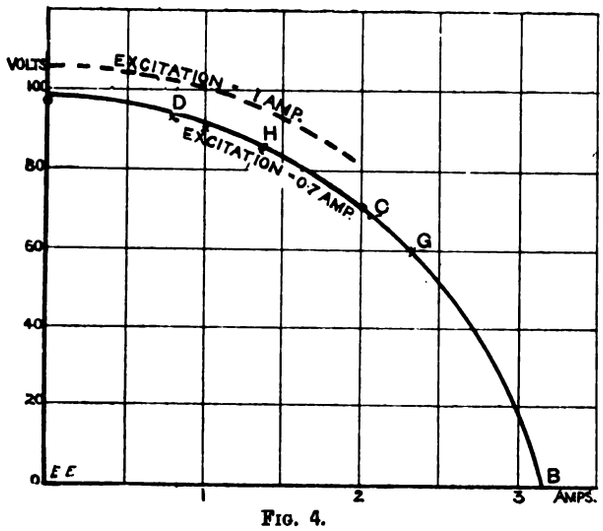

FIG. 4.

The connection between current and voltage in such an apparatus as a short-circuited transformers is (as in the case of an alternator) nearly a straight line until saturation sets in. We may, therefore, obtain such a curve for the particular inductive load by finding one or two points upon the line and producing it until we obtain the current corresponding to the open-circuit voltage of the alternator. We are then able to compare the self-induction of the alternator with that of its load, taking care not to omit to get the absolute short-circuit current for the load—*i.e.*, that which corresponds to O A in Fig. 3—by finding O B from the short-circuit curve, measuring the resistance of the apparatus, and setting out

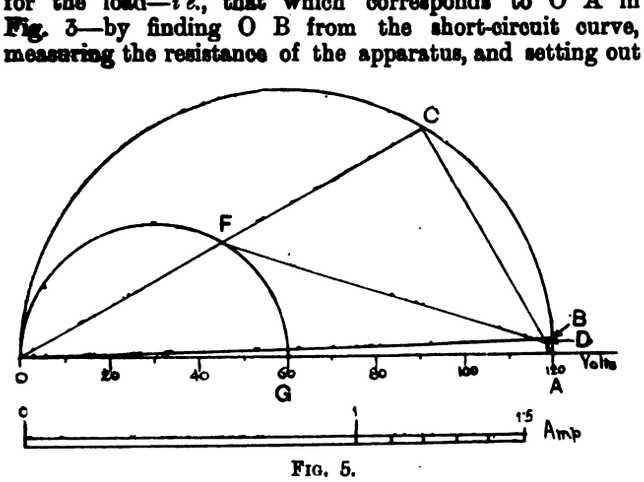

FIG. 5.

B A to represent the C R drop. An actual case will, perhaps, make this more clear. A transformer was connected to the alternator used above, and the exciting current of the alternator was raised until the voltage at the terminals of the primary was 120, while the secondary was short-circuited by a negligible resistance. The current was then found to be 3·2 amperes in the primary circuit, and the equivalent resistance of the apparatus was 0·6 ohm. A figure was then set out like Fig. 3: O B = 3·2, B A = ·6 × 3·2, O A = 120. It was then found that O A to the ampere scale was also practically 3·2. Upon altering the excitation of the alternator so that its open-circuit voltage was 120, and then short-circuiting it, the absolute short-circuit current corresponding to O A was also found to be 3·2 amperes. It follows that when with this latter excitation the alternator is connected to the transformer, and the secondary of the transformer is short-circuited, the absolute short-circuit current through the whole circuit would be 1·6 amperes, and the voltage at the alternator terminals 60.

Suppose, now, the secondary of the transformer is closed by a variable resistance, or, what is the same thing, an apparatus which by motion produces an E.M.F. tending to reduce the supply current (such as an induction motor). Then, as we have already said, the whole circuit will follow a semi-circle law, and we may draw a diagram like Fig. 3 straight away, as follows: Make O B = 120 volts to scale; upon O A describe a semi-circle, O C A (Fig. 5). Draw A B = R_c . C_s to the same scale in volts to which O A is drawn. (R_c = resistance of circuit, C_s = current on short-circuit.) Join O B, and calibrate in amperes, so that O A = 1·6 amperes. Take now on the semi-circle any point C, and join O C, C A. Then O C is the current in the circuit corresponding to a resistance (or energy) voltage C A. At A set out as before a semi-circle to give the C R_c drop in the alternator. Then C D is the voltage to drive the current O C against the resistance (or E.M.F.'s) in the rest of the circuit. Similarly, since $\overline{OC} + \overline{CA} = \overline{OA}$ = total voltage generated, O C = the total volts absorbed in overcoming the self-induction of the circuit = C. $(L_1 + L_2)\,p$. [Where $p = 2\pi \times$ frequency, f, and L_1 = coefficient of self-induction of alternator, L_2 = coefficient of self-induction of the load.] But $L_1 : L_2 =$

$$\frac{1}{\text{absolute short-circuit current of alternator}} : \frac{1}{\text{absolute short-circuit current of load}}$$

Divide O C then at F, so that O F : F C as L_1 is to L_2, and join F D. Then C F = O C × 2 π f L_2, and therefore the pressure at the terminals of the alternator is = F D volts.

Since the ratio $\frac{O\,F}{F\,C}$ is constant, and C moves on a semi-circle, F also moves on a semi-circle, having its chord along O A, O and F being points on the semi-circle. This has been shown in the figure, and completes the diagram for inductive load. O G is to G A as L_1 is to L_2. We, therefore, have the following rule for the diagram of inductive circuits: Divide the line O A, whose length has been already found, into two parts, O G, G A, so that O G is to G A as the absolute short-circuit current of the load is to the absolute short-circuit current of the alternator under similar conditions of P.D., as already explained. Then the values of the current are given by all such lines as O C, while the terminal volts are given by all such lines as F D. It is obvious that if we make the line O A to represent the short-circuit current of the alternator (instead of short-circuit current of load and alternator), we get C F, representing current in the circuit to the scale of O A instead of O C, as above, F D still representing the terminal voltage.

Two points remain to be discussed: (1) how to get the more important curve of *exciting current against load* for constant terminal voltage; (2) what is the effect of saturation upon the method employed. The second point influences the first, but its effect is easily seen.

To get the *load excitation* curve from these diagrams, we must draw a number of diagrams like Fig. 3 at different voltages, preferably upon the same base line. The open-circuit voltages are best taken from a magnetisation characteristic, the short-circuit readings from a short-circuit curve. It is not difficult then to prick off from the various semi-circles corresponding to the different exciting currents the current lines corresponding to a definite voltage, and these may then be plotted in the ordinary way. In Fig. 4 part of a second load curve has been drawn, corresponding to an exciting current of one ampere. If we desire to find the characteristic for constant voltage and varying load—*i.e.*, exciting current plotted against varying load—we get two points on the curve required from Fig. 4. As a rule, in practice one only requires two or three such curves, for all that is really essential is to know the exciting current corresponding to open-circuit voltage, and that corresponding to the same voltage at full load.

The effect of saturation is to lower the impedance of the circuit in which the saturation occurs, in consequence of

Digitized by Google

the fact that the open-circuit voltage curve turns over quickly, due to saturation, the short-circuit curve also turns over somewhat. This may be allowed for in the diagrams by drawing O A (Fig. 3) first equal to the short-circuit current which would flow if the short-circuit curve were a straight line, and then setting out O A′ equal to the actual short-circuit current. A curve may now be drawn, starting at O and finishing at A′, which partakes largely in its first portion of the form of the semi-circle on O A. Naturally the semi-circle on O G in Fig. 5 will follow the same sort of shape. Though this process may be carried out with some success if necessary, I do not lay great stress on it, as I have found that within the working range of most alternators the impedance is practically constant. It will be seen that the curves shown above are taken with small currents, and it would be interesting to see results taken from larger alternators. At the same time, care has been taken to check the method carefully, and I have to thank Messrs. Pitkin and White for calibrating specially a low-reading ammeter.

The method here detailed enables the performance of an alternator to be predicted graphically when the following curves have been taken, neither of which necessitates the use of large power: (1) open-circuit characteristic; (2) short-circuit characteristic. Besides this we must know the resistance of the full-load circuit and its probable power factor, and the resistance of the alternator armature.

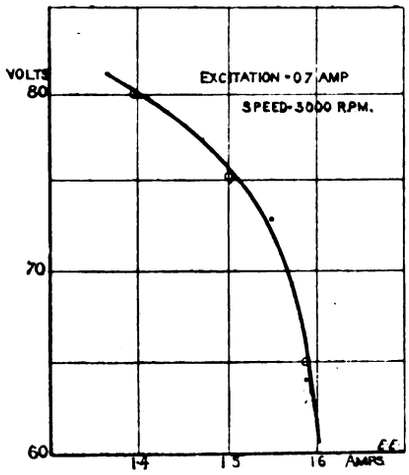

FIG. 6.

It may be noted, in connection with what has gone before, that since the circuits considered have been simple circuits, consisting of various self-inductive coils and resistances, with a definite sine wave of E.M.F. producing a definite current through them, the same sort of diagram would be applicable to all alternate-current circuits That is, that as the foregoing applies to an alternator, it will, with some modifications, apply also to a synchronous motor, and hence to any sort of alternate-current motor driven by an alternator.

In connection with the prediction of alternator characteristics, it is sometimes of interest to be able to foretell by simple geometric construction what will happen if, with a given load, the frequency is varied, the exciting current meanwhile remaining constant. Perhaps the simplest way to develop the construction is to put the well-known formula for alternate-current circuits in terms of the alternator speed. We have

$$C = \frac{E}{\sqrt{R^2 + 4\pi^2 L^2 f^2}},$$

where C = R.M.S. current in amperes;
E = R.M.S. E.M.F. in volts;
R = total resistance of the circuit in ohms;
L = coefficient of self-induction of the circuit in henries; and
f is the periodicity in cycles per second.

In the case of our alternator, all the above quantities refer, of course, to the complete circuit, so that E is the E.M.F. set up by the alternator itself. This is proportional to the speed so long as the excitation remains constant. In the denominator everything is constant except f, which varies directly as the speed, so that we might write

$$C \propto \frac{S}{\sqrt{R^2 + S^2}},$$

where S is the speed of the alternator. Set off a line then as O B in Fig. 7, and divide it up to represent the speed, obviously to another scale it may represent the E.M.F. developed by the alternator.

From the point O, and at right angles to O B, draw O A to a convenient scale to represent the resistance of the circuit in ohms. The length of this line will, of course, be constant, as we are supposing the alternator running on a constant load. Join A B, then A B is equal to $\sqrt{R^2 + S^2}$, and the current corresponding to speed S and resistance R is given by $\frac{S}{\sqrt{R^2 + S^2}}$ (*i.e.*, sin ϕ), ϕ being angle O A B.

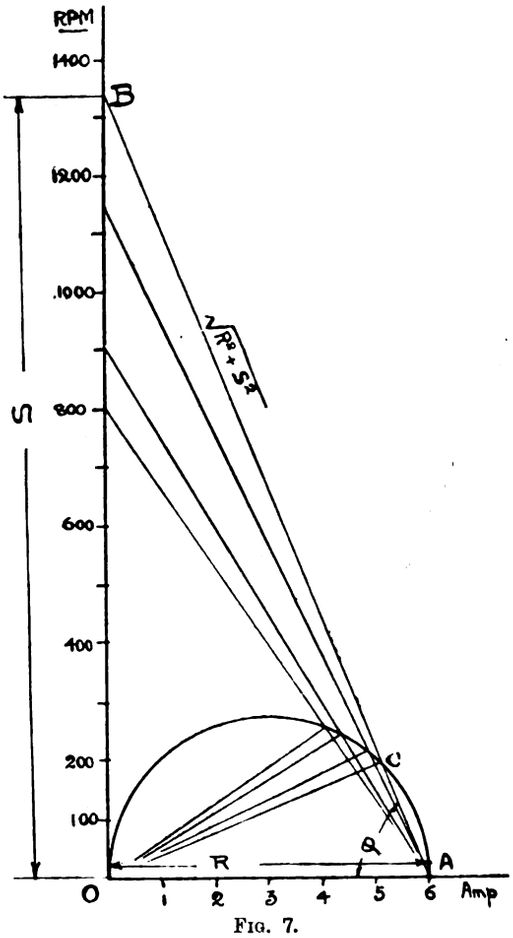

FIG. 7.

In order to get this sine in a more convenient form, from O upon A B let fall the perpendicular O C, then $\frac{O\,C}{O\,A}$ = sin ϕ. But O A is constant, therefore O C $\propto$ sin ϕ—*i.e.*, O C may be calibrated to give values of the current for the various speeds on O B. It will be seen that since O A is constant and O C A always a right angle, as ϕ varies the point C will move upon a semi-circle described upon O A, as shown in the figure.

We will now consider the two limiting cases of the diagram, which are (1) when C coincides with O; (2) when C coincides with A. In the former case B will coincide with O and, therefore, the speed is zero—*i.e.*, the alternator is at rest. In the latter case A B will be at right angles to O A; O A will be the current in the circuit and A B will be parallel to O B, so that the speed is infinite, from which it follows that no matter how fast the alternator run, there is a limit to the current in the circuit. This shows clearly that above a certain speed (say when the angle C O B is about 80deg.) the current in the circuit is practically constant, for O C is almost equal to O A at that time, and the length of O B, which represents the speed, changes from O B to an infinite length, while the current only changes

Digitized by Google

from O C to O A. Now, the angle of lag of the current behind the E.M.F. is an angle whose tangent $= \frac{2\pi f L}{R}$ which $\propto \frac{S}{R}$. Clearly from the diagram this angle is ϕ.

We will now take a case to show how near this construction comes to actual practice. The Crypto alternator mentioned above was run with a constant resistance in circuit and a constant excitation in the field circuit of 1 5 amperes. Fig. 7 has been calibrated to show these readings set out, and it will be found from careful measurement that the agreement with the diagram is very close. The method used in setting out was as follows: It was found that the armature current only rose 0 1 of an ampere between a speed of 1,340 and 2,000; higher readings revealed the fact that the maximum current it could possibly give would be about six amperes. O A was then drawn to scale to represent six amperes, and on O A the semi-circle was described. To this scale a length was taken equal to 5·6, and from the point O the semi-circle was cut at C. A C was joined and the line produced until it cut O B at B. This point was called 1,340, and the distance between B and O divided off as shown. Upon then drawing in lines from speeds 1,444, 904, 796 to point A, and joining the intersections of these lines with the semi-circle to point O, the readings in amperes measured from O were exact to those found from actual experiment.

The above method of setting out the diagram, though it checks the method well, is not to be recommended for constant use. It would be better, knowing the open-circuit E.M.F. corresponding to any given speed and the current corresponding to the same speed, and the total resistance in the circuit, to set out the diagram by making O A equal to this resistance, O C equal to the current, and the intersection of A C and O B equal to the E.M.F. and speed. From this one reading O A and O B may be calculated. Thus, to obtain this diagram it is only necessary to take one experimental reading on any known load, and the corresponding reading on open circuit, and the construction is valuable to the designer as giving him a clear idea of what will be the worth of using an alternator intended for one periodicity for a periodicity slightly higher or lower.

LETTERS FROM AN OLD HAND TO A YOUNG ONE.

III.—On College Life.

My Dear Young 'Un.—You do not start your last letter very brilliantly. After informing me that you have entered College, you ask me on what subject you should specialise; as if a youth your age could afford to neglect anything! Specialisation at an early stage of development is a big mistake. Devote the first 10 years in your profession to getting an accurate general knowledge of it. There will be time enough to blossom out as a specialist when you have formed the necessary supporting-stem of general practice.

If you ask me what, in my opinion, is the fundamental study of all, I should pick mathematics. I am aware that the reading of this will give you a cold shudder, because you are constitutionally inaccurate. Maths. are the finest aid to accurate habits of thought I know of. Even if a man never has to use a differential in the whole of his engineering practice, the precision of thought acquired by the study will extend itself to other spheres of usefulness and make him a more valuable engineer. An inaccurate man is no good in our work. The days are gone when you could mark off the rivet holes in an iron plate by salivating on it Don't get away with the idea that mathematics are dry-as-dust. The further you get, the better you will see that high mathematics is imagination of the finest order, kept sane by science. Scientific discovery has been a race between the experimentalist and the mathematician, and often times the latter has come in first.

Next, build up your general physics. The electrical engineer who doesn't know a bit about heat, light, and mechanics is like a bird with one wing. If you can get a course of physical chemistry, hang into it, Electro-chemistry is the coming thing in our line

I have noticed that the majority of young fellows I have had to deal with cannot make a decent dimensioned sketch of a machine part without perspiring over it. Learn to handle the tee-square and compasses till your fingers itch for them. Make a practice of expressing your engineering ideas by firmly-defined sketches on the back of the nearest envelope. Learn to "graph" a curve instinctively—the "graph" is the engineer's shorthand. Carry a slide-rule in your breast-pocket, and learn how to use it without chancing the decimal point.

Having thus cleared a small space in the forest of your ignorance, commence to till the soil by going for general electro-technics. Again avoid specialisation. You may be going to become Marconi's chief assistant, but don't omit to learn the elements of dynamo design. You may turn out to be an electro-chemist, but study telephony just the same. At the same time, you should be laying a broad basis of knowledge by getting hold of the theory of heat engines (if thou understandest the temperature-entropy diagram, blessed art thou among men), hydraulics, strength of materials—they will all come in useful later on.

And amid all this stress of study, don't forget your *self*. You are not sent to College to obtain certain acquirements (things plastered on), but to get an education. Don't assume a superior smile when I remind you that *e duco* means to *draw out*. An engineering education is the development of the gift to make things go that is in you. If you only spend certain hours per day in cribbing notes of other men's thoughts, you will merely become a nasty little prig with a swelled head. Think for yourself. If you don't see a thing first off, stick to it till you *do* see it or fall in a faint.

One word about examinations. I am rapidly coming to the opinion that they are the Works of the Devil. It is better for a man that he should know one thing thoroughly than that he should slur over twenty things sufficiently well to write pretty paragraphs about them on the examiner's foolscap. The man with the carpet-bag head very often finds that he has left the clasp unfastened when he wants something he has bagged. I have known youths who could walk through an exam. on one leg who had to be licked for a year before they assumed practical shape.

Don't be a clever ass in the classroom. You may take it as an axiom that the man who is teaching you is human. Therefore, when you find that he has said on the blackboard that two and six make nine, don't think it is the time of your life because you have found the mistake, and don't lay yourself out to be humorous. You lose caste if you don't behave like a gentleman. I once knew a man who left a good job to become a college lecturer. He was up to his work, but he made the mistake of not having the skin of a pachyderm. The students found this out, and considered it funny. The lecturer therefore got nervous and depressed, and made unnecessary errors. Finally, he emulated the worm by turning. He told them that if he had them in a works behaving like that he would fire them out. As it was, they had paid their money and were entitled to their sport. But as he wasn't going to be the baited bull, he had resigned. Then the students considered him a bigger mug than ever. But they overlooked the fact that, being fresh from actual practice, he could have taught a class of gentlemen something worth knowing.

If you really want to be polite, laugh at the Professor's jokes. The professorial humour is like the judicial joke—it wants seeing. Sometimes it takes half an hour to see it; sometimes the vision never comes. But don't wait till then. Laugh vigorously when the Professor smiles hesitatingly. He will like you better for it, and will possibly spend 10 minutes with you after the lecture to clear up an obscure point.

Finally, when College life is done, and you are taking the class prize in the senior section, remember that you have only just begun. The time has come when you must forget you ever wore a top hat, when the dungaree suit will cover a multitude of sins, when a clean collar (always wear a clean collar—it is the emblem of a gentleman) will be the only relic of the past days. It is a long, high dive from the College to the Workshop. If you don't strip for it, and dive cleanly with a deep plunge, you will make a beastly splash and hurt yourself.—Yours, The Old 'Un.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Bound Volumes of "THE ELECTRICAL ENGINEER," *containing half-year's copies, bound in Dark-Blue Cloth, Gold Lettered, price 8s. 6d. New Volume, January to June, 1904, now ready.*

SINKING FUNDS—HOW DEALT WITH?

The finance of local authorities differs from the finance of individuals and companies in many directions. The terms used in these financial operations differ, although the results may be somewhat analogous. For some years we have had heated discussions as to what constitutes depreciation, in which we have taken a somewhat prominent part, with the result that our views have generally been accepted. It has long since seemed to us desirable that discussion was necessary on the question of sinking and analogous funds, especially as to the realities of these funds and the methods of dealing with them. No doubt once we have started the subject we shall have the usual splitting of hairs and straining at definitions and interpretations. Broad principles, or principles of any kind, are too often ignored by interested controversialists, whose energy is taken up in detecting archaisms or grammatical peculiarities. At present we are not troubling about minor details or differences, but only with the general question. A local authority obtains capital under compulsory legal disabilities of repaying that capital by instalments over a period of time determined by a Government department, and depending upon the nature of the work for the doing of which the capital is required. Hence the capital account of a local authority is a decreasing quantity, vanishing altogether in the course of so many years. The money set aside for the paying of the instalments of capital is usually termed the "sinking fund." We should say that companies have a fund with a more or less similar object and call it "reserve." Our point to-day is how the sinking fund or reserve is dealt with. Of course, if the instalments of the sinking fund are used at once to pay off a certain amount of capital, there is nothing to be said. That is the object for which the fund is created, and when so used is converted to its proper purpose. But financial operations cannot always be conducted in so simple a manner. Investors often require investments of a somewhat permanent character, hence the instalments of the sinking fund are allowed to accumulate till the period arrives when capital can be extinguished. We hold as a fundamental axiom that sinking fund or reserve should always be liquid—that is, subject to no fluctuations in value and realisable at the moment. If equivalent capital cannot be extinguished at once—and the interest paid on capital is greater than the interest obtainable on the sinking fund under these conditions—then the sinking fund is not what it purports or is intended to be. The line in many balance-sheets, "SINKING FUND—*Investments*," may be very misleading. Under the fundamental axiom just enunciated, a sinking fund should not be invested in any business, for the result of no business is certain. Unfortunately, it is becoming more common to invest the sinking fund in extensions of the original undertaking. This we hold to be a mistake of the highest order. The success achieved by investments in commercial undertakings may give a far better result than by dealing with them in any other manner. But that is another question. The fund is prescribed for a certain operation, and it should be an absolute certainty to be always available to be so used. All commercial undertakings are risky, and we say sinking funds should not be risked. If our reading of this matter is correct, a local authority, instead of paying from 2½ to 3½ per cent. on its outstanding capital, may be really paying 20 or 30 per cent. We are not going to attempt to give the exact legal position with regard to the accumulation and investing of sinking funds. Some time ago there was a controversy as to which of two ways was the better for paying the instalment, but the accumulating and

Digitized by Google

investing is a third way, and we think the worst of the three. The exact use of the reserve of a company is hardly to be defined. It has many valuable uses, all of which are good and legitimate. The one use, however, to which we object is that in which it is treated as capital for extension purposes. A company having £3,000 or £3,000,000 capital, with reserve £1,000 or £1,000,000 respectively, uses this reserve to capitalise a company needing £4,000 or £4,000,000. It is then not liquid, but liable to any and all the fluctuations, losses, or gains of commercial enterprise, and thus has its own risks, which, in the nature of affairs, it is not intended to have. It becomes not really reserve, but an undistributed amount by the grace of the shareholders utilised for capital to improve their concern. It is not available in bankruptcy.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

TELEPHONY AT GLASGOW.

SIR,—The paragraph appended to my letter in your last issue shows how difficult it is for a writer not thoroughly familiar with the subject of telephony to be consistent in dealing with telephone questions.

For example, "The Writer on Telephony" (with my statement before him that my argument at Glasgow in 1897 was that the proposed scheme provided too little plant in proportion to working subscribers) says, first, that I am convinced against my will; and then that I hit the goal, though by accident, not by intention. Apart from the fact that goals count, whether made accidentally or otherwise, there seems to be some confusion of thought here.

The "W. O. T." says that I "will not, perhaps cannot, see that there is absolutely no connection between estimates for one thing and costs for another." This is hardly polite, but again it proceeds from confusion of thought and lack of understanding of the subject. The estimate of 1897 was for a "Glasgow municipal exchange" to serve the Glasgow Post Office telephone area. The size of the area has not changed since, though the size of the system has. The arguments made in support of the estimate in 1897, however, were to the effect that the cost per subscriber would not grow materially even if the system grew to 20,000 or 25,000 subscribers, and undoubtedly that was the belief of those interested in the estimate. Apparently what is running in the mind of "W. O. T." is that the estimate was put forward with some such argument as the following: This is an estimate for an exchange of 5,200 subscribers in Glasgow and the neighbourhood, but they must be exactly the subscribers we have picked out, and they must come exactly where we have put our little dots on the maps, and they must number exactly 5,200. Then it will cost £97,833. 3s. 8d., or £18. 16s. 3d. per subscriber. But if we do not get exactly the 5,200 subscribers we have chosen, if they do not come exactly on our little dots, but choose other little dots for themselves, and if they should by any chance exceed 5,200, then the cost will be something quite different—it may be £25, £30, or even £35 per subscriber.

But the estimate was not put forward in that way at all. It was supposed to afford the Glasgow Corporation a reliable guide to the cost per subscriber of telephoning the Glasgow area. The Glasgow area is the same to-day as it was in 1897. It is because the cost of telephoning a large area was not understood in 1897 by the framer of the estimate, that the actual cost per subscriber's line in 1904 is nearly double the estimated cost.

The simple problem set by "W. O. T." is not so simple as it appears, and "W. O. T." will pardon me for saying that he makes it still less simple by confusion of terms and by confusion of expression. He starts by referring to capital cost per *instrument*, and then wants to double the number of *subscribers*. The instrument and the subscriber are two different units; as different, for example, as the lamp and the consumer in electric lighting supply. An instrument may represent a complete subscriber's line, with all the line material and exchange plant that that implies, or it may represent simply a telephone set with a few yards of inside wiring. It may represent several combinations of instrument and line material in between those extremes. The average cost per instrument, then, will depend on the proportion of the different classes of instruments in the system. For example, suppose a system of 1,000 subscribers' lines which has cost £20,000; the average capital cost per subscriber is £20; 200 of the subscribers take inside extension instruments, which cost £3. 10s. each to instal; the total cost then becomes £20,700, and the average cost per instrument £17. 5s. Suppose 400 subscribers take extension instruments, then there is total capital £21,400 and total instruments 1,400; average cost per instrument, £15. 6s. If all the subscribers took extension instruments, the average cost per instrument would be £11. 15s.

This little example shows that you must start fair by estimating according to the unit you are going to adopt throughout. If you estimate by subscribers' lines, you should stick to subscribers' lines, and value the extra instruments in your system at what they cost. If you adopt the instrument as the unit in estimating, you must allow in the estimate, at their proper cost, for a certain proportion of each of the different classes of instruments you are likely to be called upon to provide. In the original Glasgow estimate the cost of the instrument, completely fitted, was put at £3. 14s. If, say, 10 per cent. of extension instruments had been allowed for, there would have been added to the estimate 520 instruments at £3. 14s., or £1,924. The total estimate would have been £99,757, and the average estimated cost per instrument £17. 8s.

As a matter of fact, the Glasgow estimate took the subscriber's line as the unit, not the instrument Indeed, the report of the Glasgow enquiry shows that extension and private instruments were looked upon as a sort of by-product which would bring in extra revenue without requiring extra expenditure of capital. Now that the system has been built, and the results have soared far above all estimates, the instrument is used as the unit in order to arrive at an average figure which comes somewhere near the estimated figure. A single item in the Glasgow statistics shows how artificial this figure really is. The average cost per instrument is put at £28. 2s. 6d. The statistics show that there are 1,081 inside extension instruments. The capital account shows that the total subscribers' and public instruments stand on the books at £50,020, which, for 11,405 instruments, is an average of £4. 7s. per instrument. Therefore, these 1,081 inside extension instruments really stand at £4. 7s. each, or a total of £4,702. 7s. Is it not manifestly absurd to represent them as standing at £28. 2s. 6d. each, or a total of £30,403? And, lest "W. O. T." be misled by a certain ingenious theory of the relation between inside extensions and spare lines, let me point out that an inside extension station is merely an extra facility which can be added or taken away without any regard to spare lines. An inside extension station has no more relation to a spare line than my back drawing-room has to an empty house in the next street.

I trust this little dissertation on lines, instruments, and telephone estimates will be of interest to "W. O. T." and to others of your readers. The subject is of sufficient importance to warrant it being made clear. I now return to "W. O. T.'s" little problem, but I should like to say that the conditions he premises do not apply to the original subject of discussion. The Glasgow area has not only not doubled in radius, but it has not increased by a single square inch between 1897 and the present date. Therefore there is no x about the Glasgow area. The estimate was for a service in the Glasgow Post Office telephone area, which has remained unchanged. The contrast between the results and the estimate is certainly largely due to the effect of the area, but the difference has arisen because of the underlying error in the estimate, which did not give due weight to the effect of area, not, as "W. O. T." seems to suppose, because there has been an increase of the area. This was part of my original criticism of the estimate—that it did not reckon with the effect, in

Digitized by Google

plant required per subscriber, of offering service at a low flat rate over such a large area. As to the problem, of course it is "a fundamental fact" that a controlling factor in determining the size of a telephone plant is area. To put it more correctly, there are three controlling factors—area, traffic, and number of subscribers; to which might be added a fourth, density of distribution of subscribers; and a fifth, rate of growth. It is because these factors were not sufficiently considered in framing the Glasgow estimate of 1897 that that estimate has proved so delusive.

Let me tell "W. O. T." that you cannot proceed with estimates for telephoning great cities by *x*'s and *y*'s. It is the belief that you can which has produced so much confusion. You must study the actual conditions of each individual case, and you must lay out your system and calculate your costs according to those conditions. The conditions vary widely, hardly any two places having identical characteristics from a telephonic point of view. Taking "W. O. T.'s" theoretical problem, if you have a system serving a given area, and you quadruple that area by taking in, as "W. O. T." suggests, double the radius, the average capital cost per subscriber for a uniform flat-rate service will certainly be increased. It will not necessarily be doubled, but its relation to the average capital cost in the smaller area, quality of plant being the same, will be governed largely by the factors above mentioned—the traffic, the number of subscribers obtained, the density of distribution of those subscribers, and the rate of growth to be provided for; while, of course, the local conditions as regards cost of executing work will have their bearing.

I do not wish to add to the length of this letter, which has almost become an essay, by biographical details, as I am essentially a modest man. But "W. O. T."—no doubt an experienced telephonist himself—is good enough publicly to question my experience. I did not put up the first telephones in London. In fact, during the embryonic stage of telephony, the period of overhead single wires, crude apparatus, and rule-of-thumb methods, I had little connection with the telephone industry, although I did some telephone work even then, as your pages, Sir, have recorded in bygone days. But since 1899, or shortly after the time when telephone work began to assume a scientific aspect, I have been intimately connected with telephony, and 13 out of those 15 years I have spent as a worker—a humble worker, it is true, but, nevertheless, an attentive observer—in the system which has grown to be the largest telephone system in the world, and is to-day the best equipped and most efficient telephone system in the world. In those 13 years there have been many changes, many problems, a vast quantity of work executed. I submit that one of average intelligence cannot have spent all that time in close touch with such conditions without acquiring a certain amount of experience applicable to telephone questions of all kinds. New York is the Mecca of telephone engineers from all over the world—from Austria-Hungary to Japan. If "W. O. T." really wants to learn something about telephone work, I should advise him to join the Institution tour and to spend all his time in the telephone buildings of the towns visited. It will be an interesting experience for him.

As a further note on my own limited experience, I may say that I have on several occasions visited the principal European countries with the express object of inspecting the telephone systems, and that there is hardly a capital in Europe, from Christiania to Lisbon or from Amsterdam to Budapest, where I have not inspected the telephone system and gathered information regarding telephonic conditions generally. Whether I have much experience of my own or not, I have certainly gathered a goodly stock of that of others. They say that is how wise men learn.—Yours, etc.,

HERBERT LAWS WEBB.

35, Old Queen-street, S.W., Aug. 5, 1904.

Many thanks, Mr. Editor, for permitting me to see and to reply to Mr. Webb's letter at once. I am sorry to disagree with Mr. Webb, and I have no intention nor desire to be unpolite; rather the contrary, and especially with Mr. Webb, whose energy and abilities I admire. But—and 'tis a big but—my forte, if I have one at all, is plain speaking. I think Mr. Webb in this controversy is wrong; utterly, irretrievably wrong. He is not controversial; he is simply calling a man a liar. That is plain to the point, and intentionally so. Misconception, or ignorance, may be the excuse. These charges are so easy to make, so difficult to refute. Mr. Webb attributed these things to me. I do not object, though I deny the soft impeachment that I lack intelligence, have confusion of thought, or do not understand the subject. In a nutshell, Mr. Webb's criticisms are all based upon an assumption that an 1897 estimate of Mr. Bennett's was an estimate for the work he (Mr. Bennett) has done at Glasgow. It was not. Mr. Bennett emphatically denies it. The two had no connection with each other, and therefore comparisons arising out of figures of estimate and figures of actual cost, etc., are absolutely misleading. Here is what Mr. Bennett says, and I for one accept the statement as the truth, the whole truth, and nothing but the truth:

> The 1897 estimate was made for a special purpose. The Telephone Committee said: "We want you to give us estimates showing what the existing telephone system in Glasgow ought to have cost the National Telephone Company." I took it from the Telephone Company's list that there were practically 5,000 subscribers in the city, and to meet the requirements of the Telephone Committee I prepared an estimate for 5,000 lines: but at the enquiry I said, "If the Town Council proceed with the scheme and entrust me with the work, I shall not recommend a system of 5,000; the present estimate is simply to show the Commissioners what the 5,000 ought to cost. I shall go in for a very much larger scheme." When the time came the Council decided to go in for a very much larger scheme, and called for an estimate, which was, of course, considerably higher. Now, the articles which appear in the *Electric Review*, *Engineering*, and so on, attacking corporation telephones, invariably take the first estimate—the one for 5,000—which was made as a comparative one with the company's system, and compare it with what we have spent on the later and larger scheme. It has been pointed out many times that that is most unfair, and is not to the purpose at all, but they go on doing it all the same. Then Mr. Webb says that even the last estimate has been exceeded. That is true, and for this reason, that the Telephone Committee said to me, some time after we had started, "Take your underground lines out to the suburbs; distribute underground in the city; look well ahead, and avoid reopening of streets; don't be afraid to spend money." As the estimates had only provided for overhead distribution in the city and to the suburbs, the extra expenditure is accounted for by the change of plant which was demanded by the committee, and by the spare plant provided. It is no more reasonable to hold me to the original estimate, than to expect a tramway engineer to lay down a double line or track at the cost estimated for a single line.—"*Corporation Telephones, etc., with full discussion. Vide pp.* 58-59.

All I have written has been written upon the understanding that what Mr. Bennett has said is true. Just a word or two about the expressions in my tag of last week. Mr. Webb misinterprets slightly "a man convinced, etc.," referred to the acceptance by Mr. Webb of the term "academic," as did the word "goal." I agree Mr. Webb has had practical experience, but think that Mr. Bennett's practical experience is much greater, hence prefer the greater to the less. That means no disparagement to Mr. Webb, for sooner or later youth must tell as against age. The "old un's" sometimes stereotype their experience, won't and can't go with the times, and then the younger push them aside. It is just possible that Mr. Bennett may be held to be one of the stereotypists. As yet I imagine he has not entered that category, but is wide enough awake to accept improvements. Here is the point where I think Mr. Webb and other energetic men with him are doing good work. It is good for them to discuss whether the system adopted by Mr. Bennett is antiquated and less efficient than another, and for us to have his reply. Stick to such criticism and I shall praise, not blame. My objection is that when a man makes a plain, straightforward, considered statement, it is not believed, and hence a scarecrow is set up to be knocked down. If that kind of thing pleases Mr. Webb, it does not please me, and I say so. I agree the units "instruments" and "subscribers" are not the same, but Mr. Webb can take which he chooses. He evidently agrees with me, that area of which the units are spread, not the units, determine largely (I agree not wholly) the cost of trenching, ducts, etc. I never intended to imply that *x*'s and *y*'s would enable you to estimate. I gave a simple

Digitized by Google

problem to indicate that x and y were not necessarily multiples of each other. It was Mr. Webb who rather suggested they ought to be, by hinting there was something abnormal in length of wires, trenching, and ducts, not proceeding in proportionate multiple as did the units. I have no objection to fight out telephonic questions, but until men's words are honourably accepted what is the use?—W. O. T.

ARTIFICIAL LOADS.

SIR,—In his zeal to emphasise the importance of certain articles and discussions which occurred at periods ranging from "some years ago" to "2½ years ago," the critic yclept "Yrreb" has, I venture to suggest, viewed the article on "Artificial Loads," appearing in your issue of the 22nd ult., from a somewhat prejudiced standpoint.

So far as I can see, the article claims no originality, but is a very useful summary of methods in use for obtaining an artificial load, with the description of a conveniently compact apparatus for this purpose. The whole question is begged in the critic's phrase, "with ample electrode surface." There is not much room to spare in many stations for auxiliary plant of this kind, and any data giving the minimum bulk necessary are very welcome. Mr. F. W. Davies points out the desirability of doing without acids or alkalies to reduce the resistance of the water, and emphasises the alternative method—a rapid changing of the water.

The jest which is attempted regarding the length of test run is futile, as the critic will see on a more careful perusal of the article. A permanent water resistance should have some approximation to constancy. Nothing is more aggravating than to waste steam while "playing about" with the load. My own experience has been that not only does the resistance of canal water vary with the period of the year, but fluctuates largely during a test. Repeatedly the load in an engine under test fell at one instant to almost half value, at another time a heavy excess load being thrown on the engine, owing possibly to a film of oil carried into the tank with such water. How can accurate cards be taken under such conditions?

If the insulation of an alternator or dynamo cannot stand the earthing of one pole, how will it go on when an "earth" develops on the cables? No supply company will give an undertaking to their contractors that "earths" will not occur. Added to this is the risk to human life in working with unearthed apparatus (particularly with bubbling water) at high potentials.

Your critic does good by drawing attention to previous notes on the same subject, but the tone of his letter suggests that the last word on artificial loads was long ago said. It is humiliating, therefore, to have to say that busy engineers, unable to find time for research, are always glad to have practical ideas brought anew to their notice.—Yours, etc.,

A.M.I.C.E.

SIR,—With reference to "Yrreb's" criticism of my article in your issue of July 22, I do not, of course, claim originality for the testing tank described; such methods are, I am aware, in common use. It was included in the article because, having been thoroughly successful, the dimensions and general design might be of use to others interested in the subject. I would remind "Yrreb" that, perhaps, all are not so well up in testing tanks as he, and that the publication of successful designs is the only method of forwarding general knowledge. I cannot at all agree that it is not always advisable to earth the outer tank—that is, when machines of 500 volts and over are being tested. The precaution is obvious and necessary, considering that the lives of the attendants are at stake. Besides, in practice a 500-volt direct-current machine, or high-tension single-phase alternator, will run with its negative or outer earthed; therefore, what is the harm in testing it under its proper running conditions? Such a proceeding obviously reduces the insulation resistance, but only to the amount that the machine will be required to work at in practice, and if it is going to fail, it is surely better that this should happen on test than when in regular commission. Regarding the question as to how long I would run a test, "Yrreb" has completely misunderstood me; my remarks were solely applied to station work. It is surely possible either in a testing shop or central station that two similar machines may have to be tested at different seasons of the year, in which case, from the causes stated, an arrangement fitted *in* a canal, although suitable, say, in summer, may be absolutely useless in the winter, and *vice versâ*. Canals doubtless do vary in this respect, but a word of warning may cause preliminary tests to be made before installing a permanent arrangement, and so, in a bad case, save money and trouble in subsequent alterations. In any case, from my experience of various canal waters, I do not like them, and have known the conductivity of a tank fed with such to alter considerably in a few minutes owing to a local stream of impurities having found its way in.

I am in accordance with "Yrreb" as regarding the use of chemicals, and in my article distinctly state that it is best to do without them. I, however, recognise that it is possible occasion may arise when a small addition might be of great service in getting, say, the last few amperes of the load, and in such a case I advocate the use of salt or soda over sulphuric acid. We cannot always have perfect apparatus, and sometimes this sort of thing is necessary. In anything but the smallest quantities, say for the above purpose, the use of chemicals is a mistake.—Yours, etc.,

F. H. DAVIES.

RE BELT CALCULATIONS.

SIR,—Referring to the questions which appeared in the *Electrical Engineer* for July 29, 1904, regarding some method for determining the best or proper length of belt drive in cases where the driving and driven pulleys are of different diameters, I beg to say that a good method is to add together both the pulley diameters and multiply the sum by the ratio of the two diameters, when the result will give the most useful length of drive for any reasonable ratios. For example, take a case where a 3ft. diameter pulley is driving a 1ft. diameter pulley. Then by the rule $(3+1)\times 3=12$, which, measured in feet, will be the distance required between the two shaft centres. Taking two more pulleys of 5ft. and 2ft. diameters respectively, then $(5+2)\times 2{\cdot}5=17\frac{1}{2}$ft. distance from centre to centre; or, again, a 3ft. diameter pulley driving one 11ft. diameter, then $(3+11)\times 3{\cdot}7=51{\cdot}8$ft. approximately. It will be seen on working out that by using this method both the angle of belt, which is about 10deg., and the arcs of contact are fairly constant for any reasonable ratios of pulley diameters. It can also be shown that anything above these lengths is simply a waste of leather.

With reference to the question by "N. L. G." *re* belt thickness, I may say that, generally speaking, it is only in cases where a belt is running on a pulley of small diameter that the question of thickness of leather need be considered. A rule I have always used is as follows: take $\frac{1}{16}$ of the square root of the diameter of the pulley in inches, and the result will be the most serviceable thickness of leather to employ for small pulleys.

For example, take a 2in. diameter pulley, then $(\frac{1}{16}\sqrt{2})$ inches $=\frac{3}{32}$in. thickness. Take another pulley, 4in. diameter, then $(\frac{1}{16}\sqrt{4})$ inches $=\frac{1}{8}$in. thickness; or a 6in. diameter pulley, then $(\frac{1}{16}\sqrt{6})$ inches $=\frac{3}{32}$in. thickness; again, a 9in. diameter pulley, then $(\frac{1}{16}\sqrt{9})$ inches $=\frac{3}{16}$in. thickness; again, a 16in. diameter pulley, then $(\frac{1}{16}\sqrt{16})$ inches $=\frac{1}{4}$in. thickness. This rule is only needed for diameters less than 24in.; above this any thickness of leather may be employed. Both these rules are original, and will be found useful and thoroughly consistent with good practice. Yours, etc.,

THE WRITER OF THE ARTICLE.

P.S.—Another way of stating this would be to take a pulley, say, 9in. diameter. Then by the rule the $\sqrt{9}=3$, and this should be understood as being $\frac{3}{16}$in., which would be the proper thickness of leather for that pulley.

"THE OLD UN'S" ADVICE.

SIR,—I have enjoyed reading the letters of your humorous contributor immensely, and hope "The Old Un" will take my remarks in the spirit in which they are

Digitized by Google

written. It seems to me that working, in order to become acquainted with the practical side of engineering, is one of the ways not likely to recompense "a young one." As far as my experience goes, it is the "paper engineer" who rules the roost, who gets *all* the honour and *most* of the dollars. Let the aspirant to success as an engineer throw work, like physic, to the dogs; let him rather go in for study, and make as many influential friends as possible. Learn not so much how to *do* things as how to *talk* about doing them. Theory and practice are both good, but the better of the two is theory.—Yours, etc., M. M.

ELECTRIC TRAMWAYS IN THE EAST.

It is satisfactory to learn that, despite the keen competition which exists in the East for electrical work, at least one English firm is able to secure large and inclusive contracts for electric tramways and lighting. Following up previous successes, Messrs. Dick, Kerr, and Co., Limited, have recently obtained a contract for electric tramway plant and material for Bangkok tramways, owned by the Siamese Tramways Company, Limited. The contract includes power-house equipment, which consists of three 200-kw. 500-volt direct-current generators coupled direct to three Browett-Lindley vertical compound engines, and the usual accessories, including surface condensers, pumps, etc. There are also 40 single-motor equipments of the firm's 25B type mounted on Brill 21E trucks, and the whole of the rails, fishplates, tiebars for the line, which has a total length of 13½ miles.

Of the other contracts which Dick, Kerr, and Co. are carrying out, the Mandalay tramways have just recently been successfully opened by the Lieutenant-Governor of Burma, Sir Hugh Barnes, K.C.S.I., K.C.V.O., and the system is now in operation. We shall shortly be publishing full details of these tramways; in the meantime we would mention the principal features of the system. The total length of the tramways is 12 miles of single track, laid to a gauge of 3ft. 6in. with rails of the girder type weighing 85lb. per yard. The overhead equipment is on the span-wire system, and is of a very neat and rigid design. The rolling-stock consists of 24 single-deck, open, cross-bench cars to accommodate 48 passengers, built for Dick, Kerr, and Co. by the Electric Railway and Tramway Carriage Works, Preston. The cars are mounted on Brill maximum trucks, each car being supplied with a complete electrical equipment, consisting of 25B motors with DB1 form "C" controllers. The power-house equipment consists of three direct-current, compound-wound, 200-kw., 400 revolutions per minute, 500-550-volt generators, direct coupled to three Belliss compound engines. The switchboard is in accordance with the standard traction practice, and consists of four feeder panels, three generator panels, one testing panel, and one panel for motor and lighting circuits.

The electric tramways of Hong Kong are rapidly approaching completion, the contractors again being Messrs. Dick, Kerr, and Co. The total length of single track is 14½ miles, and is laid to a gauge of 3ft. 6in. with girder type rails weighing 86lb. per yard. The overhead line within the city is centre-pole construction, but outside the city boundary is equipped on the side-pole system. The power-house is as nearly as possible in the centre of the system. The plant consists of two direct-current 300-kw. railway generators of the multipolar type, compound-wound, running at a speed of 100 revolutions per minute at 500 volts, direct coupled to the main shaft of two engines built by Yates and Thom. In addition to the two traction sets, two combined sets for arc and incandescent lighting of the depôt have been installed. The switchboard consists of two generator panels, two feeder panels, three lighting panels, one main station panel, and one Board of Trade panel. The boiler-house contains two Babcock and Wilcox watertube boilers and the usual accessories. Twenty-six single-deck cars are provided, 10 being of the combined type, with an enclosed portion in the centre and an open platform with seats at either end, and have a seating capacity for 32 passengers; the remaining 16 cars are of the open cross-bench type, to seat 48 passengers. Each car is mounted on a Brill 21E truck, and is fitted with two standard four-pole series-wound motors of 25 h.p., and at either end of the car is one of the firm's standard DB1 form C controllers. As this is the pioneer system of electric traction in China, it is to be hoped the venture will meet with a well-deserved success, and that electrically-equipped lines will shortly be laid in other parts of the Celestial Empire.
